116—130).—The dissociation const.,  $K$ , of an acid or base and the ionic product of the solvent,  $K_1$ , may be calc. from the potential jumps at the beginning of the titration and at the equiv. point or from the potentials as the beginning, at half-neutralisation, and at the equiv. point. For solutions of  $\text{o-NH}_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$  in aq. AcOH  $K$  and  $K_1$  have been determined for solvents with 0.8—20% H<sub>2</sub>O; both fall rapidly with the [H<sub>2</sub>O] and the precision of titration with bases increases. Amines cannot be titrated in AcOH solution to which Ac<sub>2</sub>O has been added to effect dehydration, for they undergo acetylation, but satisfactory results are obtained in presence of Ac<sub>2</sub>O if a known amount of HClO<sub>4</sub> is added before adding the amine to the AcOH; excess of acid may be titrated back with a non-acetyltable base. R. C.

**Geometrical isomerism of strong bases.** A. GRUNBERG and D. RJAFTSCHIKOV (Acta Physicochim. U.R.S.S., 1935, 3, 555—572).—The *trans* form of  $\text{Pt}(\text{NH}_3)_2(\text{OH})_2$  is more alkaline than the *cis* form; the difference increases with the concn., and also in the presence of ions capable of forming complexes, the effect decreasing in the order I<sup>-</sup>, CNS<sup>-</sup>, Br<sup>-</sup>, Cl<sup>-</sup>, SO<sub>4</sub><sup>-</sup>, NO<sub>3</sub><sup>-</sup>. Potentiometric titrations with a glass electrode give  $K_1 = 0.63 \times 10^{-7}$ ,  $K_2 = 1 \times 10^{-10}$  for the *trans* form and an average val.  $K = 0.16 \times 10^{-7}$  for the *cis* form.

C. R. H.

**Acid-base dissociation constants in mixtures, and their connexion with individual ion activities.** I. C. D. RIETZ (Svensk Kem. Tidskr., 1936, 48, 165—175).—A discussion of the above and related problems.

D. C. J.

**Potentiometric investigation of electrolytic dissociation. IV. Anion affinity of copper, zinc, cadmium, silver, and hydrogen ions.** E. FERRELL, J. M. RIDGION, and H. L. RILEY [in part with S. CHAMBERS] (J.C.S., 1936, 1121—1126).—Potentiometric data afford evidence of the formation of complex ions in certain of the following cases: Zn<sup>++</sup> with CNS<sup>-</sup>, S<sub>2</sub>O<sub>3</sub><sup>-</sup>, NH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub><sup>-</sup>, OAc<sup>-</sup>, Cl<sup>-</sup>, Br<sup>-</sup>; Cd<sup>++</sup> and Ag<sup>+</sup> with CN<sup>-</sup>, CNS<sup>-</sup>, S<sub>2</sub>O<sub>3</sub><sup>-</sup>, ClO<sub>3</sub><sup>-</sup>, OAc<sup>-</sup>. The order of decreasing anion affinity is Ag<sup>+</sup> > Cu<sup>++</sup> > Cd<sup>++</sup> > Zn<sup>++</sup>. No evidence of complex ions of CN<sup>-</sup> and NH<sub>2</sub>CH<sub>2</sub>CO<sub>2</sub><sup>-</sup> with H in which H has a covalency of 2 was obtained. Pt-black and pptd. Au dissolve in conc. aq. KCN and H<sub>2</sub> is evolved.

J. G. A. G.

**Solvation and complex formation in solutions of electrolytes.** V. FINKELSTEIN (Acta Physicochim. U.R.S.S., 1935, 3, 541—554).—Cryoscopic data for solutions of AsCl<sub>3</sub>, AsBr<sub>3</sub>, and SbCl<sub>3</sub> in C<sub>6</sub>H<sub>6</sub> containing Et<sub>2</sub>O, AcOH, or PhNO<sub>2</sub> as solvating agent indicate that the lowering of f.p. oc the ratio of the mol. concns. of solvating agent and halide. The theoretical lowering, assuming absence of association, dissociation, and solvation, is > that found, the discrepancy increasing with the concn. of the solvating agent. Raman spectra of Et<sub>2</sub>O solutions of the same electrolytes afford no evidence for the formation of new compounds.

C. R. H.

**Two inorganic complexes having in solution an exceptionally high Verdet constant.** R. LUCAS and F. GALLAIS (Trans. Faraday Soc., 1936, 32, 973—975).—For saturated solutions of HgI<sub>2</sub>+KI

and of  $\text{BiI}_3 + \text{KI}$ , in which complex salts are present,  $[\alpha]$  is 18 to 28 times that of  $\text{H}_2\text{O}$ . O. J. W.

**Thermodynamics of chemical equilibria and reaction rates.** M. G. EVANS and M. POLANYI (Trans. Faraday Soc., 1936, 32, 1333—1360).—Theoretical. Subjects discussed include: linear relations between chemical free energies, thermodynamics of the transition state, linear relations accompanying structural changes, relation between entropies and heats of dissolution, collision factors in solution, influence of viscosity on bimol. reaction rate in solution, relations of energy and entropy based on the Nernst theorem, relevance of activation energies derived from energy surfaces. E. S. H.

**Activity coefficients of lithium chloride and potassium iodide in ethyl alcohol by the b.p. method.** J. N. PEARCE and M. L. McDOWELL (J. Physical Chem., 1936, 40, 845—852).—The b.p. elevations for 0.01—0.65*N* solutions of  $\text{LiCl}$  and 0.01—0.15*N* solutions of  $\text{KCl}$  in  $\text{EtOH}$  correspond closely with those which would be produced by undissociated solute mols. This is attributed to the existence of simple or chain ions in equilibrium with paired ions or quadrupoles, the formation of the latter being favoured by the low dielectric const. of  $\text{EtOH}$ . The activity of the  $\text{EtOH}$  is almost the same for equal concns. of  $\text{LiCl}$  or  $\text{KCl}$ , but the activity coeffs. of the ions of  $\text{KCl}$  are slightly  $>$  for those of  $\text{LiCl}$ . J. W. S.

**Specific thermodynamic properties of aqueous solutions of uni-univalent electrolytes.** E. A. GUGGENHEIM (Phil. Mag., [vii], 22, 322—336).—Formulae previously deduced (cf. A., 1935, 446) are applied to f.-p. data, and the osmotic and activity coeffs., for the chlorates, perchlorates, nitrates, formates, and acetates of  $\text{Li}$ ,  $\text{Na}$ , and  $\text{K}$ , are found to be in good agreement with experiment. For  $\text{NaCl}$  solutions e.m.f. data are also considered and results tabulated. General results for uni-univalent electrolytes are considered. N. M. B.

**Thermodynamics of silver fluoride-water mixtures.** W. J. HELD and K. JELLINEK (Z. Elektrochem., 1936, 42, 608—623).—Vals. are recorded for solubility, f.p.,  $d$ , mol. heat of mixing, heat of dilution, molar heat content, activity coeffs., v.p. of  $\text{H}_2\text{O}$  over the solutions, and free energy changes. E. S. H.

**Simple numerical relationships in binary eutectic mixtures.** D. STOCKDALE (Trans. Faraday Soc., 1936, 32, 1365—1369; cf. this vol., 151).—Published data for eutectics containing two salts with a common ion, and org. eutectics, give indefinite evidence. A plea for more exact data is urged. E. S. H.

**M.p. diagram of polycomponent systems. I—IV.** Y. KONISHI (J. Soc. Chem. Ind. Japan, 1936, 39, 209—211b).—A method is described by which the change of a given property (e.g., m.p.) with composition in polycomponent systems may be represented by rectangular co-ordinates, and illustrated by the systems  $\text{MgF}_2$ — $\text{BaF}_2$ — $\text{LiF}$  and  $\text{MgF}_2$ — $\text{BaF}_2$ — $\text{CaF}_2$ — $\text{LiF}$ . The lowest m.p. in the former is  $645^\circ$  with a wt. ratio of components =

1 : 1.65 : 0.73, and in the latter  $603^\circ$  with a ratio = 1 : 1.65 : 0.55 : 0.73. T. W. P.

**Isotherms of the system calcium oxide-water.** V. RODT (Z. anorg. Chem., 1936, 228, 175—177).—Data for  $20^\circ$  reveal only one hydrate,  $\text{CaO} \cdot \text{H}_2\text{O}$ . E. S. H.

**System methylamine-calcium chloride.** A. MAILLARD (Compt. rend., 1936, 302, 187—189).—The data refer to  $-16^\circ$  and  $24^\circ$ . Evidence for the formation of compounds represented by  $\text{CaCl}_2 \cdot x\text{NH}_2\text{Me}$  with  $x=2, 4, 6$ , and 8 has been obtained. J. G. A. G.

**Dissociation pressure of vanadium pentoxide.** N. NASU (J. Chem. Soc. Japan, 1935, 56, 666—669).—Measurements at  $220$ — $325^\circ$  lead to the following data:  $\text{V}_2\text{O}_5 = \text{V}_2\text{O}_4 + 0.5\text{O}_2$ ,  $\Delta H_{298} = 14,300$  g.-cal.,  $\Delta F_{298} = 7900$  g.-cal.,  $\Delta S = 15.6$  g.-cal. per degree;  $\text{V}_2\text{O}_5 + \text{H}_2 = \text{V}_2\text{O}_4 + \text{H}_2\text{O}$ ,  $\Delta H_{298} = -43,500$ ,  $\Delta F_{298} = -44,800$ ,  $\Delta S = -4.4$ . The lattice energy of  $\text{V}_2\text{O}_5$  is 9772 g.-cal. CH. ABS. (e)

**Solid-liquid equilibria in binary and ternary systems in which mixed crystals are formed. IV. (1) Camphor-bromocamphor. (2) Camphor-bromocamphor-borneol.** K. HRYNAKOWSKI, H. STASZEWSKI, and M. SZMYT (Z. physikal. Chem., 1936, 177, 95—102).—In the system camphor-bromocamphor there is complete miscibility in the solid state and the f.-p. curve has a min. Ternary mixed crystals are probably formed in the second system. It is suggested that ternary mixed crystals are formed in those ternary systems in which mixed crystals are formed in each of the three binary systems. R. C.

**Affinity. LXVII. Tensimetric analysis of higher palladium sulphides.** W. BILTZ and J. LAAR. **LXVIII. System manganese-sulphur; structure and synthesis of hauerite ( $\text{MnS}_2$ ).** W. BILTZ and F. WIECHMANN. **LXIX. System nickel monosulphide-nickel disulphide-sulphur.** W. BILTZ [with A. VOIGT, K. MEISEL, F. WEIRKE, and P. EHRLICH] (Z. anorg. Chem., 1936, 228, 257—267, 268—274, 275—296; cf. A., 1935, 1335).—LXVII. Thermal, tensimetric, and X-ray analyses confirm the existence of  $\text{Pd}_4\text{S}$ ,  $\text{Pd}_5\text{S}_2$ ,  $\text{PdS}$ , and  $\text{PdS}_2$ .

LXVIII. The S v.p. of  $\text{MnS}_2$  at different temp. has been determined. The conditions of synthesis of  $\text{MnS}_2$  from  $\text{MnS}$  and S are discussed.

LXIX. Tensimetric data show that no compound exists between  $\text{NiS}$  and  $\text{NiS}_2$ . The transformation temp. of  $\text{NiS}$  from trigonal to hexagonal is  $396^\circ$ . E. S. H.

**Relations of beryllium to the [zinc] group and the alkaline-earth metals. I.** W. SCHRODER [with E. NEUMANN and J. ALTDORF] (Z. anorg. Chem., 1936, 228, 129—159).—Equilibrium data for the systems  $\text{BeSO}_4$ — $\text{H}_2\text{O}$ ,  $\text{ZnSO}_4$ — $\text{H}_2\text{O}$ , and  $\text{BeSO}_4$ — $\text{ZnSO}_4$ — $\text{H}_2\text{O}$  at  $0$ — $100^\circ$  are recorded. E. S. H.

**Reduction equilibrium of metallic oxides. VII. Determination of the thermal diffusion effect in mixtures of hydrogen and oxygen.** Z. SHIBATA and H. KITAGAWA. **VIII. Effect of thermal diffusion on the determination of equilibrium constants in the systems  $\text{FeO} + \text{H}_2$ ,  $\text{Fe} + \text{H}_2\text{O}$  and  $\text{Fe}_3\text{O}_4 + \text{H}_2\text{O} \rightleftharpoons 3\text{FeO} + \text{H}_2\text{O}$ .** Z. SHI-

BATA (J. Chem. Soc. Japan, 1935, 56, 722—735, 736—744; cf. A., 1933, 783).—VII. One end of the vessel containing the mixture was kept at room temp. and the other was heated to 721—1021°. The diffusion effect is discussed on the basis of the kinetic theory.

VIII. A crit. discussion. Thermochemical data are calc., account being taken of the effect of thermal diffusion. CH. ABS. (e)

System  $2\text{MnO}_3\cdot\text{SiO}_2 + \text{FeS}$ . A. S. GINZBERG, B. P. SELIVANOV, S. I. NIKOLSKI, and M. M. VOROVITSCH (Rep. Inst. Met. (Leningrad), 1933, No. 14, 111—115).—Inflection points in the heating curves are recorded and discussed. CH. ABS. (e)

Systems of sulphur and various metals. E. JÄNECKE (Z. Elektrochem., 1936, 42, 373—377).—Complicated systems of S and three metals can be represented by fairly simple diagrams when the ternary limiting systems are known. O. J. W.

Reciprocal salt pair  $(\text{K}_2\text{—Ca})(\text{Cl}_2\text{—SO}_4)$ . E. JÄNECKE and W. MÜHLHÄUSSER (Z. anorg. Chem., 1936, 228, 241—248).—Equilibrium in the fused mixture has been studied by thermal and microscopical methods. E. S. H.

Free energy of formation of more noble metal fluorides compared with other analogous metal halides. W. JAHN-HELD and K. JELLINEK (Z. Elektrochem., 1936, 42, 401—421).—From e.m.f. measurements the free energy, heat of formation, and entropy change in the formation of the following compounds at 25° have been calc.:  $\text{AgCl}$ ;  $\text{PbCl}_2$ ;  $\text{AgBr}$ ;  $\text{CuBr}$ ;  $\text{PbBr}_2$ ;  $\text{PbF}_2$ ;  $\text{AgF}\cdot 2\text{H}_2\text{O}$ ;  $\text{AgF}\cdot 4\text{H}_2\text{O}$ ;  $\text{CuF}_2\cdot 2\text{H}_2\text{O}$ ;  $\text{CdF}_2$ ;  $\text{ZnF}_2\cdot 4\text{H}_2\text{O}$ ;  $\text{NiF}_2\cdot 4\text{H}_2\text{O}$ ;  $\text{CoF}_2\cdot 4\text{H}_2\text{O}$ ;  $\text{NiCl}_2\cdot 6\text{H}_2\text{O}$ ;  $\text{CoCl}_2\cdot 6\text{H}_2\text{O}$ . The results are compared with those derived from equilibrium data in the reduction of the halides with H. Measurements of the  $\text{H}_2\text{O}$  v.p. over saturated  $\text{CoCl}_2\cdot 6\text{H}_2\text{O}$  and  $\text{NiCl}_2\cdot 6\text{H}_2\text{O}$  solutions, and of the  $\text{HBr}$  v.p. over 6*N*- $\text{HBr}$  solution at 15°, 25°, and 35° are recorded. O. J. W.

Electron affinity of free radicals. XI. Free energy of addition of sodium to ketones and unsaturated hydrocarbons. H. E. BENT and N. B. KEEVIL (J. Amer. Chem. Soc., 1936, 58, 1367—1371; cf. this vol., 1952).—Data for the addition of Na to  $\text{COPh}_2$ ,  $\text{CO}(\text{C}_6\text{H}_5\text{Ph})_2$ , fluorenone, tetraphenylcyclopentadienone,  $\text{C}_2\text{H}_2\text{Ph}_4$ , stilbene, and anthracene have been determined. With  $\text{COPh}_2$  the Na becomes attached to the O. E. S. H.

Solubility of non-electrolytes. III. Entropy of hydration. J. A. V. BUTLER and W. S. REID (J.C.S., 1936, 1171—1173).—Entropies of hydration,  $\Delta S$ , of ten monohydric aliphatic alcohols and five other compounds have been calc. Contrary to earlier views, the changes of  $\Delta F$  (free energy of hydration) and  $\Delta H$  (heat of hydration) are in opposite directions as the alcohol series is ascended.  $\Delta S$  for 17 gases and vapours has been calc. from solubility data.  $\Delta S$  is little influenced by the constitution of the solute mol., but depends mainly on the size. The solute mols. probably disorient  $\text{H}_2\text{O}$  to an extent which increases with the size, giving the solute an abnormally low partial entropy in the solution. J. G. A. G.

Thermochemistry of the alkali and alkaline-earth nitrites. M. DODÉ (Compt. rend., 1936, 203, 365—367).—The heats of formation and of dissolution are recorded for the nitrites of Li, Na, K, Ca, Sr, and Ba. R. S.

Secondary calibration substance for combustion calorimeter for gases and vapours. Heat of combustion of isopentane vapour. W. A. ROTH and H. PAHLKE (Angew. Chem., 1936, 49, 618—619).—*iso*Pentane vapour is recommended as a secondary standard. The heat of combustion at 20.5° is  $11,690 \pm 5$  g.-cal. per g. at const. vol., and  $11,722 \pm 5$  g.-cal. per g. at const. pressure. E. S. H.

Heats of dissolution and dilution of salts from extreme dilution to saturation. V. Barium chloride. E. SCHWARTZ and H. COBLANS (Z. physikal. Chem., 1936, 176, 430—443).—Thermal data are recorded for  $\text{BaCl}_2$  solutions. With increasing concn. the differential heat of dissolution passes through a min. and then through a max. In its thermochemical behaviour in solution  $\text{BaCl}_2$  resembles the Li rather than the K halides. R. C.

Heat of solvation of some univalent ions in water, methyl and ethyl alcohol. K. MISCHTSCHENKO (Acta Physicochim. U.R.S.S., 1935, 3, 693—702).—The heats of solvation of  $\text{LiCl}$ ,  $\text{NaCl}$ ,  $\text{NaBr}$ ,  $\text{NaI}$ ,  $\text{KI}$ , and their ions in  $\text{H}_2\text{O}$ ,  $\text{MeOH}$ , and  $\text{EtOH}$  have been calc. from existing data for the integral heat of dissolution and from calc. vals. for the lattice energy, assuming that heat of dissolution = lattice energy + heat of solvation. The heat of solvation is approx. the same in  $\text{EtOH}$  as in  $\text{MeOH}$ , the val. in  $\text{H}_2\text{O}$  being slightly less. C. R. H.

Ionic radii and heat of hydration. A. VOET (Trans. Faraday Soc., 1936, 32, 1301—1304).—A linear relation exists between ionic radii and reciprocal heats of hydration of positive ions. An explanation, based on the electrostatic theory, is advanced. E. S. H.

Conductivity of the double sulphates of the magnesium series in aqueous solution. B. FEDOROV (Compt. rend., 1936, 203, 367—369).—The conductivity of the double salts  $\text{K}_2\text{M}^{\text{II}}(\text{SO}_4)_2$  ( $\text{M}^{\text{II}} = \text{Mg}$ ,  $\text{Zn}$ ,  $\text{Ca}$ ,  $\text{Cu}$ ,  $\text{Mn}$ ,  $\text{Fe}^{\text{II}}$ ,  $\text{Ni}$ , or  $\text{Co}$ ) is < that of the sum of the conductivities of the component salts at all concns.  $> 0.0001M$ . R. S.

Electrical conductivities of aqueous solutions of sodium dodecyl sulphate and sodium hexadecyl sulphate at different temperatures. O. R. HOWELL and H. G. B. ROBINSON (Proc. Roy. Soc., 1936, A, 155, 386—406).—Data for the solutions have been obtained over a wide concn. range at 20° to 100°. The  $\Lambda\text{—}\sqrt{c}$  curves consist of three distinct parts: over the first, the fall in  $\Lambda$  is linear (as for a simple electrolyte), and the results are explained on the Debye-Huckel theory; over the second, the fall in  $\Lambda$  is very rapid and previous theories to account for this are shown to be untenable, and an anionic network is postulated which offers a satisfactory explanation; over the third,  $\Lambda$  rises to a small max. and falls again. Confirmation of the existence of micelles over the last range is afforded by the fact that the transport no.

of the anion retains its high val. of about 1. The ionic micelle is not highly charged, the charge probably being  $\geq 1$  or 2 units. It is suggested that the initial stage of micelle formation with  $C_{12}H_{25}\cdot SO_4Na$  probably involves  $Na^+ + [D_4Na_3]'$ . L. L. B.

**Conductivity of alkali-water-acetone solutions** [at  $0^\circ$ ]. W. H. HATCHER and C. T. MASON (Canad. J. Res., 1936, 14, B, 195—203).—The sp. conductivity,  $\kappa_w$ , of aq. NaOH and KOH is  $>$  that of aq.  $COMe_2$ -alkali. The sp. conductivity of the mixture,  $\kappa_m$ , is related to the viscosities,  $\eta_w$  and  $\eta_m$ , and the dielectric const.,  $\epsilon_w$  and  $\epsilon_m$ , of  $H_2O$  and the mixtures, respectively, thus  $\kappa_m = 1.08\kappa_w\eta_w\epsilon_m/\eta_m\epsilon_w$ .

J. G. A. G.

**Dispersion of electrical conductivity and dielectric constant in dilute solutions of strong electrolytes.** J. W. WILLIAMS and O. M. ARNOLD (Acta Physicochim. U.R.S.S., 1935, 3, 619—632).—Vals. of  $\kappa$  and  $\epsilon$  for strong electrolytes of several valency types in extremely dil. aq. solution are in satisfactory agreement with the Debye-Falkenhagen dispersion theory. The vals. of  $\epsilon$  indicate that any decrease in  $\epsilon$  resulting from saturation of the liquid mols. by the electric fields arising from the dissolved ions is small or even negligible. C. R. H.

**Determination of surface conductance from measurements on suspensions of spherical particles.** H. FRICKE and H. J. CURTIS (J. Physical Chem., 1936, 40, 715—722).—From the differences in the conductivity of solutions of KCl, HCl, and  $Na_2CO_3$  and of suspensions of glass and kaolin particles (diameter 0.6—3.4  $\mu$  in these solutions at 0.5—100 kc.), the surface conductivities of the particles have been calc. The results are compared with the vals. calc. on the assumption of a diffuse double layer, but the latter only partly explains the observations. There is also a surface capacity, indicating current transport at the solid surface, which may account for the variation of the surface conductivity with the frequency. J. W. S.

**Space-charge in a conducting electrolyte.** W. SCHRIEVER (Physical Rev., 1935, [ii], 47, 327).—Space-charges in the system  $Cu[0.0024N\cdot CuSO_4]Cu$  have been determined. L. S. T.

**Transference number of lanthanum chloride as a function of concentration.** G. JONES and L. T. PRENDERGAST (J. Amer. Chem. Soc., 1936, 58, 1476—1482).—Over the concn. range 0.0038—1.0M, the transference no. at  $25^\circ$  varies from about 0.47 to 0.30. Equations relating transference no. to concn. are discussed. E. S. H.

**Ionic transference numbers in Cellophane membranes.** T. TEORELL (J. Gen. Physiol., 1936, 19, 917—927).—The apparent cationic transport nos. for HCl, LiCl, NaCl, KCl, and  $NH_4Cl$  in Cellophane are all  $>$  the corresponding vals. in  $H_2O$ ; the relative cation mobilities show an increase of about 40%. F. A. A.

**Potentials of silver-zinc alloys.** G. I. PETRENKO and E. E. TSCHERKASCHIN (Z. Elektrochem., 1936, 42, 398—400).—Measurements of the p.d. of the cell  $Zn|N\cdot ZnSO_4|Ag-Zn$  alloy indicate that  $Ag_2Zn_3$  and  $AgZn$  are the only compounds formed. This agrees with thermal data. O. J. W.

**Amalgam concentration cells and electrodes of the second kind in non-aqueous solvents.** H. ULICH and G. SPIEGEL (Z. physikal. Chem., 1936, 177, 103—115).—Na amalgam dropping electrodes have been prepared giving a const. potential, independent of the rate of dropping, when the latter is sufficiently high, and the e.m.f. of amalgam concn. cells has been measured. With a  $COMe_2$ , MeOH, or  $C_5H_5N$  solution of NaI as electrolyte, the relation between the activity coeff.,  $f$ , and concn.  $c$ , for the Na in the amalgam is the same as when  $H_2O$  is the solvent, but with MeCN as solvent there are discrepancies. Attempts to prepare electrodes of the second kind having const. potentials in contact with solutions in  $COMe_2$ , MeCN, and  $C_5H_5N$  were unsuccessful. For NaCl solutions in MeOH, the relation between  $f$  and  $c$ , derived from concn. cell measurements, deviates at the highest dilutions from the Debye-Hückel theory. R. C.

**Phenomenon of induced dissolution of metals in solutions of neutral salts.** V. G. ZAPROMETOV (Bull. Univ. Asié Centrale, 1935, No. 21, 39—47).—The potential developed at a Pb plate in aq.  $CuSO_4$  at  $19^\circ$  has a max. val. for 0.07—0.1% solutions. Pptn. of  $PbSO_4$  from the solution is observed before deposition of Cu on the Pb; analogous results are obtained when  $K_2SO_4$ ,  $(NH_4)_2SO_4$ , or  $NiSO_4$  is substituted for  $CuSO_4$ , and when Cu is immersed in aq. KCNS,  $NH_4CNS$ ,  $Fe(CNS)_3$ ,  $Co(CNS)_2$ , or KCl. The process is conveniently studied by observing the potential changes at a Pt anode placed in a solution containing Cu or Pb and different salts. The mechanism consists in ionisation of the metal and formation of insol. salts. R. T.

**Thermodynamic derivation of diffusion potentials in concentrated solutions.** Z. SZABÓ (Naturwiss., 1936, 24, 539—540).—The method is based on the determination of the e.m.f. of non-isothermal cells. This gives the ratio of the ionic activities, from which the difference of electrode potentials may be calc. From this and the e.m.f. of the concn. cell with transport, the diffusion potential can be calc. A. J. M.

**Reduction-oxidation potential of flavins.**—See this vol., 1127.

**Oxidation-reduction potentials in non-aqueous solutions. II.** J. R. PARTINGTON and J. W. SKEEN (Trans. Faraday Soc., 1936, 32, 975—989; cf. A., 1935, 38).—E.m.f. measurements have been made with cells of the type Pt|oxidised salt+reduced salt+non-aq. solvent|reference electrode. Data are given for  $Cu(CNS)_2$ -CuCNS in  $C_5H_5N$ ,  $CuCl_2$ -CuCl in MeCN,  $FeCl_3$ -FeCl $_2$  in  $COMe_2$ , and  $Pb(OAc)_4$ -Pb(OAc) $_2$  in AcOH, and some results for other similar systems are given. Peters' formula can be applied quantitatively to several of these systems. In some cases unknown complexes are probably formed giving reproducible potentials which do not agree with the equation. In others indefinite potentials are indicated. O. J. W.

**Oxidation-reduction. XXII. Lapachol, lomatiol, and related compounds.** E. G. BALL (J. Biol. Chem., 1936, 114, 649—655).—The vals. of  $E'_0$  for lapachol, lomatiol, and a no. of synthetic 3-hydroxy-

2-alkyl-1:4-naphthaquinones at  $p_H$  1.1—12.6 are tabulated, together with the vals. of  $E_0$ ,  $p_{K_1}$ , and  $p_{K_2}$  at 30°. None of the compounds presents any advantages over phthiocol as an oxidation-reduction indicator. H. D.

**Influence of pressure on potential in relation to the depolarising effect of dissolved gases in the electrolysis of water.** III. V. SCHISCHKIN, J. DUBKOV, and E. KRASNOPOLSKAJA (Z. Elektrochem., 1936, 42, 631—635; cf. A., 1934, 1178).—Apparatus for the electrolysis of  $H_2O$  at pressures up to 200 kg. per sq. cm. is described. The change of p.d. with pressure is small and can be accounted for by the depolarising influence of dissolved gases. E. S. H.

**Polarographic investigations of anhydrous acetic acid solutions.** D. MACGILLAVRY (Trans. Faraday Soc., 1936, 32, 1447—1450).—Features of polarograms obtained with the dropping Hg cathode are compared with those for aq. solutions. With electrolytes in AcOH no breaks characteristic of the ions in solution are obtained and the presence of  $O_2$  does not cause max. E. S. H.

**Platinum electrode. I. Capacity of platinised platinum in different electrolytes and electro-motive behaviour of adsorbed hydrogen.** A. SEHLIGIN and A. FRUMKIN (Acta Physicochim. U.R.S.S., 1935, 3, 791—818; cf. A., 1934, 846).—The relation between the electrode potential  $\phi$  and the quantity of electricity  $Q$  passed has been studied with a large electrode surface and small c.d. The slope of the  $\phi$ - $Q$  curve is at first small (desorption of the adsorbed H), then becomes steeper (formation of the double layer), and finally decreases with the onset of oxidation. The H adsorption depends on the nature of the electrolyte, increasing in the order HBr, HCl,  $H_2SO_4$ , KOH. When the polarising current is interrupted,  $\phi$  remains const. or decreases slowly. If the polarising current is reversed in the "double layer region" hysteresis occurs which varies with the nature of the electrolyte.  $Q$  increases in the ratio 1:1.35 when the c.d. decreases from  $4.5 \times 10^{-4}$  to  $4.5 \times 10^{-6}$  amp. per sq. cm. There is a linear relation between the amount of adsorbed H, taken from the initial region of the  $\phi$ - $Q$  curve, and  $\log p_H$ . The results are discussed in relation to the nature of the adsorbed H layer. R. S.

**Cathode polarisation as a function of the current density in fused salts.** S. KARPATSOV and O. POLTORATSKA (J. Physical Chem., 1936, 40, 763—768).—The polarisation at C electrodes in fused  $PbCl_2$  and  $CdCl_2$  has been studied. The variation of the cathode potential ( $E$ ) with c.d. ( $i$ ) in the region of positive vals. of the potential is attributable to the slowness of diffusion of Pb or Cd atoms from the cathode into the fused electrolyte. For negative vals. of the potential,  $E = a - (RT/2F) \log i$ , where  $a$  is a const. J. W. S.

**Poisoning phenomena and hydrogen over-voltage.** M. G. RAEDER and K. W. NILSEN (Norges Tek. Hiskole Avh. til 25 Ars Jubileet, 1935, 263—279; Chem. Zentr., 1935, ii, 3640—3641).—In the electrolytic evolution of H, the active surface of the cathode plays the same rôle as in heterogeneous

catalysis. Evolution of H is considered to proceed preferentially at those points where the energy barrier between hydrated ions and neutral  $H_2$  mols. is lowest; these spots are occupied preferentially in the deposition of poisoning metals (e.g., Hg, As), thereby raising the val. of the energy barrier, and hence the overvoltage. J. S. A.

**Voltage-current curves obtained with an electrolytic cell and electric oscillations.** T. TERADA (Mem. Coll. Sci. Kyoto, 1936, A, 19, 57—64).—Curves for the p.d.-c.d. relation in a cell consisting of a Pt electrode in aq. HCl and a Pt wire which completes the circuit by touching the surface of the aq. HCl have been obtained. Definite stages in the curves are recognised and discussed. Electrical oscillations are produced. E. S. H.

**Anodic behaviour of gold-copper alloys in 5N-hydrochloric acid and 1N-sulphuric acid.** W. J. MULLER, H. FREISSLER, and E. PLETTERINGER (Z. Elektrochem., 1936, 42, 366—371).—In 5N-HCl all the Au-Cu alloys (0—100% Au) dissolve anodically at a c.d. of 2 amp. per sq. dm. without any passivity phenomena. From 100 to 50 at.-% Au the proportion of the two metals dissolved is the same as that present in the alloy. Between 50 and 30% Au the proportion of Cu dissolved increases, and below 30 at.-% Au only Cu goes into solution. In 1N- $H_2SO_4$  the alloys show passivity phenomena, and no Au is dissolved from any of the alloys. Cu is dissolved readily only up to 10 at.-% Au, and only in traces above 40 at.-% Au. O. J. W.

**Mechanism of electrolytic processes. III. Irreversible reductions.** W. M. LESLIE and J. A. V. BUTLER (Trans. Faraday Soc., 1936, 32, 989—998).—The mechanism of electrolytic reduction is discussed with special reference to the following examples, for which new measurements are recorded.  $COMe_2$ ,  $HCO_2Na$ , and  $C_5H_5N$  at Pb electrodes cause no significant displacement of the H overvoltage curve over the whole range, and these substances are reduced by free at. H.  $PhNO_2$  and  $PhCHO$  are reduced at a Hg electrode at more positive potentials than those at which H is liberated in their absence. These reductions are probably effected by direct transfer of electrons from the electrode, although reduction by absorbed H, liberated below the normal overvoltage, cannot be definitely excluded. In the reduction of  $C_5H_5N$  with a Pt electrode the H overvoltage is displaced in the negative direction; this is due to the adsorption of the substance on the electrode. O. J. W.

**Dimethylglycine buffer.** L. MICHAELIS and M. P. SCHUBERT (J. Biol. Chem., 1936, 115, 221—222).—The prep. of  $NMe_2 \cdot CH_2 \cdot CO_2Na$  (I) for use as a buffer in the range  $p_H$  8.6—9.6 is described and the  $p_H$  of (I)-HCl mixtures tabulated. H. D.

**Classifications of chemical reactions.** N. M. GOPSTEIN (Acta Physicochim. U.R.S.S., 1935, 3, 975—976).—A new derivation of Balandin's equation (cf. A., 1935, 1348) is given. R. S.

**Reaction isotherm and its deduction by means of the equilibrium box.** A. BANCHEFFI (Gazzetta, 1936, 66, 370—374).—A discussion of the methods

used in various text-books of physical chemistry to derive the max. work of a chemical reaction.

O. J. W.

**Kinetics of explosive reactions.** C. N. HINSHELWOOD (Z. Elektrochem., 1936, 42, 445—449).—A lecture.

E. S. H.

**Combustion processes and explosions in the gaseous phase.** M. BODENSTEIN (Z. Elektrochem., 1936, 42, 439—445).—A lecture.

E. S. H.

**Optical investigations on flames.** K. F. BONHOEFFER (Z. Elektrochem., 1936, 42, 449—457).—A lecture describing published work on hydrocarbon,  $H_2$ , and CO flames.

E. S. H.

**Ignition and flame propagation.** W. JOST (Z. Elektrochem., 1936, 42, 461—467).—Published work is discussed.

E. S. H.

**Flames of light and heavy hydrogen.** K. CLUSIUS and H. GUTSCHMIDT (Z. Elektrochem., 1936, 42, 498).—The effect of convection on the propagation of combustion of  $H_2$  and  $D_2$  in  $O_2$  with and without inert gases ( $N_2$ , He, A, Ne) is demonstrated.

E. S. H.

**Detonation.** R. BECKER (Z. Elektrochem., 1936, 42, 457—461).—A lecture on the characteristics of detonation and combustion in gaseous mixtures.

E. S. H.

**Determination of explosion limits of chlorine-hydrogen mixtures.** A. WEISSWEILER (Z. Elektrochem., 1936, 42, 499—503).—The explosion limits, determined by a photographic method, lie between 6 and 84.5%  $H_2$ . At the lower limit the pressure curve shows a marked, superimposed detonation wave. A similar phenomenon has been observed in  $H_2$ - $O_2$  and  $H_2$ -air mixtures.

E. S. H.

**Spectrographic method of studying the thermal decomposition of ozone.** E. VASSY (Compt. rend., 1936, 203, 403—406).—The variation with temp. of the absorption coeff. of  $O_3$  has been determined quantitatively. A knowledge of this variation enables the concn. of  $O_3$  in a mixture to be determined spectrographically. The decomp. of  $O_3$  at  $115^\circ$  is at first bimol., but after about 10 hr. deviations from the bimol. equation occur owing to desorption of  $O_3$  from the walls of the containing vessel.

A. J. M.

**Homogeneous unimolecular decomposition of gaseous alkyl nitrites. VII. Effect of chemical configuration on the reaction rate.** E. W. R. STEACLE, S. KATZ, S. L. ROSENBERG, and W. McF. SMITH (Canad. J. Res., 1936, 14, B, 268—274).—The rate of decomp. of alkyl nitrites, which is determined by the primary reaction  $RO\cdot NO = RO + NO$ , is suitable for examining the effect of chemical constitution on reaction rate. The method of Kassel is used to derive expressions for the rate of reaction at high and low pressures, and the relative rates of reaction of members of an homologous series. The Kassel theory is in good agreement with experiment in the case of the alkyl nitrites, but does not explain why the rate of decomp. increases as the series is ascended. The factors determining this increase are considered.

A. J. M.

**Thermal decomposition of dioxan.** P. GROSS and H. SUESS (Monatsh., 1936, 68, 207—214).—The thermal decomp. of dioxan has been studied at  $459$ — $534^\circ$  and  $50$ — $600$  mm., the main reaction being  $C_4H_8O_2 = 2CO + C_2H_6 + H_2$ , accompanied by  $C_4H_8O_2 = 2CO + 2CH_4$ . The unimol. reaction coeff. ( $k$ ) is almost independent of surface/vol. ratio, and is given by  $k = 3.20 \times 10^7 e^{-37.650/RT} / [1 + 4.95 \times 10^{-6} e^{37.650/RT} / p]$  sec.<sup>-1</sup> ( $p$  in dynes per sq. cm.;  $R$  in g.-cal.). The departure from the simple theory of homogeneous gas reactions is perhaps due to the presence of two or more reactions. The decomp. of  $Me_2CO_3$  at  $450^\circ$  into  $H_2 + CO + CO_2 + CH_4$  at  $184$ — $244$  mm. is heterogeneous to a considerable extent; the reaction  $Me_2CO_3 + H_2O = 2MeOH + CO_2$  at  $305^\circ$  is almost entirely heterogeneous.

R. S. B.

**Pyrogenic condensation of hydrocarbons. V. Kinetics of polymerisation of hexanes.** M. S. NEMTZOV and A. V. POLETAEV (J. Gen. Chem. Russ., 1936, 6, 892—897).—The energy of activation of the reaction of polymerisation of  $\Delta^3$ - $n$ -hexene (I) at  $350$ — $400^\circ$  is  $38,000 \pm 1000$ , and the velocity coeff. is given by  $\log k = 9.07 - 38,000/4.57T$ . The velocity of polymerisation of  $\gamma$ -methyl- $\Delta^3$ -pentene (II) is half as great as that of (I). The products are chiefly the di- and tri-merides. (I) is more stable than (II).

R. T.

**Kinetics of the thermal decomposition of alkylene oxides. I. Ethylene oxide.** H. W. THOMPSON and M. MEISSNER (Trans. Faraday Soc., 1936, 32, 1451—1460).—The reaction products are mainly  $CH_4$  and CO. The reaction is approx. first order. The unimol. velocity coeff. falls with decreasing initial pressure in the same way as in other quasi-unimol. decomp., and the plot of  $k$  against the initial pressure has a segmented appearance. The reaction is homogeneous; there is no evidence of the propagation of reaction chains. The energy of activation at the higher pressures is about  $53,000$  g.-cal., falling slightly as the initial pressure is lowered.

E. S. H.

**Influence of temperature on inflammation limits of combustible vapours in air.**—See B., 1936, 728.

**Upper temperature limit of explosion of explosives.**—See B., 1936, 910.

**Gaseous explosions. Critical initial temperature for maximum rate of pressure rise.** W. A. PEARL and G. G. BROWN (Ind. Eng. Chem., 1936, 28, 1058—1065).—Bomb experiments indicate that the crit. initial temp. ( $T'$ ), at which the rate of pressure rise on explosion is a max., depends on the composition of the products of combustion and the diluents. Explosive mixtures giving products having heat capacities with low temp. coeffs. are characterised by high  $T'$ , and the greater is the C : H ratio of the fuel, the lower is  $T'$ . In all cases, increasing the diluent, or excess of  $O_2$  or fuel, raises  $T'$ , whilst increasing the excess of  $H_2$  fuel raises  $T'$  relatively much < increasing the hydrocarbon fuel.  $T'$  under conditions of const. initial pressure is < at const. initial  $d$  for both theoretical and near theoretical mixtures containing small concns. of diluent  $N_2$ . For mixtures containing concns. of diluent  $N_2$  < that of

air,  $T$  at const. initial pressure is  $>$  at const. initial  $d$ . Similar relations are found in gasoline engine tests.

H. C. M.

**Mechanism of hydrocarbon combustion.** A. R. UBBELOHDE (Z. Elektrochem., 1936, 42, 468—471).—A lecture.

E. S. H.

**Induction time and ignition temperature of methane-oxygen mixtures.** H. SACHSSE (Z. Elektrochem., 1936, 42, 504).—The induction period, when  $\text{CH}_4$  and  $\text{O}_2$  (2 : 1) are passed through a quartz tube at 850—950°, has been measured. A chain mechanism is proposed.

E. S. H.

**Mechanism of oxidation of hydrocarbons.** W. JOST, L. (FRHR.) VON MUFFLING, and W. ROHRMANN (Z. Elektrochem., 1936, 42, 488—497).—Mainly a discussion of published work. Experiments on the oxidation of paraffins, naphthenes, and olefines are described. The results support earlier work. There are sharp pressure limits of explosion at const. temp., and at certain compositions wide temp. ranges in which explosion does not occur. The action of anti-knock agents is discussed.

E. S. H.

**Explosive oxidation of methane.** N. KOBOSOV, J. KASARNOVSKI, and L. KASHTANOV (Acta Physicochim. U.R.S.S., 1935, 3, 857—878).—The yield of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CO}$ , and  $\text{H}_2$  per cu.m. of  $\text{CH}_4$  consumed in an equimol. mixture of  $\text{CH}_4$  and  $\text{O}_2$  is independent of pressure up to 3.70 atm. and is unaffected by the nature of the wall or the diameter of the vessel, although the amount of  $\text{CH}_4$  oxidised is less in narrow vessels. The influence of additions of  $\text{N}_2$ ,  $\text{CO}$ ,  $\text{CO}_2$ , and  $\text{H}_2$  is in agreement with thermodynamic requirements. The explosion temp. calc. from the water-gas equilibrium data agrees closely with that calc. from sp. heat data, and it is inferred that equilibrium is attained in the explosion. If  $\text{H}_2\text{O}$  is present initially  $\text{CH}_2\text{O}$  and  $\text{EtOH}$  are formed and equilibrium is not attained. The reaction forms a suitable source of  $\text{H}_2$  for the  $\text{NH}_3$  synthesis.

R. S.

**Synthesis of hydrogen sulphide.** D. PORRET (Helv. Chim. Acta., 1936, 19, 680—694).—The reaction between  $\text{H}_2$  and  $\text{S}$  has been studied at 307° and 343° by a static method and at 450° and 500° by a dynamic method. At the lower temp. the rate  $\propto [\text{H}_2][\text{S}]^{\frac{1}{2}}$ . In this temp. range  $[\text{S}_2]$  is also  $\propto [\text{total S}]^{\frac{1}{2}}$ . At the higher temp. both  $\text{S}_8$  and  $\text{S}_2$  may react with  $\text{H}_2$ . The rate is  $>$  that calc. from the activation energy (52,000 g.-cal.). The reaction is not a normal bimol. reaction and may involve chains initiated by a process such as  $\text{H}_2 + \text{S}_2 = \text{H}_2\text{S} + \text{S}$ , or heterogeneously.

H. J. E.

**Theory of electrokinetic effects in solution; reactions between ions.** E. A. MOELWYN-HUGHES (Proc. Roy. Soc., 1936, A, 155, 308—315).—Bimol. reactions in solutions have normal velocity when  $k = Ze^{-E_A/RT}$ .  $E_A$  is the energy of activation (Arrhenius) and  $Z$  is a theoretical collision frequency. The abnormality in the reaction rate is determined by the term  $P$  in  $k = PZe^{-E_A/RT}$ . The abs. magnitude of the velocity is considered, and attempts are made to interpret the experimental vals. of  $P$  as high as  $10^8$  and as low as  $10^7$ . The deviation from normal behaviour is attributed to electrostatic

attraction. Debye and Huckel's expression is introduced and theoretical equations are obtained for  $P$  and the variation of  $E_A$  with temp. and ionic strength.

L. L. B.

**Influence of the solvent on the kinetics of bimolecular reactions in solutions.** B. I. SVESHNIKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 61—65).—Theoretical. The influence of viscosity on the velocity coeff. is related to the mean life of the activated state.

R. S.

**Interaction of sodium formate and sodium hydroxide.** A. A. BALANDIN and L. C. FREIDLIN (J. Gen. Chem. Russ., 1936, 6, 868—872).—The reaction between  $\text{HCO}_2\text{Na}$  (I) and  $\text{NaOH}$  commences at 210°, and proceeds at high velocity at 250°. In presence of the theoretical amount of  $\text{NaOH}$  it is represented as  $(\text{I}) + \text{NaOH} \rightarrow \text{Na}_2\text{CO}_3 + \text{H}_2$ , whilst in presence of excess of (I), and at  $>270^\circ$ , the reaction  $2(\text{I}) \rightarrow \text{Na}_2\text{C}_2\text{O}_4$  (II) +  $\text{H}_2$  takes place. (II) also reacts at  $>260^\circ$  as follows:  $(\text{II}) + 2\text{NaOH} \rightarrow 2\text{Na}_2\text{CO}_3 + \text{H}_2$ .

R. T.

**Kinetics of the oxidation of formic acid by iodic acid.** E. ABEL and A. BILDERMANN (Monatsh., 1936, 68, 215—232).—The reaction  $5\text{HCO}_2\text{H} + 2\text{HIO}_3 = \text{I}_2 + 5\text{CO}_2 + 6\text{H}_2\text{O}$  has been studied at 60°. I is an inductor owing to the reaction  $\text{I}_2 + \text{HCO}_2\text{H} = \text{CO}_2 + 2\text{HI}$  (a), followed by  $\text{HIO}_3 + 5\text{HI} = 3\text{I}_2 + 3\text{H}_2\text{O}$  (b). For (a)  $d(\text{CO}_2)/dt = 1.0 \times 10^2 [\text{I}_2][\text{HCO}_2\text{H}]$ , where  $t$  is in min. and concn. in mol. per litre.  $\text{HOI}$  formed by hydrolysis of I reacts  $(\text{HOI} + \text{HCO}_2\text{H} = \text{CO}_2 + \text{H}_2\text{O} + \text{HI})$  according to  $d(\text{CO}_2)/dt = 5.7 \times 10^2 [\text{HOI}][\text{HCO}_2\text{H}]\{1 + 5.7[\text{HCO}_2\text{H}]\}$ . The reaction between  $\text{HCO}_2\text{H}$  and  $\text{HIO}_3$  is expressed as a function of the subsidiary reactions, and is compared with the reaction between  $\text{HIO}_3$  and  $\text{H}_2\text{C}_2\text{O}_4$  (cf. A., 1935, 587).

R. S. B.

**Kinetics of saponifications of iodoacetic acid by sodium hydroxide and by certain alkaline buffer solutions.** R. BRDIČKA (J. Gen. Physiol., 1936, 19, 899—906).—The bimol. velocity coeffs. of the rate of hydrolysis of iodoacetic acid increase with the ionic strength of the solution. In borate buffer solutions, the reaction is unimol.; at  $>11.2$  the coeffs.  $\propto [\text{OH}^-]$ , and at  $p_H < 11.2$  they  $\propto [\text{borate}]$ .

F. A. A.

**Mechanism of thermal poly-condensation reactions.** H. DOSTAL and R. RAFF (Monatsh., 1936, 68, 188—201, 247—250).—(A) The general theory of poly-condensations is discussed and is applied to the reactions between succinic acid (I) and  $(\text{CH}_2\text{OH})_2$  (II) and  $(\text{C}_2\text{H}_4\text{OH})_2$  at 110—150° in dioxan. The relative quantity of condensation =  $1 - (1 + at/2)^{-2}$ , where  $a$  is a reaction coeff.; there is no induction period. The reaction velocity for (II) varies for the first 10 hr. with approx. the second power of the concn., and then with a lower power. The temp. coeff. and influence of medium are discussed.

(B) The reaction between (I) and (II) has been further studied, leading to a revised val. of the activation energy. The influence of the solvent is small.

R. S. B.

**Thermal mutarotation of *d*-galactose, *l*-arabinose, and *d*-talose.** H. S. ISBELL and W. W.

PIGMAN (J. Res. Nat. Bur. Stand., 1936, 16, 553—554).—Aq. solutions of galactose (I), arabinose (II), and talose (III) were cooled rapidly from 25° to 0° and the change with time of  $\alpha$  was observed. The thermal mutarotation consists of (a) a rapid change due to a change in concn. of the labile constituents, and (b) a slow change due to a disturbance in the equilibrium of  $\alpha$ - and  $\beta$ -isomerides. The heats of activation for the reactions (a) and (b) for (I), (II), and (III) are respectively (a) 15,040, 14,700, and 12,750; (b) 17,130, 16,800, and 15,820 g.-cal. per g.-mol. The ordinary mutarotations of (I) and (II) are in agreement with published vals. For  $\alpha$ -d-talose (previously undetermined)  $[\alpha]^{20} = 9.3 \times 10^{-0.0263t} + 37.9 \times 10^{-0.126t} + 20.8$ ;  $[\alpha]_D^{25} = 9.8 \times 10^{-0.00362t} + 27.5 \times 10^{-0.0255t} + 25.2$ , where  $t$ —time. R. S. B.

**Specificity of salt effect in some ionic reactions.** L. SMITH [with B. OLIN] (Z. physikal. Chem., 1936, 177, 131—157).—The rates of hydrolysis at 25° by NaOH, Ca(OH)<sub>2</sub>, Sr(OH)<sub>2</sub>, and Ba(OH)<sub>2</sub> of chloro-substituted hydroxycarboxylic acids, acetyl- and benzoyl-citric acids, and bromotricarballic acid have been determined, the acid anion (I) and OH<sup>-</sup> being in equiv. concns. of 0.004—0.03M; the chloride or nitrate of the base was present in some cases. The Bronsted-Debye-Hückel equation  $\log(k/k_0) = z_A z_B \sqrt{\mu}$ , where  $k$  is the bimol. velocity coeff. in a medium of ionic strength  $\mu$ , and  $z_A, z_B$  are valencies, is not, in general, valid. This discrepancy is partly due to the salt action being affected by the constitution of (I) and the sp. properties of the metal ion, and complex formation may also play some part. Dibasic acids exhibit greater ionic effects than monobasic acids, and in some cases configuration plays a part. In some reactions Na<sup>+</sup> ions have a negative salt effect, whilst bivalent ions have a normal positive effect. The temp. coeffs. of some of the reactions have been measured. The dissociation consts. of some of the acids have been determined from conductivity measurements. R. C.

**Kinetics of decomposition of the  $\gamma$ -bromobutyrate ion in neutral and in alkaline solution.** E. F. CALDIN and J. H. WOLFENDEN (J.C.S., 1936, 1239—1241).—The decomp. of Na  $\gamma$ -bromobutyrate in neutral and NaOH solutions has been investigated at 0—25° by conductivity measurements. In neutral solution, lactonisation takes place, not by a pseudo-unimol. mechanism involving collisions with solvent mols., but by a truly unimol. ionisation process of which the heat of activation is 32,500 g.-cal. and the velocity requires  $\approx 7$  internal degrees of freedom of the mol. In alkaline solution, lactonisation is followed by a bimol. reaction of the lactone with OH<sup>-</sup>. The temp. coeff. of the bimol. reaction leads to a heat of activation of 6450 g.-cal. and a  $P$ -factor of  $10^{-7}$ . J. G. A. G.

**Hydrolysis of monochloroacetate ion in light and heavy water.** O. RETZ (Z. physikal. Chem., 1936, 177, 85—94).—Hydrolysis by OH<sup>-</sup> is about 20% more rapid in D<sub>2</sub>O than in H<sub>2</sub>O. In acid and neutral solution both CH<sub>3</sub>Cl·CO<sub>2</sub><sup>-</sup> (I) + H<sub>2</sub>O  $\rightarrow$  OH·CH<sub>2</sub>·CO<sub>2</sub>H (II) + Cl<sup>-</sup> and 2(I) CH<sub>2</sub>Cl·CO<sub>2</sub>·CH<sub>2</sub>CO<sub>2</sub><sup>-</sup> (III) + Cl<sup>-</sup>; (III) + H<sub>2</sub>O  $\rightarrow$  (II) + (I) are retarded in D<sub>2</sub>O by about 8%. This retard.

ation is probably purely a solvent effect and not directly connected with the reaction mechanism. R. C.

**Hydration rate of methylethylethylene [ $\beta$ -methyl- $\Delta^2$ -butene] in aqueous solutions of acids.** Y. P. LIU and T. C. WEI (J. Chinese Chem. Soc., 1936, 4, 297—304; cf. A., 1934, 1312).—The rate of hydration of CH<sub>2</sub>:CMeEt to CMe<sub>2</sub>Et·OH by dil. HNO<sub>3</sub> at 25° and 35° and const. ionic strength is unimol. with respect to each reactant. At const. [HNO<sub>3</sub>], the rate is increased by adding KNO<sub>3</sub>. The temp. coeff. is 3.21 corresponding with the energy of activation 21.04 kg.-cal. The rate of hydration of the olefines is in the order isobutene > CH<sub>2</sub>:CMeEt > CHMe:CMe<sub>2</sub>, probably owing to steric effects. The catalytic effect of 0.1M-acids on the hydration of CH<sub>2</sub>:CMeEt at 25° is in the order H<sub>2</sub>SO<sub>4</sub> > HCl > HClO<sub>4</sub> > HBr > HNO<sub>3</sub> > C<sub>6</sub>H<sub>5</sub>Me·SO<sub>3</sub>H > H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> > AcOH. J. G. A. G.

**Application of the chain theory of chemical change to certain enzyme reactions.**—See this vol., 1296.

**Kinetics of reaction between -SH groups and iodoacetic acid.**—See this vol., 1291.

**Kinetics of polymerisation and poly-condensation reactions.** H. MARK (Chem. Weekblad, 1936, 33, 514—515).—A lecture. S. C.

**Application of Hahn's emanation method to investigation of reactions in solid state.** III. R. JAGITSCH (Z. physikal. Chem., 1936, B, 33, 196—200).—For the formation of PbSiO<sub>3</sub> from PbO and SiO<sub>2</sub> at 500—700°, followed by the above method, the unimol. law is valid. At 500—640° the velocity coeff.,  $k$ , is at first determined by the rate of diffusion of the PbO to the SiO<sub>2</sub>, but after a time abruptly assumes a lower val., being now determined by the rate of diffusion of the PbO through the PbSiO<sub>3</sub>. At 700°, however,  $k$  remains const. throughout, being determined by the rate of diffusion of the PbO to the SiO<sub>2</sub>. R. C.

**Corrosion.**—See B., 1936, 743, 744.

**Theories of corrosion. II. Distribution of corrosion.** J. E. O. MAYNE (J.C.S., 1936, 1095—1098).—The distribution of corrosion of rectangular steel specimens partly immersed in 0.1N-KCl departs progressively from Evans' "ideal distribution" as the thickness is increased, until, with specimens of square cross-section, there is no preferential corrosion at the edges, consistent with the distribution of corrosion being governed by alkali distribution. The corrosion of a composite steel plate of two laminæ separated by insulating material, partly immersed at an angle of 45° in 0.1N-KCl, follows Evans' "ideal distribution," but the attack on the upper surface is > on the lower. When the aq. KCl contains 0.1 of the saturation val. of CO<sub>2</sub>, the distribution of corrosion of the upper surface is not affected, but the whole of the lower surface is attacked, indicating that the alkali concn. at the upper surface is > at the lower surface, and supporting the view that total O<sub>2</sub> supply governs the amount of corrosion. J. G. A. G.

**Reactions of atomic oxygen with halogen salts of mercury.** S. ROGINSKI and A. SCHECHTER (Acta

Physicochim. U.R.S.S., 1935, 3, 219—222).—At. O reacts with  $\text{HgX}_2$  ( $\text{X}=\text{Cl}, \text{Br}, \text{I}$ ), more readily at 200—300°. The heats of activation for  $\text{HgCl}_2$  and  $\text{HgI}_2$  are approx. 3000 and 6000 kg.-cal., respectively. All the reactions are accompanied by a sharp and intense fluorescence. O. J. W.

**Dissolution of magnesium oxide in magnesium sulphate solutions.** (MLLE.) M. L. DELYON (Bull. Soc. chim., 1936, [v], 3, 1632—1638).—The curve relating amount dissolved with time for  $\text{MgO}$  in aq.  $\text{MgSO}_4$  shows a regular initial increase to a max. val., a period during which little or no further dissolution occurs, and then a period of pptn. of oxysulphate. The solubility, defined by the max. amount of  $\text{MgO}$  absorbed,  $\propto$  the  $[\text{MgSO}_4]$ . Rise in temp. increases the solubility and accelerates the formation of oxysulphate. Optimum conditions for the production of the latter are deduced. J. W. S.

**Attack of aluminium by chlorine.** I. M. G. EVANS (Mem. Manchester Phil. Soc., 1934—1935, 79, 13—28).—The velocity of attack of Al foil by  $\text{Cl}_2$  at 134—254° and 100—600 mm. is independent of the pressure and has an apparent energy of activation of 2000 g.-cal. During attack large crystals of Al are broken up and the X-ray powder photograph becomes sharper. The kinetics of the reaction are discussed. R. S. B.

**Mechanism of combustion of graphite at different temperatures.** II. V. N. PERTZOV and M. C. KARAPETJANTZ (J. Appl. Chem. Russ., 1936, 9, 1269—1277).—The reaction  $\text{C} + \text{O} \rightarrow \text{CO}_2$  proceeds at low velocity at <600°; at >600° the C is surrounded by a zone of burning CO, as a result of which the  $[\text{O}_2]$  of the atm. in contact with the C falls, and the velocity of combustion of the C correspondingly diminishes. A second break is observed at 800—850°, at which  $\text{O}_2$  is entirely absent from the atm. surrounding the C, the reaction taking place at the surface being  $\text{CO}_2 + \text{C} \rightarrow 2\text{CO}$ . R. T.

**Kinetics and heat of adsorption of ethylene by platinum.** E. B. MAXTED and C. H. MOON (Trans. Faraday Soc., 1936, 32, 1375—1381).—In the slow secondary adsorption that follows the immediate primary process, the ratio of the vol. adsorbed to the square root of the time is const. The mol. heat of adsorption of  $\text{C}_2\text{H}_4$  by Pt is 9 kg.-cal. E. S. H.

**Rate of dissolution of paraformaldehyde.**—See this vol., 1232.

**Induced and catalysed reactions.** F. FEIGL (Oesterr. Chem.-Ztg., 1936, 39, 139—140).—A lecture.

**Causes of decomposition of hydrogen peroxide, and the stabilisation of perhydrol.**—See B., 1936, 884.

**Effect of nitrate ions on the systems  $\text{Zn}^\circ/\text{Ni}^{+++}$  in water and  $\text{Zn}^\circ/\text{Ni}^\circ$  in water.** A. OLIVERIO and O. BELFIORI (Rend. sem. fac. sci. Univ. Cagliari, 1933, 3, 51—55).—Traces of  $\text{NO}_3^-$  retard the pptn. of Ni from its salts by Zn and also the reaction  $\text{Zn} + 2\text{H}^+ \rightarrow \text{Zn}^{++} + \text{H}_2$ . Large amounts of  $\text{NO}_3^-$  lead to the formation of basic Zn and Ni salts. The passive effect produced by  $\text{NO}_3^-$  is due to the ion itself and not to its reduction products ( $\text{NO}_2^-$ ,  $\text{NH}_4^+$ ).

CH. ABS. (e)

**Stabilisation of diazo-compounds in solution.**—See B., 1936, 779.

**Mechanism of autoxidation of hydrocarbons in the liquid phase.** M. N. MICHAILOVA and M. B. NEIMAN (J. Gen. Chem. Russ., 1936, 6, 821—838).—The velocity of oxidation  $v$  of cracking benzene  $\propto$  partial  $\text{O}_2$  pressure, temp., and liquid-gas interface, and inversely  $\propto$  concn. of inhibitor ( $\alpha\text{-C}_{10}\text{H}_7\text{OH}$ ). The length of the induction period  $\propto 1/v$ , and is smaller in presence than in absence of light, active centres being formed only at the surface in the latter case, and also in the bulk of the liquid in the former. The action of inhibitors consists in interrupting oxidative chain reactions taking place in the bulk of the liquid. Oxidation does not take place in the gaseous phase at low temp. R. T.

**Ascorbic acid as catalyst in oxidation of unsaturated fats.**—See this vol., 1303.

**Induction effect of ascorbic acid on oxidation of sugar.**—See this vol., 1304.

**Contact question as an equilibrium problem.** R. SCHENCK (Angew. Chem., 1936, 49, 649—653).—The sp. characteristics of mixed catalysts, and the action of promoters, are related to the influence of solid reactions on the heterogeneous equilibria obtaining between the catalyst and a gaseous component. Thus with mixtures of oxides, addition of an oxide capable of mixed crystal or compound (e.g., spinel) formation considerably affects the equilibrium  $\text{O}_2$  pressure of the system (cf. A., 1930, 43). Similar effects in reduction reactions are shown by the equilibrium  $\text{H}_2\text{S}-\text{H}_2$  ratio over  $\text{Cu}_2\text{S}-\text{Sb}_2\text{S}_3$  or  $\text{PbS}-\text{Sb}_2\text{S}_3$  mixtures, and by the  $\text{CH}_4-\text{H}_2$  ratio over Mn-Cu alloys. J. S. A.

**Stable platinum alloys as catalysts of oxidation of ammonia.**—See B., 1936, 832.

**Surface reactions at very low pressures.** III. **Platinum-iodine.** C. NOGAREDA (Anal. Fis. Quím., 1934, 32, 658—665; cf. A., 1935, 711, 941).—A Pt wire is attacked by I atoms at 1200—1350°, affording  $\text{PtI}_2$ . The reaction is strongly endothermic, of zero order, and in accordance with a mechanism of limiting adsorption. A sublimated Pt layer adsorbs at 0° a limiting unimol. I film, stable to about 100°. A reduced Pt layer adsorbs only about half this amount of I. A simultaneous attack by I atoms on the wire and on the reduced Pt layers has been observed above 1200°. L. A. O'N.

**Evolution of sulphur dioxide and trioxide from calcium sulphate treated with chlorine in presence of a catalyst.** P. P. BUDNIKOV and E. I. KRETSCH (J. Appl. Chem. Russ., 1936, 9, 995—1009).—Decomp. of  $\text{CaSO}_4$  in presence of  $\text{Cl}_2$  commences at 800—850° in absence, and at 700—750° in presence, of  $\text{NaCl}$ ,  $\text{Na}_2\text{SO}_4$ , or  $\text{SiO}_2$ . The activity of catalysts at 900—950° falls in the order  $\text{NiSO}_4 > \text{CuSO}_4 > \text{MnCl}_2 > \text{MnO}_2 > \text{MgSO}_4 > \text{Fe}_2\text{O}_3 > \text{KCl}$ . Decomp. commences at 450—500° for 4 : 1 C- $\text{CaSO}_4$  mixtures, and is completed after 1 hr. at 700°. Addition of steam to the  $\text{Cl}_2$  has no effect on the reaction. Max. velocity of decomp. is found for 1 : 4 mol.  $\text{CaSO}_4$ - $\text{SiO}_2$  mixtures, the best effect being given by amorphous  $\text{SiO}_2$ .

R. T.

**Vanadium catalysts for sulphuric acid production.**—See B., 1936, 737.

**Amorphous and crystalline oxide hydrates and oxides. XXVII. Catalytic decomposition of hydrogen peroxide and the "active positions" of the amorphous ferric hydroxides and the products of their ageing.** A. KRAUSE [with D. KANIOWSKA] (Ber., 1936, 69, [B], 1982—1990; cf. this vol., 947).—The roentgenographically amorphous ortho-Fe<sup>III</sup> hydroxides (I) decompose H<sub>2</sub>O<sub>2</sub> fairly rapidly, the change being of the first order. Slowly and rapidly ageing, non-ageing, freshly prepared, and aged specimens are equally active because they all readily unite with Ag. H replaceable by Ag in the ortho-hydroxides must be regarded as active in Wieland's sense; H<sub>2</sub>O<sub>2</sub> can therefore cause dehydrogenation whereby it becomes decomposed. The chemistry of the process which involves the intermediate production of a labile Fe<sup>III</sup> peroxide is discussed. When suitable treatment causes (I) to lose its power of uniting with Ag, the catalytic activity is very considerably diminished. The amorphous condition and the "ageing activity" are not related directly with the catalytic decomp. of H<sub>2</sub>O<sub>2</sub>. "Active positions" may also be present in cryst. Fe<sup>III</sup> hydroxides if the necessary OH contain H replaceable by Ag. A fresh, almost yellow product showing distinctly the interferences of goethite united readily with Ag and accelerated the decomp. of H<sub>2</sub>O<sub>2</sub>, but further ageing in *N*- and 0.5*N*-NaOH destroyed both types of activity. The product thus formed, (α-Fe<sub>2</sub>O<sub>3</sub>.H<sub>2</sub>O)<sub>n</sub>, is identical in these properties with Bohm's autoclaved material, from which it differs in apparent *d* and solubility in 1.4*N*-H<sub>2</sub>SO<sub>4</sub>. The use of C<sub>5</sub>H<sub>5</sub>N in the prep. of (I) appears to cause somewhat lessened activity. Decomp. of H<sub>2</sub>O<sub>2</sub> depends greatly on [H<sup>+</sup>] and proceeds most rapidly in alkaline solution. The increasingly intense decomp. of H<sub>2</sub>O<sub>2</sub> during the hydrolysis of Fe<sup>III</sup> salts is due to the production of basic salts the mols. of which are laden with OH groups. In addition to active positions of the "first rank" which must be regarded as identical with H atoms and cause marked decomp. of H<sub>2</sub>O<sub>2</sub>, there exist centres of the "second rank" which are probably related to the colloid-chemical properties of (I). H. W.

**Reaction zones in the reduction of magnetite and hæmatite with hydrogen.** G. TSCHUFAROV and E. TATIEVSKAJA (Acta Physicochim. U.R.S.S., 1935, 3, 957—974).—The reaction is autocatalytic. The change in porosity with temp. and degree of reduction has been studied and related to the reaction rate. Magnetite is less porous than hæmatite, but below 600° the rate of reduction is faster. Above this temp. the porosity and the rate of reduction decrease rapidly in both cases. Microscopical investigations show the presence of the layers α-Fe-Fe<sub>3</sub>O<sub>4</sub> in the case of magnetite, and α-Fe-Fe<sub>3</sub>O<sub>4</sub>-Fe<sub>2</sub>O<sub>3</sub> in the case of hæmatite, whilst FeO could not be detected, and it is suggested that Fe<sub>3</sub>O<sub>4</sub>→Fe is the rate-determining process. The rate of advance of the reduction zone is linear below 500°, and the activation energy for hæmatite is 15,700 g.-cal. R. S.

**Platinum electrode as a catalyst for the activation of hydrogen.** M. CALVIN (Trans. Fara-

day Soc., 1936, 32, 1428—1436).—The rate of the reaction D<sub>2</sub>+H<sub>2</sub>O→HD+HDO, catalysed by a Pt electrode in neutral and acid solutions, is reversibly retarded by small cathodic polarisations, but not increased by anodic polarisation up to 0.7 volt. Higher anodic polarisation inhibits the reaction irreversibly. The observations are discussed.

E. S. H.

**Thiol compounds as catalysts for the decomposition of sodium azide by iodine.** E. FRIEDMANN (J. pr. Chem., 1936, [ii], 146, 179—192).—Qual. and quant. study is made of the effect of 19 S compounds on the decomp. of NaN<sub>3</sub> by I. SH compounds cause much immediate decomp., linked with the reaction 2RSH→I<sub>2</sub>→R<sub>2</sub>S<sub>2</sub>+2HI, followed by a further slow decomp., linked with the reaction R<sub>2</sub>S<sub>2</sub>+5I<sub>2</sub>+6H<sub>2</sub>O→2RSO<sub>3</sub>H+10HI. Disulphides effect only the slower decomp. Sulphides are without action. CS(NH<sub>2</sub>)<sub>2</sub>, 4-methylthiohydantoin, and [NH<sub>2</sub>-C(NH)<sub>2</sub>-S]<sub>2</sub> cause the same violent decomp. as do SH compounds. The no. of mols. of NaN<sub>3</sub> decomposed varies greatly with the nature of the S compound, the ratio of the wts. of S compound and NaN<sub>3</sub>, and the concns. A chain mechanism is proposed. R. S. C.

**Catalytic reduction of carbon monoxide at ordinary pressures. VII. Influence of alkali content on the iron-copper catalyst.** S. KODAMA and K. FUJIMURA. **VIII. Influence of the proportions of the two metals in the iron-copper catalyst.** K. FUJIMURA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 272—279, 280—284; cf. B., 1935, 132).—VII. The reaction between CO and H<sub>2</sub> (1:2) has been studied at approx. 270° on an Fe-Cu (1:1) catalyst in presence of 0—0.05 mol. of Na<sub>2</sub>CO<sub>3</sub> per mol. of Fe. The Na<sub>2</sub>CO<sub>3</sub> increases the initial activity of the catalyst, but the rate of decrease in activity is > in the absence of Na<sub>2</sub>CO<sub>3</sub>. The Na<sub>2</sub>CO<sub>3</sub> increases the yield of hydrocarbons of high mol. wt.

**VIII.** The reaction between CO and H<sub>2</sub> (1:1) has been studied at approx. 270° on Fe-Cu catalysts (5:1, 3:1, and 1:2). The yield of benzene is unaffected by alteration in the Fe:Cu ratio, but the gas contraction is highest with the 1:2 catalyst.

R. S. B.

**New method of preparing catalysts.** L. FAUCONNAU (Compt. rend., 1936, 203, 406—407).—Cu and Co of high catalytic activity may be obtained from Devarda's alloy (Al-Cu-Zn) and Co<sub>2</sub>Al<sub>3</sub>, respectively, by repeated treatment with NaOH, washing with H<sub>2</sub>O and EtOH by decantation, and storing under EtOH. The catalysts will aid the dehydrogenation of primary and sec. alcohols. In the case of hydrogenations, the two catalysts give, in general, different results.

A. J. M.

**Catalytic action of copper oxide in the combustion of hydrogen. II.** G. TEDESCHI (Gazzetta, 1936, 66, 417—420; cf. this vol., 570).—Further experiments confirm the view that in the combustion of H<sub>2</sub>-O<sub>2</sub> mixtures the CuO acts as an O<sub>2</sub>-carrier.

O. J. W.

**Reduction of copper oxide and stannic oxide with Sarmasel natural gas.** C. CANDEA and J.

KÜHN (Petroleum, 1936, 32, No. 35, 11—14; cf. A., 1935, 592).—Reduction of CuO by natural gas (98.6% CH<sub>4</sub>) begins at 400° and is complete at 720°. Below 600° CH<sub>4</sub> is oxidised to CO<sub>2</sub> only, and very little H<sub>2</sub> is liberated. Above 600° CO appears and H<sub>2</sub> rises to 6.5%. C is deposited at all temp., its amount being independent of the degree of reduction  $r$ . Cu catalyses the decomp. of CH<sub>4</sub>, the H<sub>2</sub> formed then reducing CuO. Reduction of SnO<sub>2</sub> begins at 700°, and is complete at 910°;  $r$  is but little dependent on the rate of streaming of the CH<sub>4</sub>. Little C is deposited. The gases are low in H<sub>2</sub>, but contain unsaturated hydrocarbons (I). Sn has little catalytic effect on the CH<sub>4</sub> decomp., but promotes the formation of (I).

J. S. A.

**Catalytic interchange of hydrogen with water and alcohol.** D. D. ELEY and M. POLANYI (Trans. Faraday Soc., 1936, 32, 1388—1397).—The rate of the first step in the at. interchange in presence of Pt-black has been determined by the use of the para-H<sub>2</sub> conversion and the D<sub>2</sub>+H<sub>2</sub>=2HD reaction. The rate-determining step is the splitting of H<sub>2</sub>, which is influenced by the nature and acidity of the liquid. The products of dissociation of H<sub>2</sub> cannot be homopolar H atoms, but must be H<sup>+</sup> ions or H atoms in a strongly polarised state, e.g., participating in a Pt-H linking.

E. S. H.

**Activation of specific bonds in complex molecules at catalytic surfaces. I. Carbon-hydrogen linking in methane and methane-d<sub>4</sub>.** K. MORIKAWA, W. S. BENEDICT, and H. S. TAYLOR (J. Amer. Chem. Soc., 1936, 58, 1445—1449).—CH<sub>4</sub> undergoes exchange with D<sub>2</sub>, CD<sub>4</sub>, and D<sub>2</sub>O on active Ni catalysts at <138°. At 184° the rate of reaction with CH<sub>4</sub> decreases in the order CD<sub>4</sub>>D<sub>2</sub>>D<sub>2</sub>O. The activation energies of reaction with CD<sub>4</sub> and D<sub>2</sub> are ~19 and ~28 kg.-cal., respectively. The rate-determining step is ascribed to the activation of the C-H linking of CH<sub>4</sub>.

E. S. H.

**Reduction of carbon dioxide to higher hydrocarbons.**—See B., 1936, 727.

**Nitration of benzene.**—See B., 1936, 779.

**Activation of hydrogen by phthalocyanine and copper phthalocyanine. I.** M. CALVIN, E. G. COCKBAIN, and M. POLANYI. **II.** M. CALVIN, D. D. ELEY, and M. POLANYI (Trans. Faraday Soc., 1936, 32, 1436—1443, 1443—1446).—I. Crystals of phthalocyanine (I) and Cu phthalocyanine (II) can activate H<sub>2</sub>. They show at. interchange with H<sub>2</sub>, catalyse the at. interchange between H<sub>2</sub> and H<sub>2</sub>O (activation energy 6 kg.-cal.), and catalyse the formation of H<sub>2</sub>O from H<sub>2</sub> and O<sub>2</sub> (activation energy 18 kg.-cal.).

**II.** The conversion of para-H<sub>2</sub> into normal H<sub>2</sub> is catalysed by (I) and (II), the activation energies being 5700 and 5000 g.-cal., respectively. The positive temp. coeff. shows that the reaction involves a disruption of the H-H linking by chemisorption.

E. S. H.

**Promoter action of platinic chloride on Raney nickel catalyst.**—See this vol., 1237.

**Catalytic transformations of heterocyclic compounds.**—See this vol., 1264.

**Electrolytic oxidation of graphite in fused alkali.** V. SIHVONEN and K. VOHLONEN (Suomen

Kem., 1936, 9, A, 67—69).—A cylinder of purest natural graphite is used as anode, immersed in either molten NaOH or a mixture of NaOH and KOH, at 500° approx. No org. compounds are found after electrolysis. The carbonate produced and the H<sub>2</sub> evolved correspond closely with that calc. from the current consumption. The bearing of the results on theories of the combustion of graphite is discussed.

D. C. J.

**Oxidation of cobalt amalgam.** F. P. DWYER and J. W. HOGARTH (J. Proc. Roy. Soc. New South Wales, 1936, 69, Part 2, 105—110).—Co amalgam is prepared by electrolysis of aq. CoSO<sub>4</sub> at various c.d. In all cases the isolated compound is Co<sub>2</sub>Hg<sub>3</sub>. Rapid atm. oxidation causes the separation of a fine, black powder, Co<sub>2</sub>O, which subsequently decomposes into CoO and Co in pyrophoric condition. The oxidation product has powerful reducing properties.

E. A. R.

**Corrosion protection of iron.**—See B., 1936, 888.

**Electrolytic removal of iron from solutions of aluminium salts.**—See B., 1936, 738.

**Alkaline plating baths containing ethanolamines.**—See B., 1936, 746.

**Rate of linear crystallisation KG<sub>1</sub> of silver peroxide deposited at the anode.** A. GLAZUNOV and L. SCHLEICH (Coll. Czech. Chem. Comm., 1936, 8, 306—312).—The linear velocity of crystallisation of anodic Ag<sub>2</sub>O<sub>2</sub> deposit from AgNO<sub>3</sub> solutions obeys the same laws as similar cathodic deposits. The rate of crystallisation increases with c.d. and with decreasing electrolyte concn.

C. R. H.

**Electrolysis of solutions of titanium salts.** (MME.) H. EMMANUEL-ZAVIZZIANO and M. HAISSINSKY (Compt. rend., 1936, 203, 161—163).—Electrolysis of Ti(SO<sub>4</sub>)<sub>2</sub> in 0.1N-H<sub>2</sub>SO<sub>4</sub> containing Na<sub>2</sub>SO<sub>4</sub> affords, with a Au-Hg, Ag-Hg, or Pt cathode, pertitanic acid, with a Zn cathode, a basic Ti<sup>IV</sup> salt, and with a Pb cathode, Ti<sup>III</sup> or TiO in an atm. of H<sub>2</sub> or if the electrolyte contains I<sup>-</sup> and has been exactly neutralised with aq. NH<sub>3</sub>.

J. G. A. G.

**Electrolytic formation of sodium perborate.** I. R. MATSUDA (Bull. Chem. Soc. Japan, 1936, 11, 456—464).—In the electrolysis of Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> solution to form NaBO<sub>3</sub>, the presence of Na<sub>2</sub>CO<sub>3</sub> was indispensable. The current efficiency was not impaired by dispensing with the diaphragm. The influence of K<sub>2</sub>CrO<sub>4</sub>, K<sub>2</sub>SO<sub>4</sub>, and KCl was investigated. Electrolysis of metaborate solutions resulted in poor yields of NaBO<sub>3</sub>.

C. R. H.

**Oxidation processes at the cathode.** O. K. KUDRA and K. N. IVANOV (J. Physical Chem., 1936, 40, 769—777).—The powder-like deposits of Cu, Zn, Cd, and Ag formed at cathodes during electrolysis of aq. solutions of their salts at high c.d. are dispersed and contain oxides, formed by secondary oxidation at the cathode. The oxide content depends principally on the oxidising capacity of the anion present, but also on the readiness of oxidation of the metal deposited. Cu, Cd, Cu<sub>2</sub>O, and ZnO so produced have greatly enlarged lattices, due to absorption of H<sub>2</sub>, but Zn and Ag have normal parameters. It is considered that the formation of spongy deposits

during electrolysis of Cd and Zn solutions at very low and at very high c.d. is associated in each case with oxidising conditions at the cathode. J. W. S.

**Photodissociation of complex molecules.** A. TERENIN (Acta Physicochim. U.R.S.S., 1935, 3, 181—194).—The localisation of the electronic transition, the interaction of separate parts of the mol., and the distribution of the absorbed energy during the optical excitation and dissociation of polyat. mols. are discussed. O. J. W.

**Induced predissociation in the kinetics of photochemical reactions.** V. KONDRATEEV (Acta Physicochim. U.R.S.S., 1935, 3, 203—204).—A discussion of previous work. O. J. W.

**Action of inhibitors in the photochemical dissociation of hydrogen peroxide.** B. DAIN and A. SCHWARZ (Acta Physicochim. U.R.S.S., 1935, 3, 291—302).—The inhibition by ketones of the photochemical decomp. of  $H_2O_2$  has been studied and the mechanism of the inhibiting action is discussed. O. J. W.

**Possible correlation between the intensity of cosmic radiation and the velocity of certain chemical reactions.** J. REBOUL (Compt. rend., 1936, 203, 245—246; cf. this vol., 943).—Sheets of Zn and Cd cause slightly greater action on a photographic plate in their close proximity when exposed to cosmic radiation than when enclosed in a Pb screen 20 cm. thick, and also slightly greater action when on a tower 20 cm. high than when in a deep cave. The effect is

attributed to the formation of  $H_2O_2$  through secondary emission from the metal under the action of cosmic radiation. J. W. S.

**Kinetics of halogen atom recombination, and in particular the significance of convection.** E. RABINOWITSCH (Z. physikal. Chem., 1936, B, 33, 275—282).—Contrary to the suggestion of Hilferding and Steiner (this vol., 293), convection currents played a negligible part in the author's experiments on the optical dissociation of  $Br_2$  mols. (*ibid.*, 788). The optically determined recombination consts. of  $Br + Br + X \rightarrow Br_2 + X$  are probably more trustworthy than these authors' vals. R. C.

**Photo-sensitisation of films of potassium by means of hydrogen.** R. C. L. BOSWORTH (Trans. Faraday Soc., 1936, 32, 1369—1375).—Monat. films of K on W do not react with  $H_2$  at temp. < volatilising point, but react with at. H to form a "WKH" surface, which can absorb more K to give a sensitive "WKHK" surface. A more sensitive surface is obtained by depositing K on a "WH" surface. E. S. H.

**Photochemical oxidation of carbon monoxide in the Schumann region.** B. POPOV (Acta Physicochim. U.R.S.S., 1935, 3, 223—244).—The oxidation of CO by at. O produced by the photodissociation of  $O_2$  in the region  $\lambda < 1750$  A. has been studied at 0.1 mm. and at low temp. The reaction is heterogeneous and has a very small energy of activation. Contrary to the case of the oxidation of CO by O produced by discharge, the efficiency of collisions on the wall is large, and is explained by the participation of excited O' atoms ( $^1D$ ) together with normal O atoms in the reaction, which proceeds according to  $CO_{ads} + O' \rightarrow CO_2$ . O. J. W.

**Photochemical oxidation of nitrogen.** V. KONDRATEEV (Acta Physicochim. U.R.S.S., 1935, 3, 247—253).—Experiments on the photochemical oxidation of N and of CO by O, and of CO by NO, as well as on the photodissociation of NO, are described. The addition of CO and  $H_2$  to the mixture of  $N_2 + O_2$  increases the yield of NO, during the photochemical oxidation. The mechanism of this is discussed. O. J. W.

**Theory of photochemical reactions and chemiluminescence in solutions.** B. SVESHNIKOV (Acta Physicochim. U.R.S.S., 1935, 3, 257—268).—The theory of the quenching of fluorescence in solutions is discussed, particularly with regard to the influence of the viscosity of the solvent. Some experiments described indicate that there is a decrease of the quenching of excited mols. in aq. glycerol solutions with increase of viscosity. O. J. W.

**Rôle of oxygen in photo-sensitisation in solutions.** II. E. V. SCHPOLSKI and A. A. ILJINA (Acta Physicochim. U.R.S.S., 1935, 3, 269—289; cf. this vol., 809).—The effect of  $O_2$  on Eder's reaction has been studied, using eosin and  $FeCl_3$  as fluorescent and non-fluorescent sensitizers, respectively. The presence or absence of  $O_2$  influences the sensitisation process considerably, but it is not possible to conclude whether  $O_2$  is indispensable for the photo-sensitisation

in the reaction studied. The influence of  $\text{Na}_2\text{SO}_3$  on the rate of the sensitised reaction is also described.

O. J. W.

**Alteration of lead oxides by light and pressure.** J. HOFFMANN (Z. anorg. Chem., 1936, 228, 160—168).—The influence of visible light, Ra radiations, and pressure on the appearance of  $\text{Pb}_2\text{O}$ ,  $\text{PbO}$ ,  $\text{Pb}_3\text{O}_4$ , and  $\text{PbO}_2$  is described.

E. S. H.

**Oxidation reactions under the influence of light.** H. J. SCHUMACHER (Z. Elektrochem., 1936, 42, 522—529).—Published work is reviewed and the reactions are classified in three groups: the light is absorbed by (1)  $\text{O}_2$ , (2) the mol. undergoing oxidation, or (3) a foreign mol. (sensitised reactions).

E. S. H.

**Photochemical investigations in the extreme ultra-violet.** W. GROTH (Z. Elektrochem., 1936, 42, 533—535).—A modified Xe lamp, in which the resonance lines at 1295 and 1469 Å. are obtained free from C or other lines, is described. Preliminary experiments on photochemical reactions of  $\text{CO}_2$ ,  $\text{NH}_3$ , and  $\text{O}_2$  are reported.

E. S. H.

**Optical sensitisation of silver halides. IV. Chain mechanism of the optical sensitisation of silver bromide.** J. I. BOKINIK and Z. A. ILJINA (Acta Physicochim. U.R.S.S., 1935, 3, 383—396; cf. A., 1933, 35).—A method for determining the "sensitising yield" in the sensitisation of unprotected AgBr sols by erythrosin is described. The "yield" represents the ratio of Ag deposited to the amount of dye adsorbed. It is independent of the amount of dye adsorbed, but is influenced by the  $p_{\text{H}}$  of the sol and, within certain limits,  $\propto$  the time of illumination. Some suggestions concerning the behaviour of the sensitising mol. during photolysis are made.

O. J. W.

**Optical sensitisation of photochemical reactions in solids.** A. J. RABINOVITSCH (Acta Physicochim. U.R.S.S., 1935, 3, 368—382).—Previous work on the action of sensitisers in photochemical reactions is reviewed. Curves showing the sensitising action of erythrosin and other dyes on AgBr are recorded. It is suggested that in solid systems the energy evolved in the photo-oxidation of the adsorbed sensitiser by atm.  $\text{O}_2$  is utilised in the decomp. of the crystals.

O. J. W.

**Influence of polarised light on silver halides coloured by colloids (Weigert effect).** S. TSCHERDINCEV (Acta Physicochim. U.R.S.S., 1935, 3, 355—360).—The dichroism of cryst. plates of AgCl, coloured by exposure to light, has been studied. Absorption curves are given.

O. J. W.

**Photographic reversal with monochromatic and heterogeneous X-rays.** K. PROSAD, S. BASU, and B. N. GHOSH (Z. Physik, 1936, 102, 259—271).—Photographic reversal and multiple reversal have been studied using heterogeneous X-rays from Cu, Fe, and Pt anticathodes, and monochromatic X-rays obtained by spectral decomp. with NaCl and calcite crystals. With Cu and Pt as anticathodes, two reversal ranges were found, but monochromatic rays gave only one reversal during an exposure time of 10 hr. The causes of reversal are discussed. Part of the blackening curve can be explained by the Blair-Leighton theory

4 K

that the formation of the latent image is the result of a reversible chemical decomp. (A., 1932, 1006).

A. J. M.

**Photochemical studies. XXIII. Photochemical decomposition of acetone vapour near 1900 Å. Comparison with the decomposition at longer wave-lengths.** J. P. HOWE and W. A. NOYES, jun. (J. Amer. Chem. Soc., 1936, 58, 1404—1412; cf. this vol., 944).—The quantum yield is independent of the radiation intensity over wide limits, increases with decreasing  $\text{CO Me}_2$  pressure to a limiting val. 0.65, increases on addition of  $\text{N}_2$ ,  $\text{CO}_2$ , or  $\text{C}_2\text{H}_6$ , and is apparently increased by the action of excited Hg. Fluorescence was not detected. The results are discussed.

E. S. H.

**Primary process of the light-rearrangement of o-nitrobenzaldehyde.** L. KUCHLER and F. PATAT (Z. Elektrochem., 1936, 42, 529—532).—The quantum yield in the gaseous phase at 4 mm. pressure is  $0.75 \pm 0.07$ . Addition of  $\text{N}_2$  gives a quantum yield of 0.5 at 1 atm. in agreement with the val. obtained when the reaction occurs in solution.

E. S. H.

**Study of kinetics of a photochemical reaction by means of ultra-violet spectrophotometry. Decomposition of vitamin-A.** P. DUBOULEZ (J. Chim. phys., 1936, 33, 532—545).—Rates of transformation of the reactant and the products are deduced from a series of spectrophotometric curves. The decomp. of vitamin-A by  $\lambda$  3650 Å. does not follow the same course in EtOH as in  $\text{C}_6\text{H}_{14}$ .

J. G. A. G.

**Emission of radiation by chemical reactions.** R. AUDUBERT (J. Chim. phys., 1936, 33, 507—525).—Details are given of results already summarised (this vol., 778, 407). In addition the approx. spectral distribution of the ultra-violet light emitted during the several reactions has been determined. The intensity of the radiation emitted when pyrogallol and  $\text{Na}_2\text{S}_2\text{O}_4$  are oxidised varies approx. parallel with the corresponding instantaneous rate of  $\text{O}_2$  absorption.

J. G. A. G.

**Action of X-rays on glucose.**—See this vol., 1094.

**Reduction and oxidation by ultra-violet-irradiated sugar.**—See this vol., 1094.

**Photochemical reaction of polyatomic molecules as represented by carbonyl compounds.** R. G. W. NORRISH (Acta Physicochim. U.R.S.S., 1935, 3, 171—177).—A summary of previous work. The transfer of energy in mols. by an internal process analogous to a "collision of the second kind" is discussed.

O. J. W.

**Photochemical polymerisation of butadiene.** V. K. NIKIFOROV and P. M. RUNTZO (Acta Physicochim. U.R.S.S., 1935, 3, 335—339).—Commercial gaseous butadiene polymerises when exposed to the light of a quartz-Hg lamp, but with the pure liquid substance there is no polymerisation. The mechanism of polymerisation processes is discussed.

O. J. W.

**Photo-reduction of fluorescent substances by visible light.** J. WEISS (Trans. Faraday Soc., 1936, 32, 1331—1332).—Published work (cf. this vol., 11) is discussed.

E. S. H.

Use of photographic films as a means of measuring  $\gamma$ -ray dosage. R. PAYNE-SCOTT (J. Cancer Res. Comm. Sydney, 1936, 7, 170—175).—Doses of  $\gamma$ -rays may be measured by means of the darkening of photographic films exposed to the rays and developed under standard conditions. The error varied from 4 to 12% according to the type of film. W. O. K.

Photographic action of slow protons. R. KOLLATH (Ann Physik, 1936, [v], 26, 705—722).—The photographic activity of protons of 30—1000 volts with regard to Schumann plates has been determined. In experiments with gelatin plates and films there was considerable halation, due to the positive charge imparted to the plate, but Schumann films on Ag gave satisfactory results. The reciprocity law was obeyed. Blackening increases with the proton intensity, but not linearly. The relative sensitivity of the Schumann plate to protons of various energies was determined, and the abs. sensitivity to 350-volt protons was calc. to be  $0.25 \times 10^8$  per coulomb per sq. cm. The sensitivity of Schumann plates to electrons and protons was compared. The plates have the same sensitivity to slow protons and slow electrons of the same energy. A. J. M.

Exchange between di- and tri-hydroxybenzenes and heavy water.—See this vol., 1104.

Reactions between dry inorganic salts. III. E. B. THOMAS [with L. J. WOOD] (J. Amer. Chem. Soc., 1936, 58, 1341—1344; cf. A., 1935, 832).—In 57 of the 60 possible reactions between the fused halides of Li, Na, K, Rb, and Cs, (1) the reactions proceed in such a direction that the average cube edge of the stable pair is < that of the reciprocal pair, (2) the sum of the heats of formation of the stable pair is > that of the reciprocal pair, (3) the stable pair has the cation of greater at. wt. united with the anion of greater at. wt. and the cation of smaller at. wt. united with the anion of smaller at. wt. E. S. H.

Metallic alkoxides. P. BRUN (Compt. rend., 1936, 203, 315—316).—Dry alcohols were added to dry  $\text{Et}_2\text{O}$  into which dipped two electrodes, one of Pt, the other of the metal to be studied, and the current produced was measured. For the same alcohol K reacted more vigorously than Na, with the production of a greater current. MeOH was more reactive than EtOH. With an alcohol concn. of 1 mol. per litre the current was of the order of  $50 \times 10^{-8}$  amp. The reaction between alcohols and amalgams was also studied. C. R. H.

Thermal decomposition of simple and complex cyanides in the formation of alkali metals, especially potassium. B. ORMONT and B. A. PETROV (Monatsh., 1936, 68, 171—187).—The thermal decomp. of  $\text{K}_4\text{Fe}(\text{CN})_6$  in a vac. gives a few % of K at  $600^\circ$  and 50—80% at  $900^\circ$ , due partly to the capture of electrons by  $\text{K}^+$  ions, but mainly to the reactions  $\text{K}_4\text{Fe}(\text{CN})_6 = 4\text{KCN} + \text{FeC}_2 + \text{N}_2$ ,  $4\text{KCN} = 4\text{K} + 4\text{C} + 2\text{N}_2$ . No  $\text{K}_3\text{Fe}(\text{CN})_6$  is formed.  $\text{K}_3\text{Fe}(\text{CN})_6$  decomposes at  $400\text{—}500^\circ$ :  $\text{Fe}(\text{CN})_6''' + 3\text{K} = 3\text{K} + \text{FeC}_2 + 4\text{C} + 3\text{N}_2$ ,  $3\text{K}_3\text{Fe}(\text{CN})_6 + 3\text{K} = 3\text{K}_4\text{Fe}(\text{CN})_6$ . The  $\text{FeC}_2$  formed as above and by the decomp. of  $\text{H}_4\text{Fe}(\text{CN})_6 \cdot 2\text{Et}_2\text{O}$  is not a compound, but contains

an intimate mixture of  $\alpha$ -Fe and graphite. In presence of  $\text{N}_2$ , up to approx. 90 mm., the velocity of decomp. of  $\text{K}_4\text{Fe}(\text{CN})_6$  at  $900^\circ$  decreases, owing to the formation of labile Fe nitrides.  $\text{Li}_4\text{Fe}(\text{CN})_6$  gives some Li on heating, and a mixture of equal quantities of Na and K salts gives NaK. R. S. B.

Salt hydrates. R. DUBRISAY and J. LEFOL (Compt. rend., 1936, 203, 248—250).—The dehydration of  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  (with excess of  $\text{H}_2\text{O}$ ) in presence of  $\text{P}_2\text{O}_5$  and at 8 mm. pressure has been studied. A sharp break in the wt.-time curve is found at  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ , but a steady decrease is then found to  $\text{CuSO}_4 \cdot \text{H}_2\text{O}$ . Replacement of the  $\text{P}_2\text{O}_5$  by  $\text{H}_2\text{SO}_4\text{—H}_2\text{O}$  mixture of  $\text{H}_2\text{O}$ -v.p. 0.85 mm. decreases the velocity of dehydration considerably, and after 10 days the wt. remains const. and corresponding with  $\text{CuSO}_4 \cdot 3\text{H}_2\text{O}$ . In presence of  $\text{P}_2\text{O}_5$  this dehydrates to  $\text{CuSO}_4 \cdot \text{H}_2\text{O}$ . Rehydration curves have also been traced. J. W. S.

Double iodides of copper and ammonium. (Mlle.) D. MONTAGNON (Compt. rend., 1936, 203, 325—327).— $\text{NH}_4\text{Cl}$  and KI were added to an aq.  $\text{NH}_3$  solution of  $\text{Cu}(\text{OH})_2$ , and, according to the conditions of heating the mixture,  $\text{Cu}_2\text{I}_2 \cdot 3\text{NH}_4\text{I} \cdot \text{NH}_3\text{OI} \cdot 6\text{H}_2\text{O}$  and  $\text{CuI}_2 \cdot 3\text{NH}_3 \cdot 11\text{H}_2\text{O}$  were formed. The latter compound absorbed  $\text{H}_2\text{O}$  and  $\text{NH}_3$  to form  $\text{CuI}_2 \cdot 5\text{NH}_3 \cdot 3\text{H}_2\text{O}$ . C. R. H.

Concentrated copper sulphate solution gives on impure iron, polished and deprived of active dust, a phenomenon recalling that of Evans for rust. P. RONCERAY (Bull. Soc. chim., 1936, [v], 3, 1687—1689).—The effect produced by a drop of aq.  $\text{CuSO}_4$  (25—30%) on clean Fe is, unlike the Evans effect, due to spreading of the drop. The Fe in the exterior of the zone is attacked most, due to the production of a Cu-Fe cell. If active dust remains on the surface this effect is replaced by the Evans effect. J. W. S.

Basic phosphates of bivalent metals. I. Basic magnesium phosphate. R. KLEMENT (Z. anorg. Chem., 1936, 228, 232—240).—Hydrolysis of  $\text{MgHPO}_4 \cdot 3\text{H}_2\text{O}$  yields  $\text{Mg}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$ ,  $\text{Mg}_3(\text{PO}_4)_2 \cdot 0.33\text{Mg}(\text{OH})_2 \cdot 9\text{H}_2\text{O}$ , or  $\text{Mg}_3(\text{PO}_4)_2 \cdot \text{Mg}(\text{OH})_2 \cdot 9\text{H}_2\text{O}$ , according to the hydrolytic agent. E. S. H.

Preparation of calcium and sodium hydrogen sulphides. I. N. OSTROVSKI and I. L. SCHERESCHEVSKI (J. Appl. Chem. Russ., 1936, 9, 1214—1220).— $\text{H}_2\text{S}$  is passed into a 20% suspension of CaO at  $20^\circ$ , with stirring, when the solution at saturation contains 38.5% of  $\text{Ca}(\text{SH})_2$ . 39% aq. NaSH is obtained from this solution by adding anhyd.  $\text{Na}_2\text{CO}_3$  at room temp. The reaction is not affected by admixture of 5% of  $\text{CO}_2$  to the  $\text{H}_2\text{S}$ . R. T.

Active oxides. XCVI. Temperature increments of the intermediate processes in the combination of zinc oxide with ferric oxide. G. F. HUTTON, M. EHRENBERG, and H. KITTEL (Z. anorg. Chem., 1936, 228, 112—126; cf. this vol., 441).—Determinations of  $d$ , hygroscopicity, and magnetic susceptibility have been carried out with mixtures of powdered  $\text{ZnO}$  and  $\text{Fe}_2\text{O}_3$ , after heating at different

temp. for definite intervals. Intermediate steps are identified. E. S. H.

**Precipitation of mercuric iodide.** P. G. PATER-NOSRO (Rev. Fac. Cienc. Quim. La Plata, 1935, 10, 11—18).—The formation of  $\text{HgI}_2$  from solutions of  $\text{HgCl}_2$  and KI has been studied under various conditions of concn. and temp. The most perfect and readily filtered crystals are obtained by mixing boiling 0.02*N* solutions. F. R. G.

**Mercurous salts and their amido-compounds.** II. E. GLEDITSCH and T. F. EGIDIUS (Z. anorg. Chem., 1936, 228, 249—254; cf. this vol., 574).— $\text{Hg}_2\text{NH}_2\text{Cl}$  is a single compound, stable at room temp. when dry. In presence of aq.  $\text{NH}_3$  it decomposes into  $\text{HgNH}_2\text{Cl} + \text{Hg}$ . Similar observations hold for  $\text{Hg}_2\text{NH}_2\text{NO}_3$ . E. S. H.

**Boron hydrides. XXIV. Borane salts.** A. STOCK and H. LAUDENKLOS (Z. anorg. Chem., 1936, 228, 178—192; cf. this vol., 172).—The prep. of  $\text{Na}_2\text{B}_2\text{H}_6$ ,  $\text{CaB}_2\text{H}_6$ ,  $\text{Na}_2\text{B}_4\text{H}_{10}$ ,  $\text{K}_2\text{B}_2\text{H}_6$ ,  $\text{K}_2\text{B}_4\text{H}_{10}$ , and  $\text{K}_2\text{B}_5\text{H}_9$  is described. When heated at 170° the salts containing  $\text{B}_2\text{H}_6$  remain unaltered; the others lose  $\text{H}_2$ , forming  $\text{K}_2\text{B}_4\text{H}_8$ ,  $\text{Na}_2\text{B}_4\text{H}_8$ , and  $\text{K}_4\text{B}_{10}\text{H}_{16}$ . When heated at 450° the salts containing  $\text{B}_2$  or  $\text{B}_4$  give compounds of the type  $\text{M}_2\text{B}_4\text{H}_6$  or  $\text{M}_2\text{B}_4\text{H}_4$ ;  $\text{K}_2\text{B}_5\text{H}_9$  gives  $\text{K}_2\text{B}_5\text{H}_3$ . Treatment with HCl generally yields the alkali chloride and the corresponding borane;  $\text{K}_2\text{B}_4\text{H}_{10}$  gives  $\text{K}_2\text{B}_4\text{H}_5\text{Cl}_5$ . X-Ray diagrams of the above salts are compared. E. S. H.

**Preparation and properties of aluminium periodate dodecahydrate.** V. BIBER, A. VNUKOVA, and N. KONSCHIN (J. Gen. Chem. Russ., 1936, 6, 873—879).—Freshly pptd.  $\text{Al}(\text{OH})_3$  and  $\text{HIO}_4$  yield  $\text{Al}(\text{IO}_4)_3 \cdot 12\text{H}_2\text{O}$ , for which crystallographic and solubility data are recorded. R. T.

**Hydrogenation of aluminium nitride by active hydrogen.** N. I. KOBOSEV, B. V. JEROFEEV, and V. M. SAVINA (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 389—392).— $\text{NH}_3$  and an Al hydride are formed when  $\text{H}_2$ , or  $\text{N}_2 + 3\text{H}_2$ , is led over AlN (formed by the action of  $\text{NH}_3$  on Al powder at 800—900°) in a discharge tube immersed in liquid air. The reaction must be due to at. H, for which it is suggested as a test; mol.  $\text{H}_2$  has no action on account of the high energy val. of AlN. The Al hydride obtained decomposes spontaneously outside the discharge zone. R. C. M.

**Basic gallium nitrate.** N. A. PUSHIN and R. D. ŽIVADINOVITSCH (Z. anorg. Chem., 1936, 228, 255—256).—The prep. and properties of  $\text{Ga}(\text{OH})_2\text{NO}_3$ ,  $\text{Ga}(\text{OH})_3 \cdot 2\text{H}_2\text{O}$  are described. E. S. H.

**Gallium compounds. I.** P. NEOGI and S. K. NANDI (J. Indian Chem. Soc., 1936, 13, 399—403).—When  $\text{Ga}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , freshly pptd. from  $\text{Ga}(\text{NO}_3)_3$  with  $\text{NaHCO}_3$ , is dried in a vac. it yields the compound  $\text{Ga}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , insol. in org. acids. Dissolution of freshly pptd.  $\text{Ga}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  in the respective acids and crystallisation of the solutions in a vac. yields Ga d-, l-, meso-, and r-tartrates  $\text{Ga}_2(\text{C}_4\text{H}_4\text{O}_6)_3 \cdot 4\text{H}_2\text{O}$ , basic Ga acetate  $4\text{Ga}(\text{OAc})_3 \cdot 2\text{Ga}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$ , basic formate  $\text{Ga}(\text{HCO}_2)_3 \cdot \text{Ga}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$  (I), oxalate  $\text{Ga}_2(\text{C}_2\text{O}_4)_3 \cdot 4\text{H}_2\text{O}$  (hygroscopic), lactate  $\text{Ga}(\text{C}_3\text{H}_5\text{O}_3)_3 \cdot 2\text{H}_2\text{O}$ , citrate  $\text{Ga}(\text{C}_6\text{H}_6\text{O}_7)_3 \cdot 3\text{H}_2\text{O}$ , malate  $\text{Ga}_2(\text{C}_4\text{H}_4\text{O}_5)_3 \cdot 3\text{H}_2\text{O}$ , H

phosphite  $\text{GaH}_3(\text{PO}_3)_2 \cdot \text{H}_2\text{O}$ , and H hypophosphite  $\text{GaH}_3(\text{PO}_2)_2$ . Action of  $\text{Ga}(\text{NO}_3)_3$  on the Na salt yields basic Ga acetate  $\text{Ga}(\text{OAc})_3 \cdot 3\text{Ga}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$ , phosphite  $\text{GaPO}_3 \cdot \text{H}_2\text{O}$ , hypophosphite, and (I). Ga d- and l-tartrates have  $[\alpha] +20.3^\circ$  and  $-20.0^\circ$ , respectively. J. W. S.

**Mechanism of oxidation of carbon.** V. SIVONEN (Svensk Kem. Tidskr., 1936, 48, 185—202).—A lecture.

**Carbon obtained by dehydration of carbohydrate.** G. R. LEVI and A. BARONI (Atti R. Accad. Lincei, 1936, [vi], 23, 441—443).—C prepared from inositol, quebrachitol, glucose, or sucrose by heating at 200° with  $\text{ZnCl}_2$ -HCl cannot be differentiated by the method of Hofmann and Frenzel (A., 1930, 875); the rates of formation of  $\text{CO}_2$  by  $\text{K}_2\text{Cr}_2\text{O}_7$ - $\text{H}_3\text{PO}_4$  at 100°, however, are characteristically different (cf. Balfour and Riley, this vol., 178). F. O. H.

**Activated charcoal. II. Purification by washing with water and by activation.** S. ROYCHOUDHURY, S. K. NANDI, and J. K. BANERJEE (J. Indian Chem. Soc., 1936, 13, 410—418; cf. A., 1931, 1226).—Alternate washing and activation at 800° leads to the removal of the negative charge of a suspension of the charcoal in  $\text{H}_2\text{O}$ . Electrolytes are liberated from the charcoal during each washing. After washing with HCl, the latter cannot be entirely removed at 800°/10 mm., although the charge on the particles is zero. Some samples of very pure charcoal showed a positive charge. Addition of NaOH or NaCl increases the charge on negatively charged particles, whilst HCl and  $\text{H}_2\text{SO}_4$  produce a negative charge on isoelectric charcoal. J. W. S.

**Minimum temperature of oxidation of silicon.** C. BEDEL (Compt. rend., 1936, 203, 323—325).—The min. temp. of oxidation of Si in dry  $\text{O}_2$  is approx. 850° and is certainly  $<800^\circ$ . In the presence of  $\text{H}_2\text{O}$  vapour oxidation begins at approx. 430°. C. R. H.

**Behaviour of titanium dioxide on heating and its behaviour towards ferric, sodium, and magnesium oxides.** E. JUNKER (Z. anorg. Chem., 1936, 228, 97—111).— $\text{TiO}_2$  has m.p. about 1800°. At higher temp. dissociation occurs. The heat of reaction of  $0.5\text{Ti}_2\text{O}_3 + 0.5\text{O}_2 = \text{TiO}_2$  is 99,000 g.-cal. The transformation temp. of rutile into brookite is 1300°.  $\text{TiO}_2$  reacts with C in presence of CO at  $>870^\circ$  forming  $\text{Ti}_2\text{O}_3$ ; at temp.  $>$  m.p.,  $\text{Ti}_2\text{O}_3$  and TiC are formed. Equilibrium in the system  $\text{Ti}_2\text{O}_3$ -TiC has been studied.  $\text{TiO}_2$  is reduced to  $\text{Ti}_2\text{O}_3$  when heated in  $\text{H}_2$ ; in  $\text{N}_2$  some  $\text{Ti}_2\text{O}_3$  is formed by dissociation.  $\text{Ti}_2\text{O}_3$  has m.p. about 1900°. The m.p. of  $\text{TiO}_2$ - $\text{Ti}_2\text{O}_3$  mixtures have been determined. The system  $\text{TiO}_2$ - $\text{Fe}_2\text{O}_3$  has been investigated. Ilmenite has m.p. about 1350°. The  $\text{TiO}_2$ -rich end of the  $\text{TiO}_2$ - $\text{Na}_2\text{O}$  equilibrium diagram has been investigated and the existence of  $\text{Na}_2\text{O} \cdot 3\text{TiO}_2$  confirmed. M.p. data for the system  $\text{TiO}_2$ - $\text{Ti}_2\text{O}_3$ -MgO have been determined. E. S. H.

**Titanium. I. Preparation of  $\text{TiNCl}$ ,  $\text{TiCl}_4$ .** II. Action of oxygen on titanium tetrachloride under the influence of the silent electrical discharge. III. Formation of titanium di-iodide

from titanium tetrachloride and potassium iodide, and attempts to convert it into titanium iodoform. L. HOCK and W. KNAUFF (Z. anorg. Chem., 1936, 228, 193—199, 200—203, 204—208).—I.  $TiNCl_4$  has been prepared by the action of the silent electrical discharge on  $TiCl_4$  and  $N_2$ .

II. The yellow reaction product consists of a mixture of  $TiCl_4$  and  $TiO_2$ .

III.  $TiCl_4$  and KI yield  $TiI_2$ .  $TiI_2$  and HI do not yield  $TiHI_3$ . E. S. H.

**Generalised prototropy.** C. PREVOST (Bull. Soc. chim., 1936, [v], 3, 1666—1673).—The possibility is propounded that a proton may be liberated from the atom to which it is normally bound by co-valency and be attached to an atom with a lone pair of electrons. This phenomenon, called generalised prototropy, will not cause isomerism but renders the mol. susceptible to reagents. It is used to explain diverse oxidations, e.g.,  $H\cdot PO(OH)_2 \rightarrow P(OH)_3 \rightarrow O:P(OH)_3$ ,  $RCHO \rightarrow RC:OH \rightarrow RCO_2H$ ,  $CHCl_3 \rightarrow CCl_2\cdot Cl\cdot H \rightarrow O:CCl_2\cdot Cl\cdot H$ ,  $COCl_2 + HCl$ . A similar migration of Me, termed methylenic dehydration, is applied thus:  $CR_3\cdot CH_2\cdot OH \rightarrow CR_3\cdot CH \rightarrow CR_2\cdot CHR$ ; by analogy the mechanism,  $CHR_2\cdot CH_2\cdot OH \rightarrow CHR_2\cdot CH \rightarrow CR_2\cdot CH_2$ , is proposed. R. S. C.

**New type of vanadyl salicylate.**—See this vol., 1107.

**Reaction of arsenious oxide with oxides of heavy metals at high temperatures.** I. M. DUBROVIN (J. Appl. Chem. Russ., 1936, 9, 1049—1056).— $As_2O_3$  begins to combine with  $ZnO$  at  $250^\circ$ , and at  $400^\circ$  the production of  $Zn_3(AsO_3)_2$  is at a max.;  $As^V$  is absent. At  $500^\circ$   $As^{III}$  and  $As^V$  are present in approx. equal amounts, but the total As content is at a min. owing to volatilisation. Mixtures heated at  $600^\circ$  contain only  $As^V$ ; with rising temp. above  $600^\circ$  the rate of combination rises to a max. at  $700^\circ$ , thereafter remaining const. Formation of  $Pb_3(AsO_3)_2$  commences at  $250^\circ$ , and is associated with oxidation to  $Pb_3(AsO_4)_2$  (I) at  $250$ — $300^\circ$ ; with rising temp. the amount of combined As falls to a min. at  $350$ — $450^\circ$  (loss of  $As_2O_3$  by volatilisation), whilst at  $450$ — $800^\circ$  the product consists exclusively of (I). Combination, associated with oxidation of  $As^{III}$  to  $As^V$ , takes place between  $Fe_2O_3$  and  $As_2O_3$  at  $225^\circ$ , and is at a max. at  $250^\circ$ . With rising temp. above  $250^\circ$  the amount of combined As falls to a min. at  $500^\circ$ , due to thermal decomp., and then rises to a const. level at  $600$ — $700^\circ$ , when exclusively  $As^V$  is present. R. T.

**Conductometric titrations of the isomeric chromic chlorides with silver nitrate.** N. H. LAW (Trans. Faraday Soc., 1936, 32, 1461—1465).—In aq. solution the violet compound yields  $3Cl'$ . The pale green compound yields  $2Cl'$ , except in solutions of  $p_H$  approx. 5, when all the  $Cl$  is ionised. The dark green compound yields  $1Cl'$  in strongly acid solutions, but with increasing  $p_H$  the ionisable  $Cl$  increases, ionisation eventually becoming complete. E. S. H.

**Chromous and chromic ammines.** J. H. BALTHUS, jun., and J. C. BAILLAR, jun. (J. Amer. Chem. Soc., 1936, 58, 1474—1476).—The prep. and

properties of  $[Cr en_3]Cl_3 \cdot 3.5H_2O$ ,  $[Cr en_2]Br_3 \cdot 3H_2O$ ,  $[Cr(NH_2\cdot CHMe\cdot CH_2\cdot NH_2)_3]Cl_3 \cdot H_2O$ ,  $[Cr\{(CHMe\cdot NH_2)_2\}_3]I_3$ ,  $[Cr_4(OH)_6 en_6]Br_6 \cdot 4H_2O$ , and  $[Cr(C_5H_5N)_2]Cl_2$  are described. Corresponding  $Cr^{II}$  compounds (except the  $C_5H_5N$  derivatives) cannot be isolated from aq. solution, as they rapidly oxidise to  $Cr^{III}$ . E. S. H.

**Molybdenum chlorohydrin and normal glycol molybdate.** J. BYÉ (Compt. rend., 1936, 203, 321—323).—The solubility of  $MoO_3$  in  $HCl$  has been investigated. Extraction of the solution with  $Et_2O$  yields an indefinite compound  $MoO_3 \cdot 2HCl \cdot 2Et_2O + xEt_2O$ . The excess of  $Et_2O$  is easily liberated and under the action of light and moisture the compound loses the combined  $Et_2O$  and becomes blue. In the decomp. products  $MeCHO$  and  $EtOAc$  have been detected. If  $(CH_2)_2O$  is bubbled through an  $Et_2O$  solution of  $MoO_3 \cdot 2HCl$ , normal glycol molybdate is pptd. C. R. H.

**Hydrates of manganese sulphate.** E. RENCKER and P. DUBOIS (Compt. rend., 1936, 203, 185—187).—The existence of hydrates containing 7, 5, 4, 3, and 1 mols. of  $H_2O$  of crystallisation is confirmed; other hydrates reported are probably mixtures.

J. G. A. G.

**The Evans effect is produced on impure iron and is caused by active dust.** P. RONCEBAY (Bull. Soc. chim., 1936, [v], 3, 1661—1668).—The Evans effect (A., 1922, ii, 814; 1924, ii, 599) is associated with active dust left during polishing, the dust being more active in contact with aq.  $NaCl$  than in contact with  $H_2O$ . The effect occurs with impure as well as pure Fe. The thickness of rust in the three zones  $\propto$  the extent of attack in these zones, and therefore contradicts the view that the  $FeCl_2$  migrates towards the exterior alkaline zone. The presence of active dust on even carefully cleaned surfaces is considered to explain the divergent conclusions of various investigators. J. W. S.

**Rhodium chloride,  $RhCl_3$ .** J. MEYER and M. KAWCZYK (Z. anorg. Chem., 1936, 228, 297—300).— $RhCl_3$  can exist in a yellow, ionisable, or brown, non-ionisable form. The analogy with  $Cr^{III}$  compounds is discussed. E. S. H.

**Chromatographic analysis.** A. H. COOK (Chem. and Ind., 1936, 724—726).—A review.

**Determination of  $p_H$  values by the hydrogen and antimony electrodes.** A. T. WILLIAMSON and W. G. OAKES (J. Text. Inst., 1936, 27, T199—203).—A modified rocking H electrode which is simple in construction and rapid in action is described. A  $N_2$ -filled Sb electrode for which  $E = 0.049 + 0.0589p_H$  for solutions containing or free from  $Cl'$  is also described. A. G.

**Determination of the  $p_H$  of natural waters and solutions.** T. T. COCKING (Ind. Chem., 1936, 12, 375—376).—The use of colorimetric methods for natural and condenser waters, paper, soils, and coloured solutions is described. C. W. G.

**Comparison of the glass and quinhydrone electrodes for the measurement of the activity of the hydrogen ion in sucrose solutions.** H. P.

CADY and J. D. INGLE (J. Physical Chem., 1936, 40, 837—843).—The quinhydrone electrode gives a changing potential when the electrode is left in contact with the HCl-quinhydrone solution for long periods, and so gives untrustworthy results in measuring the H<sup>+</sup> activity in sucrose solutions during inversion. The glass electrode yields reproducible results which indicate that this activity remains const. throughout the inversion of sucrose by HCl. J. W. S.

Micro-thermoconductivity method for the determination of para-hydrogen and deuterium. D. D. ELEY and J. L. TUCK (Trans. Faraday Soc., 1936, 32, 1425—1428).—Apparatus and technique are described. E. S. H.

Determination of moisture. See B., 1936, 768.

Determination of moisture by means of calcium carbide. P. M. ORSHEGROVSKI and K. B. CHAIT (J. Appl. Chem. Russ., 1936, 9, 1141—1143).—Commercial CaC<sub>2</sub> contains a small amount of H<sub>2</sub>O, and evolves C<sub>2</sub>H<sub>2</sub> when heated. In determining the H<sub>2</sub>O content of substances by means of CaC<sub>2</sub> the latter should be previously heated until C<sub>2</sub>H<sub>2</sub> evolution ceases. R. T.

Electroanalysis and indirect macro-electroanalysis of anions using three electrodes. J. GUZMAN and L. QUINTERO (Anal. Fís. Quím., 1934, 32, 800—806).—Cl<sup>-</sup>, Br<sup>-</sup>, I<sup>-</sup>, C<sub>2</sub>O<sub>4</sub><sup>2-</sup>, Fe(CN)<sub>6</sub><sup>4-</sup>, and Fe(CN)<sub>6</sub><sup>3-</sup> may be determined to within 0.2% by quant. conversion into their Ag salts, the Ag being determined by Guzman's three-electrode method, using a cathode of Ag-plated brass and an anode of passive Fe wire (cf. A., 1935, 949). F. R. G.

Determination of halides in photographic materials.—See B., 1936, 763.

Qualitative reaction for bromates. F. L. HAHN (Mikrochem., 1936, 20, 236—238).—BrO<sub>3</sub><sup>-</sup> can be detected in presence of KClO<sub>3</sub> and KBr by the greenish-yellow colour which develops on addition of fluorescein, boiling, and making alkaline. R. S.

Absorption of gases and vapours. Determination of traces of volatile bromides. F. L. HAHN (Mikrochem., 1936, 20, 239—243).—Air containing the vapour is passed through a heated SiO<sub>2</sub> tube with H<sub>2</sub>O, and the HBr in the condensate is determined colorimetrically. R. S.

Determination of fluorine.—See B., 1936, 766.

Rapid determination of oxygen in atmospheric gases. A. KLING and M. CLARAZ (Compt. rend., 1936, 203, 319—321).—To 5 c.c. of a solution containing FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> 2 g. and tartaric acid 20 g. per litre, and sufficient methylene-blue to colour, are added 5 c.c. of N-NaOH. The gaseous mixture is bubbled through this solution at a known rate until the blue, which acts as oxidation-reduction indicator, is decolorised, and the vol. of gas passed is noted. The apparatus is calibrated by means of known O<sub>2</sub> mixtures. An accuracy of 0.5% is claimed. C. R. H.

Determination of sulphide-sulphur in pyrites.—See B., 1936, 884.

Use of spot-reactions in the identification of substances soluble with difficulty in acids. F.

FEIGL (Mikrochem., 1936, 20, 198—208).—Spot-reactions are described for insol. sulphides, insol. sulphates, Ag halides, Fe<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>, Cr<sub>2</sub>O<sub>3</sub>, CrCl<sub>3</sub>, MnO<sub>2</sub>, PbO<sub>2</sub>, WO<sub>3</sub>, W, Mo, SiO<sub>2</sub>, Si, Sb<sub>2</sub>O<sub>5</sub>, insol. fluorides, SnO<sub>2</sub>, and Sn<sub>3</sub>(PO<sub>4</sub>)<sub>4</sub>. R. S.

Rapid dynamic method of determining sulphur dioxide in air. D. N. FINKELSCHTEIN (J. Appl. Chem. Russ., 1936, 9, 1347—1358).—Gurevitch's colorimetric method, depending on absorption of SO<sub>2</sub> in acid aq. BaCrO<sub>4</sub>, boiling, and pptn. of unchanged BaCrO<sub>4</sub> by NH<sub>3</sub>, followed by colorimetric determination of (NH<sub>4</sub>)<sub>2</sub>CrO<sub>4</sub> remaining in solution, gives approx. correct results only for 0.05—0.5 mg. of SO<sub>2</sub>. SO<sub>2</sub> (<0.005 mg.) can be determined with satisfactory accuracy by adding 25 ml. of 5% KClO<sub>3</sub>, 3 ml. of 0.1N-KI, and 1 ml. of 0.05N-KIO<sub>3</sub>, and titrating after 45 min. with 0.002N-Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Alternatively, the H<sub>2</sub>SO<sub>4</sub> produced from SO<sub>2</sub> and aq. KClO<sub>3</sub> is titrated with 0.004N-KOH (Me-red) to *p*<sub>H</sub> 6. A procedure for rapid sampling of air is described. R. T.

Volumetric determination of sulphate.—See B., 1936, 766.

Sulphuric acid as a disperse phase in town air. J. H. COSTE and G. B. COURTIER (Trans. Faraday Soc., 1936, 32, 1198—1201).—A condensation method, whereby filters are avoided, for determining the H<sub>2</sub>SO<sub>4</sub> in air is described. Air freed from SO<sub>2</sub> was almost saturated with H<sub>2</sub>O and passed through an ice-cooled flask, where the large droplets, formed on nuclei of H<sub>2</sub>SO<sub>4</sub>, condensed. Dust and smoke particles passed through the flask. London air contains 1—20 × 10<sup>-6</sup> g. of free H<sub>2</sub>SO<sub>4</sub> per cu.m. High [H<sub>2</sub>SO<sub>4</sub>] was found during calm and foggy conditions and, also, in general, when [SO<sub>2</sub>] was high. J. G. A. G.

Determination of carbon disulphide.—See B., 1936, 869.

Bromometric determination of thiocyanates. Application to micro-analysis and analysis of thiocyanate complexes. E. KAHANE and R. COUPECHOUX (Bull. Soc. chim., 1936, [v], 3, 1588—1595).—Treadwell and Mayr's method (A., 1916, ii, 264) for the determination of CNS<sup>-</sup> (treatment with KBr and KBrO<sub>3</sub>, addition of KI, and titration with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>) gives good results if the KI is added as soon as possible after the KBrO<sub>3</sub>. 0.001 g. of KCNS can be determined in this way to within ±2%. The method can also be used for determination of Reinecke's salt or similar complexes. J. W. S.

Determination of selenium in steel.—See B., 1936, 793.

Determination of tellurium in steel.—See B., 1936, 840.

Determination of nitrates in presence of nitrites and certain organic compounds. A. S. VETROV (J. Appl. Chem. Russ., 1936, 9, 1158—1167).—2.5 ml. of 18N-NaOH and 5 ml. of 5N-CO(NH<sub>2</sub>)<sub>2</sub> are added to 20 ml. of meat extract, the solution is heated, and 3 ml. of 18N-H<sub>2</sub>SO<sub>4</sub> are added. The solution is boiled for 5 min. with 3 ml. of 18N-NaOH and excess of KMnO<sub>4</sub>. Excess of Fe(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>2</sub> and 10 ml. of 18N-H<sub>2</sub>SO<sub>4</sub> are then

added, followed by 115 ml. of HCl ( $d$  1.115), air is expelled from the flask by passing  $\text{CO}_2$ , and 3 ml. of 1%  $(\text{NH}_4)_2\text{MoO}_4$  are introduced. The solution is then distilled in a stream of  $\text{CO}_2$ , collecting the issuing gases under aq. NaOH, and the  $\text{HNO}_3$  content of the original extract is derived from the vol. of NO collected. R. T.

Determination of ammoniacal nitrogen in seawater. O. GÓMEZ IBÁÑEZ (Anal. Fis. Quím., 1934, 32, 897—898).—The  $\text{NH}_3\text{-N}$  at various depths at Eddystone has been found by Wattenberg's method of direct Nesslerisation in presence of  $[\text{-CH(OH)CO}_2\text{H}]_2$  to vary from 30 to 0 mg. per cu. m. between February and April. F. R. G.

Determination of phosphates in waters.—See B., 1936, 766.

Analysis of superphosphates.—See B., 1936, 738.

Rapid determination of phosphorus in stainless steels.—See B., 1936, 793.

Progress of the formation of the arsenical mirror in the Marsh apparatus and the determination of small quantities of arsenic. J. GANGL and J. VAZQUEZ SANCHEZ (Anal. Fis. Quím., 1934, 32, 876—890).—The usual form of the Marsh apparatus does not give quant. results. It is essential to use Zn dust to produce sufficient nascent H, and subsequently to boil the liquid for 10 min. to expel all the  $\text{AsH}_3$ , using a spiral quartz tube of 0.2 mm. internal diameter to collect the As, which is then dissolved in ICl and the liberated I titrated in presence of KCN with 0.001M-KIO<sub>3</sub> (for amounts of As up to 1 mg.). The influence of salts on the formation of  $\text{AsH}_3$  has been investigated. The use of special absorbents in the apparatus is unnecessary. F. R. G.

Determination of boron in glass.—See B., 1936, 789.

Determination of silica in iron ores.—See B., 1936, 792.

Determination of carbon dioxide in air. Y. KAUKO and T. YLI-UOTILA (Suomen Kem., 1936, 9, A, 71—72).—An improvement on the usual absorption method for the determination of  $\text{CO}_2$  in air is described. Results obtained by this method are more exact and also give higher abs. vals. D. C. J.

Determination of total carbonic acid in water. A. PEKKARINEN (Suomen Kem., 1936, 9, A, 70—71).—Methods are briefly discussed. D. C. J.

Determination of the total carbonic acid of carbonate solutions. Y. KAUKO, V. MANTERE, and T. YLI-UOTILA (Suomen Kem., 1936, 9, A, 65—67).—Air is passed at a measured rate up a column containing glass beads, and down which the carbonate solution, acidified in its course, passes at a measured rate. The accuracy of the method is limited only by that of the determination of the  $\text{CO}_2$  content of the air used. D. C. J.

Micro-determination of carbon dioxide and hydrogen in elementary analysis. Volumetric determination of carbon dioxide. J. LINDNER [in part with V. RANK] (Mikrochem., 1936, 20, 209—

224).—The absorption of  $\text{CO}_2$  in alkali and  $\text{Ba(OH)}_2$ , and the influence of excess of air are discussed. Suitable sizes of absorption apparatus are given, and errors arising in the titration or from rubber connexions are considered. R. S.

Photo-electric turbidimeter and alkaline titration method for determination of small amounts of hydrocyanic acid. E. T. BARTHOLOMEW and E. C. RABY (J. Assoc. Off. Agric. Chem., 1936, 19, 472—476).—The use of the turbidimeter facilitates the detection of the end-point of the titration. Maceration of the material should take place in a closed vessel; otherwise HCN is lost. The distillate should be clarified with  $\text{PbCO}_3$  to prevent reduction of  $\text{AgNO}_3$  by volatile org. substances. E. C. S.

Detection and determination of hydrogen cyanide.—See B., 1936, 861.

Determination of free cyanide in cadmium-plating solutions.—See B., 1936, 890.

Gravimetric determination of sodium. J. C. CANESSA (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 87—93).—Kahane's method (A., 1930, 726) is more trustworthy in presence of  $\text{Cl}^-$  and  $\text{NO}_3^-$  than of  $\text{SO}_4^{2-}$ . F. R. G.

Determination of total alkali metals in water.—See B., 1936, 766.

Use of formaldehyde for the elimination of ammonia and of ammonium salts. III. Decomposition of ammoniacal complexes by formaldehyde. Determination of metals in solutions containing ammonia or ammonium salts by alkali hydroxides or carbonates. A. HEMMELEK (Annali Chim. Appl., 1936, 26, 240—248; cf. this vol., 303).—The method is applicable to metals (e.g., Ag, Cu, Cd, Zn, Ni, Co) with salts insol. in  $\text{H}_2\text{O}$  but sol. in aq.  $\text{NH}_3$ . Addition of  $\text{CH}_2\text{O}$  to solutions in aq.  $\text{NH}_3$  converts the latter into  $(\text{CH}_2)_6\text{N}_4$  and permits pptn. of the metal as hydroxide or carbonate. F. O. H.

Analysis of calcium fluoride.—See B., 1936, 833.

Causes of contamination of precipitates. I. Precipitation processes in which barium compounds are involved. Z. KARAOGLANOV (Z. anal. Chem., 1936, 106, 129—146; cf. A., 1918, ii, 239, 241).—The author's published work on the pptn. of  $\text{BaSO}_4$  and  $\text{BaCrO}_4$  is discussed. The variability of composition and the nature of the ions co-pptd. in presence of foreign electrolytes are considered to be due to secondary reactions accompanying pptn., leading to the formation of mixed salts, e.g.,  $\text{Ba(KSO}_4)_2$ ,  $(\text{BaCl})_2\text{SO}_4$ . J. S. A.

Sensitive reagents for detection and determination of magnesium. F. P. DWYER (J. Proc. Austral. Chem. Inst., 1936, 3, 224).—A correction (cf. this vol., 1082). *p*-Nitrobenzenediazoaminobenzene gives a strong carmine absorption colour with  $\text{Mg(OH)}_2$ . J. S. A.

Determination of magnesium in glass.—See B., 1936, 884.

Electroanalysis and macro-electroanalysis of zinc with three electrodes. J. GUZMAN and J. S. D'ANGLADA (Anal. Fis. Quím., 1934, 32, 1053—

1066).—A galvanised Fe cathode gave satisfactory results with  $\text{NH}_3$ -Zn solutions containing  $\text{SO}_4^{''}$ ,  $\text{HCO}_2'$ ,  $\text{C}_2\text{O}_4^{''}$ , tartrate, and  $\text{CN}'$  (with a passive Fe anode), and with Zn solutions containing free  $\text{AcOH}$  (with a steel anode). The results are most accurate with the ammoniacal cyanide solutions. The three-electrode indicator potential method is recommended.

D. R. D.

**Micro-reactions of lead.** I. M. KORENMAN and S. S. MESSONSENK (Mikrochem., 1936, 20, 189—193).—The micro-characterisation of  $\text{PbCl}_2$ ,  $\text{PbI}_2$ , and  $\text{K}_2\text{CuPb}(\text{NO}_2)_6$  in presence of other salts is described, and the optimum concns. of  $\text{HCl}$ ,  $\text{KI}$ , and  $\text{H}_2\text{SO}_4$ , respectively, are given.

R. S.

**Determination of lead in pyrites.**—See B., 1936, 833.

**Gravimetric determination of copper by hexamethylenetetramine.** A. HEMMELER (Annali Chim. Appl., 1936, 26, 237—240).—Cu is pptd. by  $(\text{CH}_3)_6\text{N}_4$  (or  $\text{NH}_3 + \text{CH}_2\text{O}$ ), the ppt. being incinerated and weighed as  $\text{CuO}$ . Ag and Zn salts must first be separated, the former being reduced to Ag and the latter partly pptd. by  $(\text{CH}_2)_6\text{N}_4$ .

F. O. H.

**Colour reaction of copper and urobilin.** G. BERTRAND and L. DE SAINT-RAT (Compt. rend., 1936, 203, 140—143).—Urobilin in 60% EtOH gives with  $>0.0001$  mg. of Cu in 1 ml. of 60% EtOH containing  $\text{NaOAc}$  a permanent pink colour which is sp. for Cu and can be used to determine Cu colorimetrically in admixture with other elements and radicals without preliminary separation.

**2:7-Diaminodibenzfuran as a reagent for copper.** E. F. BRAU (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 43—45).—2:7-Diaminodibenzfuran with  $\text{CuSO}_4$  in presence of  $\text{KCN}$ ,  $\text{KCNO}$ , or  $\text{NH}_4\text{CNS}$  gives a blue ppt.

F. R. G.

**Electroanalysis and macro-electroanalysis of copper with three electrodes.** J. GUZMAN and A. SARABIA (Anal. Fis. Quím., 1934, 32, 910—917; cf. A., 1935, 723).—Satisfactory results have been obtained with  $\text{NH}_3$ -Cu solutions containing  $\text{HCO}_2'$ ,  $\text{BO}_3^{''}$ ,  $\text{OAc}'$ ,  $\text{C}_2\text{O}_4^{''}$ , and citrate, and for acid Cu solutions containing  $\text{HCO}_2'$ ,  $\text{NO}_2'$ ,  $\text{SO}_4^{''}$ ,  $\text{PO}_4^{''}$ , and  $\text{OAc}'$ .

D. R. D.

**Determination of copper in brass etc.**—See B., 1936, 889.

**Determination of copper.** I. JOLSON (Z. anal. Chem., 1936, 106, 157—167).—Cu<sup>++</sup> in absence of a great excess of  $\text{NH}_4$  salts is reduced to Cu<sup>+</sup> by means of  $\text{N}_2\text{H}_4$  or  $\text{NH}_2\text{OH} + \text{aq. NH}_3$ . Cu<sup>+</sup> is pptd. by  $\text{C}_2\text{H}_2$  as  $\text{Cu}_2\text{C}_2$ , which is kept in suspension by adding gelatin as protective colloid. The suspension is titrated with 1% or 0.1% aq.  $\text{KCN}$ , being decolorised and converted quantitatively into  $\text{K}_2\text{Cu}(\text{CN})_3$ . In presence of Fe or Zn, 5 g. of  $\text{Na}_4\text{P}_2\text{O}_7$  per 100 c.c. are added. For the determination of Cu in melts from sulphide ores, the material is dissolved in  $\text{HCl} + \text{HNO}_3 + \text{KClO}_3$ , and the solution is evaporated to dryness. Flotation gangue is dissolved similarly, but for the titration of Cu a large excess of  $\text{Na}_4\text{P}_2\text{O}_7$  is necessary. Slags from Cu smelting are evaporated down successively with  $\text{HCl}$ ,  $\text{HNO}_3$ , and  $\text{H}_2\text{SO}_4$ .

J. S. A.

**Induced reduction by silver ion for rapid detection of mercuric, silver, and stannous ions.** N. A. TANANAIEV (Z. anal. Chem., 1936, 160, 167—170).—In presence of a small amount of Ag,  $\text{HgCl}_2$  and  $\text{Hg}_2\text{Cl}_2$  are reduced inductively by  $\text{SnCl}_2$  in acid solution. The reaction may be used for a drop test for Ag, Hg, or (much less sensitive) Sn. Fe<sup>++</sup> should be absent.

J. S. A.

**Colorimetric determination of minute amounts of mercury in organic matter.** N. STRAFFORD and P. F. WYATT (Analyst, 1936, 61, 528—535).—Org. matter is decomposed by hot  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{O}_2$ , using an aq.  $\text{NaOH}$  trap and also one containing aq.  $\text{H}_2\text{S}$ ,  $\text{CuSO}_4$  and paper pulp. The mixed acid and alkaline liquids are neutralised with aq.  $\text{NH}_3$ , oxidised with  $\text{KMnO}_4$ , and the contents of the  $\text{H}_2\text{S}$  trap added. The solution is treated with  $\text{H}_2\text{S}$ , the ppt. washed with  $\text{H}_2\text{S}-\text{H}_2\text{O}$  and then  $\text{COMe.}$ , and free S is removed by  $\text{CS}_2$ . The dry, mixed sulphides are oxidised with  $\text{H}_2\text{SO}_4-\text{HNO}_3$ , a slight excess of aq.  $\text{NH}_3$  is added followed by an excess of  $\text{HNO}_3$ , and the liquid is electrolysed. The Hg on the cathode is dissolved in  $\text{HNO}_3$  and determined colorimetrically with *p*-dimethylaminobenzylidenerrhodanine. The method is considered to be more satisfactory than the colloidal sulphide and the diphenylcarbazide and diphenylcarbazone methods, the disadvantages of which are discussed.

E. H. S.

**Quantitative separation of aluminium and beryllium.** J. DEWAR and P. A. GARDINER (Analyst, 1936, 61, 536—538).—If the Al is not greatly in excess of the Be present, a slight modification of Britton's method (B., 1922, 273) gives accurate results.

E. H. S.

**Colorimetric determination of aluminium with hæmatoxylin.** M. T. GOLUBEVA (J. Appl. Chem. Russ., 1936, 9, 1144—1149).—Hatfield's method (A., 1924, ii, 350) gives satisfactory results with coloured as well as colourless hæmatoxylin. It serves for determination of 0.025—0.6 mg. of Al per litre of  $\text{H}_2\text{O}$  (error  $\pm 5\%$ ); Ca and Mg affect the colour obtained. Low results are obtained when the Al is in the form of hydroxide.

R. T.

**Colorimetric determination of aluminium by means of alizarin-red S.** A. P. MUSAKIN (J. Appl. Chem. Russ., 1936, 9, 1340—1346).—The greatest difference between the intensity of coloration of aq. Na alizarinsulphonate (I) alone and in presence of Al<sup>+++</sup> is at  $p_H$  3.6. 25 mg. of (I) should be taken per mg. of  $\text{Al}_2\text{O}_3$  present. Fe<sup>+++</sup> is removed by adding 1 ml. of 32%  $\text{KCN}$  per 3 ml. of a solution, and extracting with  $\text{C}_5\text{H}_{11}\text{OH}$  (2 successive 1-ml. portions). The colorations remain unchanged for 15 days.

R. T.

**Rational analysis of clays.**—See B., 1936, 834.

**Microchemical test for gallium with morin.** G. BECK (Mikrochem., 1936, 20, 194—197).—Ga may be detected in presence of Al if  $\text{NaF}$  is added, when only the green Ga fluorescence appears. The limiting quantities detectable and the reactions of other salts are given.

R. S.

**Direct photo-electrometric determination of manganese and chromium in the flame.** J.

HEYES (Z. Elektrochem., 1936, 42, 532).—The intensity of the spectral lines is determined by means of a photo-electric cell. The sensitivity is comparable with that of the photographic method.

E. S. H.

Micro-determination of manganese in steel.—See B., 1936, 839.

Determination of traces of iron. J. A. GUY (Chem. and Ind., 1936, 642).—Traces of Fe were determined by dissolving in dil.  $\text{H}_2\text{SO}_4$  and making pink with 0.01N- $\text{KMnO}_4$ . The excess of  $\text{KMnO}_4$  was decolorised with dil.  $\text{H}_2\text{O}_2$ , after which the normal colorimetric method with  $\text{NH}_4\text{CNS}$  was used.

C. R. H.

Electrometric analysis. Depolarimetry and galvanimetry. J. GUZMAN and A. RACANO (Anal. Fis. Quím., 1934, 32, 899—909).—Modifications of the authors' method (A., 1935, 948) for use in determining  $\text{Fe}^{\text{II}}$  and  $\text{H}_2\text{O}_2$  by means of  $\text{KMnO}_4$ ,  $\text{OCl}^-$  by means of  $\text{AsO}_3^-$  and  $\text{Fe}^{\text{II}}$ , and  $\text{H}_2\text{O}_2$  and  $\text{Fe}(\text{CN})_6^{4-}$  by means of  $\text{Ce}(\text{SO}_4)_2$  are described.

D. R. D.

Photometric determination of iron in used engine oils.—See B., 1936, 866.

Separation of iron, aluminium, and chromium from manganese, cobalt, and nickel with pyridine. E. A. OSTROUMOV (Z. anal. Chem., 1936, 106, 170—176).—Pptn. of Fe, Cr, and Al as hydroxides from dil.  $\text{HCl}$  or  $\text{HNO}_3$  solution by means of 20% aq.  $\text{C}_5\text{H}_5\text{N}$  at 60—70°, in presence of  $\text{NH}_4\text{Cl}$  or  $\text{NH}_4\text{NO}_3$ , affords a quant. separation from Mn, Co, and Ni with one pptn. Large amounts of  $\text{SO}_4^{2-}$  should not be present.

J. S. A.

Micro-silicate analysis. II. Determination of iron, aluminium, magnesium, calcium, titanium, and manganese. K. SCHOKLITSCH (Mikrochem., 1936, 20, 247—253).—Fe and Al, and, later, Mg, are separated as 8-hydroxyquinoline compounds, Ca as  $\text{CaC}_2\text{O}_4$ , and Mn is determined colorimetrically. (Cf. A., 1935, 1472.)

R. S.

Argentometric studies. IV. Determination of ferricyanide. O. TOMÍČEK and M. K. HUBROVA (Coll. Czech. Chem. Comm., 1936, 8, 293—305).—The potentiometric titration of  $\text{K}_3\text{Fe}(\text{CN})_6$  with  $\text{AgNO}_3$  in neutral solution was carried out with an accuracy of 0.2%. The sensitivity of the electrode, which consisted of Ag foil soldered to Pt wire, was increased by the addition of  $\text{HNO}_3$  or, better,  $\text{EtOH}$ . The presence of salts of  $\text{NH}_4$ , Na, K, Ca, Sr, Ba, Mg, Al, and Pb lowered the results. In the presence of  $\text{K}_3\text{Fe}(\text{CN})_6$ , titration gives  $\text{K}_4\text{Fe}(\text{CN})_6 + \text{K}_3\text{Fe}(\text{CN})_6$ . If, however, the solution is made acidic with  $\text{H}_2\text{C}_2\text{O}_4$  and the  $\text{K}_4\text{Fe}(\text{CN})_6$  pptd. with  $\text{Pb}(\text{NO}_3)_2$ , the filtered solution can be titrated with  $\text{AgNO}_3$ .  $\text{K}_3\text{Fe}(\text{CN})_6$  and  $\text{KCNS}$  can be titrated consecutively,  $\text{AgCNS}$  being pptd. before the  $\text{Ag}_3\text{Fe}(\text{CN})_6$ . The solubility of  $\text{Ag}_3\text{Fe}(\text{CN})_6$  was calc. as  $4 \times 10^{-5}N$ , and the solubility product  $[\text{Ag}^+]^3 \times [\text{Fe}(\text{CN})_6^{3-}]$  as  $8.4 \times 10^{-19}N$ .

C. R. H.

Potentiometric determination of cobalt and manganese.—See B., 1936, 840.

Electroanalysis and macro-electroanalysis of nickel with three electrodes. J. GUZMAN and G. GARCÍA (Anal. Fis. Quím., 1934, 32, 923—930).—

Guzman's method is applied successfully to  $\text{NH}_3$ -Ni solutions containing  $\text{PO}_4^{3-}$ ,  $\text{BO}_3^{3-}$ ,  $\text{HCO}_3^-$ ,  $\text{OAc}^-$ , and  $\text{C}_2\text{O}_4^{2-}$ . Anodes of passive Fe and cathodes of brass may be employed.

D. R. D.

Determination of chromium.—See B., 1936, 744, 839, 840.

Mechanism of the benzidine reaction for chromium. L. KÜHLBERG (Mikrochem., 1936, 20, 244—246).—The sensitivity of the benzidine-blue test for  $\text{Cr}_2\text{O}_7^{2-}$  is increased by addition of  $\text{H}_2\text{O}_2$ . Greater sensitivity is attained with *o*-tolidine +  $\text{H}_2\text{O}_2$ . Possible mechanisms are discussed.

R. S.

Separation and determination of tungsten and molybdenum. H. YAGODA and H. A. FALES (J. Amer. Chem. Soc., 1936, 58, 1494—1501).— $\text{MoS}_3$  can be pptd. quantitatively in aq. solution in presence of  $\text{HCO}_2\text{H}$  by reaction with saturated aq.  $\text{H}_2\text{S}$  at 0°. Separation from W is effected by adjusting the  $p_H$  to 2.9 by means of a buffer mixture of  $\text{HCO}_2\text{NH}_4$ , tartaric acid, and  $\text{HCO}_2\text{H}$ .

E. S. H.

Separation of small amounts of tin in presence of antimony and arsenic. N. J. TSCHERVIAKOV and E. A. OSTROUMOV (Ann. Chim. Analyt., 1936, [iii], 18, 201—207).—Sn, Sb, and As are separated from Cu, Bi, etc. by pptn. with  $\text{Na}_2\text{S}$ , and are repptd. from the solution by addition of  $\text{AcOH}$ . The sulphides are dissolved in *N*- $\text{HCl}$  at 30—40°, and Sn is pptd. by a large excess of cupferron at > 5°.

J. S. A.

Colorimetric determination of germanium. I. P. ALIMARIN and B. N. IVANOV-EMIN (J. Appl. Chem. Russ., 1936, 9, 1334—1339).—The distillate obtained by heating the mineral in a stream of  $\text{Cl}_2$  is decolorised by aq.  $\text{NaHSO}_3$ , a small excess of Br is added, and the solution is again made colourless with  $\text{NaHSO}_3$ . The  $[\text{HCl}]$  is adjusted to 6N,  $\text{H}_2\text{S}$  is passed, and the ppt. is collected after 24 hr., washed, and dissolved in 1%  $\text{NaOH}$ . The solution is heated with  $\text{H}_2\text{O}_2$ , excess of which is decomposed by boiling, and  $\text{H}_2\text{O}$  is added to a known vol. 5%  $(\text{NH}_4)_2\text{MoO}_4$  and  $\text{HNO}_3$  to 0.15—0.35N are added to a portion of solution, the vol. is made up to 25—50 ml., and the yellow coloration is compared with that given by a standard solution, or with aq. picric acid (I) [10 mg. of (I) per litre correspond with 7.48 mg. of  $\text{GeO}_2$  per 100 ml.]. The method permits the determination of 1 p.p.m. of Ge. Org. acids, Se, F',  $\text{PO}_4^{3-}$ , and  $\text{SiO}_3^{2-}$  interfere, as does also  $\text{As}^V$  when present in large amount.

R. T.

Determination of vanadium in the field. A. S. KOMAROVSKI (Mikrochem., 1936, 20, 161—162).—The method of Tananaev and Pantschenko, as described by Silbermintz and Florenzki (A., 1935, 1474), is inapplicable in presence of  $\text{CrO}_4^{2-}$ ,  $\text{ClO}_3^-$ ,  $\text{MnO}_4^-$ , etc.

R. S.

Determination of antimony in copper.—See B., 1936, 889.

Determination of gold with gaseous hydrogen phosphide and filter-paper. N. D. COSTEANU (Bull. Soc. chim., 1936, [v], 3, 1527—1530).—A filter-paper soaked in aq.  $\text{AuCl}_3$  and then exposed to  $\text{PH}_3$  turns dark blue, owing to production of colloidal Au.

The intensity of coloration  $\propto$  the [Au] of the solution, and can be compared with standards. 25-mg. test samples only are required for determination of Au in jewellery etc. J. W. S.

Detection of small amounts of platinum in minerals, alloys, precipitates, etc. Separation and concentration of platinum by precipitation with tellurium. S. K. HAGEN (Mikrochem., 1936, 20, 180—188).—The alkaline solution is treated with KI and AcOH. A reddish-brown or rose colour appears if Pt<sup>++++</sup> is present. Te, pptd. from solutions containing NaTeO<sub>2</sub> by treatment with SO<sub>2</sub>, separates Pt, Au, Se, Mo, and Hg from the other metals. Pt may then be detected as above. R. S.

Precision thermostat for the temperature regulation of a room. T. DEIGHTON (J. Sci. Instr., 1936, 13, 298—300).—Two connected expansion chambers control a heater of very small heat capacity. One is controlled by the room temp. and the other by the heater itself, thus taking up the lag at once. Temp. variation is  $< 0.01^\circ$ . C. W. G.

Simplified and accurate process for the calculation of heat loss in calorimetric determinations. H. MOSER (Physikal., 1936, 37, 529—533).—A method of determining the heat loss during the course of a calorimetric experiment involves the use of the Regnault-Pfaundler formula instead of the more usual, but less accurate, Langbein formula. A. J. M.

Cryogenic laboratory of the California Institute of Technology. II. A. GOETZ (Rev. Sci. Instr., 1936, [ii], 7, 307—318; cf. A., 1935, 1212).—A description is given of the He liquefaction plant, separate "stations" for particular types of experiments, details of the station for X-ray spectroscopy at low temp., and equipment for potentiometric measurements. N. M. B.

Photo-electric colorimeter. I. M. DILLER (J. Biol. Chem., 1936, 115, 315—322). H. D.

Stabilised photo-electric colorimeter with light filters. K. A. EVELYN (J. Biol. Chem., 1936, 115, 63—75).—The construction of a direct-reading, single photo-cell colorimeter of exceptional stability is described. H. G. R.

Photo-electric colorimeter for determining carbon dioxide in air.—Sec B., 1936, 861.

Spectropolarimeter for the Schumann region. R. SERVANT (Compt. rend., 1936, 203, 311—312).—The apparatus previously described has been modified to permit the use of lower  $\lambda\lambda$  (cf. this vol., 697). C. R. H.

Optical difficulties with the cylindrical cataphoresis cell. A. M. BUSWELL and T. E. LARSON (J. Physical Chem., 1936, 40, 833—834).—To obtain illumination at the correct depth in the Mattson cell (A., 1933, 349) the light beam should enter the liquid at a depth of  $0.377R$  from the top, where  $R$  is the radius of the cell. J. W. S.

Ultra-violet solution light filters. W. V. BHAGWAT (Bull. Acad. Sci. U.P., 1932, 2, 67—74).—Aq. CoCl<sub>2</sub> (3.66 mol.) + Ni(NO<sub>3</sub>)<sub>2</sub> (2.08 mol.) transmits

$\lambda\lambda$  3307—3598 Å.; aq. CoCl<sub>2</sub> (3.66 mol.) transmits  $\lambda\lambda$  2618—4063 and 7100—7600 Å. CH. ABS. (e)

Investigation of Raman spectra by means of a photo-electric counter. V. KUDRJAVEVA (Acta Physicochim. U.R.S.S., 1935, 3, 613—618).—Apparatus, consisting essentially of a photo-electric counter placed behind the second slit of a monochromator, enables the dependence of the intensity of the scattered light on  $\lambda$  to be determined. It can also be used for measuring the relative intensity and change in intensity of single Raman lines. C. R. H.

Technique of photographic spectrophotometry of solutions. H. VON HALBAN, G. KORTUM, and B. SZIGETI (Z. Elektrochem., 1936, 42, 628—631).—Modified technique is described. E. S. H.

Sputtering of large-aperture Fabry-Perot interferometer mirrors. S. TOLANSKY and E. LEE (J. Sci. Instr., 1936, 13, 261—263).—Directions for obtaining deposits of large area, uniform thickness, and high reflecting power are given. C. W. G.

Continuous absorption spectra: experimental methods. R. G. AICKIN (J. Proc. Austral. Chem. Inst., 1936, 3, 206—212).—A review.

Measurement of optical densities of smoke stains on filter-papers. A. S. G. HILL (Trans. Faraday Soc., 1936, 32, 1125—1131).—A photo-electric cell method is described. J. G. A. G.

Apparatus for preparing microphotometer records of electron diffraction photographs. C. DEGARD and W. VAN DER GRINTEN (Rev. Sci. Instr., 1936, [ii], 7, 319).—An arrangement is described for rotating the plate at 600—1000 r.p.m. while the record is being made; this obviates emulsion grain and dust effects and gives a fine smooth curve. N. M. B.

Correction of gas refractometer reading for temperature and pressure change. Z. TUZI and H. OOSIMA (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 718—729).—The correction for temp. and pressure of the gas refractometer, used as an indicator of explosive gas, is calc., and agrees with experimental results. R. S. B.

Objective microphotometry. P. KRUMHOLZ (Mikrochem., 1936, 20, 227—235).—A microphotometer in which 1 c.c. of solution can be tested is described. Standard absorption curves for blue, green, and yellow filters are given. R. S.

Combined transparent photo-cathodes. P. GORLICH (Z. Physik, 1936, 101, 335—342).—Cs alloys are used to give transparent red-sensitive photo-cathodes; the long- $\lambda$  limit can be extended by sensitisation with O<sub>2</sub>. The quantum efficiency is large when the second alloy component is Bi or Sb. A. B. D. C.

Apparatus for spectroscopic chemical analysis. J. L. GRING and G. L. CLARK (Rev. Sci. Instr., 1936, [ii], 7, 305—306).—An electrode stand holding four pairs of electrodes simultaneously, and an improved apparatus for producing an under-water spark, are described. N. M. B.

Machine for drawing pole-figures directly from X-ray diffraction patterns. D. McLACHLAN, jun.

(Rev. Sci. Instr., 1936, [ii], 7, 301—304).—The construction and use of a simple instrument for drawing stereographic pole figures are described. N. M. B.

**Ultrasonic stroboscope.** E. HIEDEMANN and K. H. HOESCH (Z. Physik, 1936, 102, 253—258).—Ultrasonic stroboscopes may be constructed employing the following principles: the production of artificial double refraction in substances by ultrasonic waves, and the modulation of light by such waves. Several stroboscopes are described, and their use is demonstrated. A. J. M.

**Simplifications in step and inversion potentiometers.** J. GUZMAN and A. ARA (Anal. Fis. Quím., 1934, 32, 1067—1076).—Zn, Al, Sb, Cu, Ag, Hg, Au, Pd, or Pt in  $N\text{-KCl}$  or  $\text{-K}_2\text{SO}_4$  is used as intermediate electrode. D. R. D.

**Graduated electrical resistances.** J. GUZMAN (Anal. Fis. Quím., 1934, 32, 918—922).—Simple resistances for use in potentiometry are described. D. R. D.

**Emanation electroscope.** B. A. SPICER (J. Sci. Instr., 1936, 13, 263—267).—The ionising effect of  $\beta$ -rays is used, and 0.001—3.0 millicuries of Rn can be measured. C. W. G.

**Double amplifying apparatus for the detection of individual electrons in thermal emission.** E. H. WINKLER (Physikal. Z., 1936, 37, 557—558). A. J. M.

**Primary and secondary image in the electron microscope.** II. Investigation of structure by electron diffusion. H. BOERSCH (Ann. Physik, 1936, [v], 27, 75—80; cf. *ibid.*, 26, 631).—A method whereby the crystal structure of small selected areas of the object can be investigated in the electron microscope is described. O. D. S.

**Second-order focussing for the mass spectrograph.** W. W. SAWYER (Proc. Camb. Phil. Soc., 1936, 32, 453—460).—Mathematical. Conditions are calc. for the lay-out of a mass spectrograph with second-order focussing. O. D. S.

**Speed control for small direct-current motors.** L. G. HOXTON (Science, 1936, 84, 187—188). L. S. T.

**Wilson cloud-chamber of simple construction.** H. NEUERT (Physikal. Z., 1936, 37, 629—630).—Details are given for constructing a simple, portable cloud-chamber. A. J. M.

**Simple Wilson cloud-chamber.** H. BAUER (Physikal. Z., 1936, 37, 627—629).—The apparatus is described. A 50%  $\text{EtOH-H}_2\text{O}$  mixture is recommended for the chamber liquid. A. J. M.

**Stability of standard cells.** P. VIGOREUX (J. Sci. Instr., 1936, 13, 297—298).—Temp. variation from  $-8^\circ$  to  $60^\circ$  does not affect the e.m.f. of Cd cells containing acid, provided constant temp. is maintained just before and during measurement. C. W. G.

**Photo-electric methods of measuring the velocity of rapid reactions.** I. General principles and controls. F. J. W. ROUGHTON and G. A. MILLIKAN. II. Simple apparatus for rapid  $p_{\text{H}}$  and other changes requiring 200 c.c. or more of each reagent. F. J. W. ROUGHTON. III.

**Portable micro-apparatus applicable to an extended range of reactions.** G. A. MILLIKAN (Proc. Roy. Soc., 1936, A, 155, 258—269, 269—276, 277—291).—I. An optical method of analysis of the moving fluid has been devised in the Hartridge-Roughton rapid reaction apparatus, rendering it more economical in the use of fluid. This is accomplished by the use of photo-electric cells. More accurate and extensive tests of the efficiency of mixing and character of flow down the observation tube have been made.

II. A photo-electric method for analysing the colour of the streaming fluid in various parts of the observation tube is described. The method has been applied to the colour changes of indicators, and rapid  $p_{\text{H}}$  changes may be followed. Under good conditions an accuracy of 0.01—0.02  $p_{\text{H}}$  is obtained. The method is used for the determination of the velocity coeffs. of the reaction (1)  $\text{H}_2\text{CO}_3 \rightarrow \text{CO}_2 + \text{H}_2\text{O}$  and (2)  $\text{CO}_2 + \text{OH}' \rightarrow \text{HCO}_3'$ , and the vals. obtained agree with those given by other methods.

III. The continuous-flow apparatus has been modified to adapt it for reactions involving any kind of colour change, small quantities of material, and easy transport. It is proved to be adequate to deal with processes the half reaction time of which is  $>0.0005$  sec. L. L. B.

**Contact potential difference.** C. W. OATLEY (Proc. Roy. Soc., 1936, A, 155, 218—234).—Details are given of a new method of measuring contact p.d., which depends on the known relation between anode voltage and crit. magnetic field in a magnetron, when electrons from the filament just fail to reach the anode. The method enables the contact potential of a given surface to be measured with respect to a hot W filament. Results are given for Zn and Mo surfaces. L. L. B.

**U-Tube method of measuring electrophoresis.** A. L. ROBERTS and J. C. CARRUTHERS (J. Physical Chem., 1936, 40, 703—708).—Measurements made by the U-tube method, uncorr. for the electro-osmotic flow of the medium, agree satisfactorily with those made by the microscopic cell method where such corrections must be introduced. J. W. S.

**Electro-osmotic measurements.** A. VAŠIČEK (Chem. Listy, 1936, 30, 173—175).—Apparatus and methods are described. R. T.

**Determination of the Curie point of ferromagnetic substances.** L. BERGMANN (Physikal. Z., 1936, 37, 547—548).—A hollow cylinder of the material under investigation carries a thermo-couple and is placed in a double coil. One coil magnetises the specimen, whilst the other is connected to a low-frequency amplifier. The specimen is heated above the Curie point, and allowed to cool in the apparatus while it is intermittently heated by focussing on it the rays from a small arc lamp. When the sample cools to the Curie point the intermittent heating causes variations in the magnetisation which are observed by means of the amplifier. The val. obtained for Ni was  $345^\circ$ , and for monel metal  $110^\circ$ . A. J. M.

**Automatic titration burette.** E. BAYER (Chem.-Ztg., 1936, 60, 726). J. S. A.

**Macro-micro-burette and precision micro-pipette.** J. GUZMAN (Anal. Fis. Quím., 1934, 32, 1129—1134).—A macro-micro-burette and precision micro-pipette suitable for electrometric titration are described.  
L. A. O'N.

**Absorber of CO<sub>2</sub> for currents of atmospheric air.** A. A. RICHTER (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 291—293; cf. A., 1902, ii, 682).—The air is forced through a pressed glass filter into a glass tower containing 0.02*N*-NaOH and 2—5 drops of BuOH; this yields an intense foam with a very large absorptive surface. Reproducible results are obtained if the current has a speed of 30—40 litres per hr.  
R. C. M.

**Separation of gaseous isotopes by diffusion.** D. E. WOOLDRIDGE and W. R. SMYTHE (Physical Rev., 1936, [ii], 50, 233—237).—The design, use, and results of tests with a 34-member Hertzian type apparatus are described. Marked enrichments of <sup>13</sup>C<sup>1</sup>H<sub>4</sub> from CH<sub>4</sub> and <sup>15</sup>N from N<sub>2</sub> were obtained (cf. this vol., 574, 772).  
N. M. B.

**Dilatometer for wide range of temperature.** H. SCHLÜTER (Chem.-Ztg., 1936, 60, 717).  
J. S. A.

**Apparatus for determination of the apparent volume and of the volume of voids.**—See B., 1936, 769.

**Method of measuring the net density of a substance which dissolves a little in a liquid.** U. YOSHIDA, S. MATANO, and M. WATANABE (Mem. Coll. Sci. Kyoto, 1936, 19, 161—168).—The following wts. are determined: a sealed evacuated tube containing the specimen, the tube filled with a liquid of known *d*, the tube alone. From these data and the vol. of the sealed tube the *d* of the solid can be calc.  
C. W. G.

**Accurate pycnometer.** J. M. CLAVERA and F. MORENO MARTIN (Anal. Fis. Quím., 1934, 32, 690—697).—A pycnometer and apparatus for filling are described.  
L. A. O'N.

**Rotary dialyser of large capacity.** G. FLORENCE and D. VINCENT (Bull. Soc. Chim. biol., 1936, 18, 1167—1169).  
A. L.

**Pouring from vessels.** H. KEIM (Chem.-Ztg., 1936, 60, 664).—The glass rod, used as an aid in pouring from beakers etc., is bent at an angle of 45° about 1 cm. from its end.  
E. S. H.

**Active hydrogen, oxygen, and nitrogen at pressures up to 20 mm.** P. HARTECK [with E. ROEDER] (Z. Elektrochem., 1936, 42, 536—538).—Apparatus and procedure for activating H<sub>2</sub>, O<sub>2</sub>, and N<sub>2</sub> at higher pressures than heretofore are described.

Preliminary observations on reduction and oxidation reactions are reported.  
E. S. H.

**Volumetric adsorption methods.** F. DURAU (Z. Physik, 1936, 101, 27—67).—Errors due to temp., pressure, adsorption by glass walls, solubility of the adsorptive in grease, vol. changes due to compression by the atm., and deviations from the gas laws have been empirically determined. The volumetric method is also developed for use with org. vapours.  
A. B. D. C.

**Hydrogen sulphide apparatus.** F. MORENO MARTIN (Anal. Fis. Quím., 1934, 32, 891—892).—A delivery tube terminating in a hook carrying a porous porcelain basket containing sulphide passes through the mouth of a bell jar which is placed inside a slightly wider jar of acid.  
F. R. G.

**Apparatus for obtaining hydrogen sulphide.** F. E. RAURICH SAS (Anal. Fis. Quím., 1934, 32, 1007—1010).—A large apparatus for the prep. and storage of H<sub>2</sub>S is described.  
D. R. D.

**Apparatus for distillation.** H. I. COOMBS (Biochem. J., 1936, 30, 1586—1587).—The apparatus is made of Pyrex, and is suitable for the distillation of conc. acids.  
F. A. A.

**Apparatus for fractional vacuum distillation of small amounts of high-boiling mixtures.** E. KLENK (Z. physiol. Chem., 1936, 242, 250—252).—The apparatus described is especially suitable for distillation of <0.5 g. of high-boiling fatty acids and their esters.  
W. McC.

**Fractional distillation columns.**—See B., 1936, 768, 819.

**Plastics in instrument design.** H. W. ROWELL (J. Sci. Instr., 1936, 13, 277—282).—Many applications are described, together with information as to methods of working.  
C. W. G.

**Production of metallic films.** R. V. JONES (J. Sci. Instr., 1936, 13, 282—288).—A method of preparing metal foil 0.1 μ thick by rolling is described. The electrical properties of rolled foil are superior to those of samples prepared by other methods.  
C. W. G.

**Motor-driven circulating pump.** G. BARR (J. Sci. Instr., 1936, 13, 300—302).—A glass bell is raised and lowered through a Hg seal, and, dipping continuously in Hg in a vessel in which it is itself enclosed, circulates gas through valves by double action.  
C. W. G.

**Lecture experiment in combustion chemistry.** H. ULICH (Angew. Chem., 1936, 49, 619—620).—The experiment demonstrates the influence of pressure on the reaction of H<sub>2</sub> with O<sub>2</sub>.  
E. S. H.

## Geochemistry.

**Variations in the atmospheric dust content due to micro-atmospheric influences.** R. MELBAU (Trans. Faraday Soc., 1936, 32, 1270—1272).—Very small (micro-atm.) differences of temp., humidity, and of air currents lead to high concns. of fog and dust at unexpected places.  
J. G. A. G.

**Influence of urban conditions on the circulation of electricity through the atmosphere.** F. J. W. WHIPPLE (Trans. Faraday Soc., 1936, 32, 1203—1209).—Diurnal variations of the resistance of the atm. are correlated with the formation of ions and smoke from the combustion of fuel.  
J. G. A. G.

**Fog along the Meuse valley.** J. FIRKET (Trans. Faraday Soc., 1936, 32, 1192—1196).—A summary of the scientific report on the fog disaster of Dec. 1—5, 1930; toxic effects are attributed to  $\text{SO}_2$  and  $\text{SO}_3$ .

J. G. A. G.

**Emanation content of hot springs and artesian wells in the Peiping area.** Y. K. HSU and Y. M. HSIEH (Chinese J. Physics, 1936, 2, 106—116).—The Th- and Ra-emanation contents of a no. of hot springs and artesian wells have been measured.

O. D. S.

**Geological significance of thermophilic bacteria.** A. SCHLOEMER (Chem. Erde, 1936, 10, 667—670).—Sinter deposited by the agency of bacteria in the hot ( $40$ — $50^\circ$ ) springs at Aachen contains  $\text{CaCO}_3$  61.35,  $\text{SiO}_2$  29.74,  $\text{Fe}_2\text{O}_3$  3.15%. Sinter deposited by the hotter ( $60$ — $70^\circ$ ) springs in the Burtscheid suburb contains  $\text{CaCO}_3$  99.82%.

L. J. S.

**Chemical characteristics of some Jugoslavian lakes.** K. HOLL (Arch. Hydrobiol., 1935, 28, 437—442; Chem. Zentr., 1935, ii, 3493).—Analytical data are recorded.

J. S. A.

**Mineral water from the Graf Ludwigstorff iodine-sulphur spring at Bad Deutsch-Altenburg.** J. GANGL and R. POSEGA (Wien. klin. Woch., 1935, 48, 1157—1160).—Analyses are recorded.

H. J. E.

**Analyses of mineral water of Marano Equo [Italy].** A. FOSCHINI and B. ROSSI (Annali Chim. Appl., 1936, 26, 270—282).—Data are given for inorg. and gaseous constituents, radioactivity, and physico-chemical consts.

F. O. H.

**Enrichment of heavy water in glacier ice and melting diagram of system  $\text{H}_2\text{O}$ — $\text{D}_2\text{O}$ .** A. EUCKEN and K. SCHAFER (Nachr. Ges. Wiss. Göttingen, 1935, [ii], 1, 109—125; Chem. Zentr., 1935, ii, 3741).—The enrichment of  $\text{D}_2\text{O}$  in glacier ice is the greater the smaller is the amount of the original ice remaining—e.g., in the narrow pointed tongues of deep valley glaciers with large basins—and may attain 50%. The m.p. diagram of the system  $\text{D}_2\text{O}$ — $\text{HDO}$ — $\text{H}_2\text{O}$  is calc. from the m.p. and latent heats,  $L$ , on the assumption that  $L/T$  rises regularly from  $\text{H}_2\text{O}$  to  $\text{D}_2\text{O}$ . The m.p. of  $\text{HDO}$  is extrapolated from the m.p. of  $\text{H}_2\text{O}$  low in D as  $2.50^\circ$ . The enrichment of  $\text{D}_2\text{O}$  in the solid phase is calc. and compared with experimental vals.

J. S. A.

**Gas occurrence in southern Daghestan.** J. G. IVASCHTSCHENKO and E. A. PODALKO (Azer. Neft. Choz., 1934, No. 11—12, 38—44).—Analyses are given.

CH. ABS. (e)

**Natural gases in Azerbaidshan.** L. POTOLOVSKI and V. BUINITZKAJA (Azer. Neft. Choz., 1934, No. 11—12, 25—28).—Five types of gas occur: (1)  $\text{CH}_4$  with little  $\text{CO}_2$  and  $\text{N}_2$  and traces of He; (2)  $\text{CH}_4$  with  $> 43\%$   $\text{N}_2$ ,  $> 0.15\%$  He, and some  $\text{CO}_2$ ; (3)  $\text{CH}_4$  and  $\text{N}_2$  with 9—30%  $\text{CO}_2$  and considerable He; (4)  $\text{N}_2$ , with considerable He; (5)  $\text{CO}_2$ .

CH. ABS. (e)

**Application of  $VEK$  in geochemistry.** A. E. FERSMAN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 393—396; cf. A., 1935, 1305).—Since  $VEK$  (amount of energy, per unit valency, released by an

ion in forming a heterovalent or at. crystal lattice) should (theoretically) decrease, for cations and anions, with increasing alkalinity or acidity, respectively, it should be a useful measure of these properties; tabulated vals. of  $VEK$  in general support this argument (those for cations being compared with the pptn.  $\mu_n$ ) except in the case of cations from subsidiary groups in the periodic table. Possible geochemical applications are outlined. R. C. M.

**Electrical conductivity of rocks.** (MME.) F. BAYARD-DUCLAUX (Ann. Physique, 1936, [xi], 6, 5—107).—Data obtained by using a Wheatstone bridge method, the specimen being held at various high pressures between two metallic electrodes, are given for a no. of rocks from various localities. Results are reported for a study of the variation of resistance with p.d., time of passage of current, temp., and state of desiccation of the specimen, and for the effect of saturating the specimens with distilled or salt  $\text{H}_2\text{O}$ , and for the humidity of the surrounding air. The electrolytic conductivity of specimens between electrolytes as anode and cathode is described, and theoretical considerations are discussed.

N. M. B.

**Lattice of uraninite.** A. SCHOEP and V. BILLIET (Bull. Soc. géol. Belg., 1935, 58, 198—206; Chem. Zentr., 1935, ii, 3491—3492).—Uraninite from both Shinkolobere and Katanga is identical with synthetic  $\text{UO}_2$ . The face-centred cubic lattice has  $a$  5.47 Å.

J. S. A.

**Crystalline uraninite from Kasolo-Shinkolobwe.** R. VAN AUBEL (Publ. Congo belge, 1934—1935, 42—48).—The length of the edge of the unit cube was 4.67 Å. Elements detected spectroscopically are recorded.

H. J. E.

**Radioactivity of bituminous shale.** I. N. A. ORLOV and L. M. KURBATOV (Chim. Tverd. Topl., 1934, 5, 525—527).—The  $\text{U}_3\text{O}_8$  content of samples from a deposit near the river Popovka was 0.21% (deduced from the  $\alpha$ -activity). In an  $\text{HCl}$  extract the Ra content was  $16.5 \times 10^{-12}$  g. per g. of shale. The Th was  $12.5 \times 10^{-5}$  g. per g. of shale.

CH. ABS. (e)

**Determination of the gas content of horizons by the radioactivity of the minerals.** A. SNARSKI (Azer. Neft. Choz., 1934, No. 11—12, 28—34).—A review.

CH. ABS. (e)

**Significance of quantitative microanalyses of radioactive minerals for measurement of geological time.** F. HECHT and E. KROUPA (Z. anal. Chem., 1936, 106, 82—103).—Results are recorded for complete microanalyses of uraninites, pitchblendes, thorianite, monazite, and allanites, using 20—40 mg. of hand-picked material or a single crystal for each analysis. Good agreement of the U : Pb ratio with that determined macroanalytically shows the applicability of rock microanalysis to the determination of geological age.

J. S. A.

**Pleochroic (radioactive) haloes, their distribution in rocks and variability.** M. STARK (Chem. Erde, 1936, 10, 566—630).—The minerals composing rocks of all kinds and of different geological ages were examined for pleochroic haloes. These

are not always present, and they are affected by changes in the rocks. They do not afford a trustworthy indication of the age of a rock, but they give some idea of the distribution of radioactive elements.

L. J. S.

**Melilite-basalt from Westberg [Hesse-Nassau], an assimilation product of ultrabasic rocks.** T. ERNST (Chem. Erde, 1936, 10, 631—666).—Nodules of olivine and pyroxene present in this rock are relics of fragments of ultrabasic rocks brought up with the magma from depth: they are not segregation products as previously thought. Analyses are given of the rock and of the pyroxene, and the composition of the original magma is calc. The composition appears to have been only slightly affected by the assimilation of sedimentary rocks into which the magma was intruded.

L. J. S.

**Origin of the Passau [Bavaria] graphite deposits.** A. MAUCHER (Chem. Erde, 1936, 10, 539—565).—The presence of V, up to 0.1% (together with Ni, Co, Cu, Cr), is taken to indicate that the graphite is of org., probably algal, origin (like the bitumen of the Black Sea), with subsequent profound modification by metamorphic processes.

L. J. S.

**Origin of quartz in the Bavarian Pfahl.** F. HEGEMANN (Chem. Erde, 1936, 10, 521—538).—The large bodies of massive quartz ( $\text{SiO}_2$  95–11%) present in this zone of dislocation are of hydrothermal origin.

L. J. S.

**Arsenic in Upper Carboniferous and Permian sediments in Silesia and Bohemia.** K. HOEHNE and W. E. PETRASCHECK (Chem. Erde, 1936, 10, 475—478).—Ironstones and shales contain 0.1–0.74%  $\text{As}_2\text{O}_5$ , the larger amounts being from localities nearer the Riesengebirge granite mass (whence the As was derived), and in materials richer in Fe and C.

L. J. S.

**Mineral paragenesis of gravel ores in Outokumpu and Polvijärvi districts.** H. VAYRYNEN (Bull. Comm. géol. Finlande, 1935, No. 109, 19 pp.; Chem. Zentr., 1935, ii, 3492).—The Outokumpu deposits probably originated above the crit. temp. of the  $\text{H}_2\text{O}$  solutions, but below the equilibrium temp. of the reaction  $\text{CaCO}_3 + \text{SiO}_2 = \text{CaSiO}_3 + \text{CO}_2$ . Polvijärvi deposits originated under hydrothermal conditions not much above 400°.

J. S. A.

**Blockite, a new selenium ore from Bolivia.** R. HERZENBERG and F. AHLFELD (Zentr. Min., 1935, A, 277—279; Chem. Zentr., 1935, ii, 3492).—A mineral approximating to  $(\text{Ni,Cu})\text{Se}_2$  is described.

J. S. A.

**Coprolites from North African phosphates.** L. CAYEUX (Compt. rend., 1936, 203, 217—219).—These coprolites consist of  $\text{Ca}_3(\text{PO}_4)_2$  and have no action on polarised light. They are free from mineral or org. inclusions.

J. W. S.

**Characteristics of the activity and the peculiar product "sara-isi" of the Aso volcano.** M. NAMBA (Mem. Coll. Sci. Kyoto, 1936, 19, 131—159).—Analyses are given.

C. W. G.

**Romerite from Pfaffenreuth, Obpf.** B. GOSNER and K. DREXLER (Zentr. Min., 1935, A, 267—270).—The composition is  $\text{SO}_3$  38.40,  $\text{Fe}_2\text{O}_3$  19.55,

$\text{Al}_2\text{O}_3$  1.4,  $\text{FeO}$  0.78,  $\text{MgO}$  0.14,  $\text{CaO}$  0.62,  $\text{H}_2\text{O}$  31.17%.

H. J. E.

**Lithiferous pegmatite from Goyás (Lalin).** I. PARGA-PONDAL and M. DE LA E. FRAGA-PADIN (Anal. Fis. Quím., 1934, 32, 1011—1020).—The pegmatite is a mixture containing albite (53%), spodumene (22%), quartz (19%), and small proportions of orthoclase, muscovite, anorthite, and magnetite. The pegmatite contains 1.20%  $\text{Li}_2\text{O}$ , present entirely in the spodumene ( $\text{Li}_2\text{O}$  5.55%). Complete analyses of the pegmatite, spodumene, and muscovite are given.

D. R. D.

**Kasolite.** V. BILLIET and W. F. DE JONG (Natuurwetensch. Tijds., 1936, 18, 261—265).—X-Ray and chemical examination show that kasolite,  $\text{PbO} \cdot \text{UO}_3 \cdot \text{SiO}_2 \cdot \text{H}_2\text{O}$ ,  $d$  6.46, forms monoclinic crystals,  $a : b : c = 1.8953 : 1 : 0.9575$ ,  $\beta = 75^\circ 18'$ .

S. C.

**Crystalline chalky rocks of Kivu.** J. THOREAU (Bull. Acad. roy. Belg., 1936, [v], 22, 753—757).—A description and results of analyses [RONCHESNE] of some of these rocks are given.

D. C. J.

**Behaviour of coloured agates in ultra-violet light.** K. OBENAUER (Deut. Golschmiede-Ztg., 1935, 38, 384—385; Chem. Zentr., 1935, ii, 3644).—Agates dyed with org. dyes fluoresce brightly; those coloured with metal compounds, and also true lapis lazuli, are not fluorescent.

J. S. A.

**Origin of tektite surfaces.** V. ROSICKY (Zentr. Min., 1935, A, 270—277; Chem. Zentr., 1935, ii, 3644).—The surface formations are attributed to chemical corrosion after reaching the earth.

J. S. A.

**Olivine lumps of basalt as fragments of older olivine rocks.** T. ERNST (Nachr. Ges. Wiss. Göttingen, Math.-phys. Kl., 1935, [ii], 1, 147—154; Chem. Zentr., 1935, ii, 3644).—Petrographic evidence is advanced.

J. S. A.

**Paragenetic relations and mode of formation of minerals and pseudomorphs of the Wendelstein range, Nürnberg.** S. KLEIN (Zentr. Min., 1935, A, 231—242; Chem. Zentr., 1935, ii, 3644).—Petrographic data are given for minerals from the arkose layers from the Frankish keuper deposits.

J. S. A.

**Micro-plankton in the phosphates of Tunis and eastern Algeria.** L. CAYEUX (Compt. rend., 1936, 203, 477—480).—A systematic study of the numerous diatoms found in phosphate grains in the main beds of the above localities has been made.

D. C. J.

**Relations of bodies of the sepiolite-attapulgite series to the phyllic silicates of the mica type.** J. DE LAPPARENT (Compt. rend., 1936, 203, 482—484).—Data have been collected in support of the above relation.

D. C. J.

**Sepiolites.** H. LONGCHAMON and G. MICEON (Compt. rend., 1936, 203, 431—433).—Examination of three further samples of fibrous texture visible to the unaided eye confirms the composition and structure described previously (A., 1935, 842, 1099). The interpretation proposed by de Lapparent (this vol., 957), attributing to them a phyllite structure, is criticised.

J. W. S.

**Meteoric iron from the province of Granada.** J. DORRONSORO and F. MORENO MARTÍN (Anal. Fis. Quim., 1934, **32**, 1111—1115).—A meteorite weighing 134 g. contained Fe 91.500, Ni 7.162, Co 0.426,  $\text{SiO}_2$  0.645, S 0.127, C 0.122, P 0.028%, and traces of Mg, Ge, and Ag. D. R. D.

**Magnetite deposit near Humacao, Puerto Rico.** R. J. COLONY and H. A. MAYERHOFF (Trans. Amer. Inst. Min. Met. Eng., 1935, **115**, 247—272).—The magnetite is directly associated with andesitic and dioritic intrusions. It is of contact replacement origin. Analyses and petrographic data are given.

CH. ABS. (e)

**Iron ores of Hunan.** C. C. TIEN, H. C. WANG, and T. Y. LIU (Geol. Survey Hunan, 1934, Mem. Ser., A, **1**, 124 pp.).—The ores are described. Analyses are given.

CH. ABS. (e)

**Origin of Siegerland spathic iron ore veins by lateral secretion.** H. BREDDIN (Glückauf, 1935, **71**, 821—830; Chem. Zentr., 1935, ii, 3492).—The veins are considered to be derived by aq. deposition from  $\text{FeCO}_3$  in neighbouring rocks, from which thermal  $\text{H}_2\text{O}$  was expelled during pressure metamorphism.

J. S. A.

**Optical properties, densities, and degree of corrosion of the alumino-magnesian titanomagnetites.** G. JOURAVSKY (Compt. rend., 1936, **203**, 373—375; cf. this vol., 1089).—The reflective power and  $d$  diminish whilst the velocity of corrosion by HCl increases with increase of Fe content. R. S.

**Dickite from St. Louis County, Missouri.** V. T. ALLEN (Amer. Min., 1936, **21**, 457—459).

L. S. T.

**Mineral formation in system  $\text{Al}_2\text{O}_3$ - $\text{SiO}_2$ - $\text{H}_2\text{O}$ .** W. NOLL (Jahrb. Min. Beil.-Bd., 1935, A, **70**, 65—115; Chem. Zentr., 1935, ii, 3368; cf. this vol., 584).—No reaction takes place between  $\text{Al}_2\text{O}_3$  and  $\text{SiO}_2$  in adsorption mixtures at room temp., but under hydrothermal conditions reaction is rapid. Cryst. phases formed are bohmite (I); bayerite,  $\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$  (unstable); corundum (II); kaolin; a pyrophyllite  $\text{Al}_2\text{O}_3 \cdot 4\text{SiO}_2 \cdot \text{H}_2\text{O}$  (III); montmorillonite and an Al silicate (IV), described by Schlapfer and Niggli, probably a sillimanite.  $\text{SiO}_2$  remains amorphous at all temp. Kaolin is formed at  $<400^\circ$ , with all ratios of  $\text{Al}_2\text{O}_3$  :  $\text{SiO}_2$ , any excess of  $\text{Al}_2\text{O}_3$  crystallising as (I). (III) is formed at  $>400^\circ$  where  $\text{Al}_2\text{O}_3$  :  $\text{SiO}_2 > 1 : 2$ ; where  $\text{Al}_2\text{O}_3$  :  $\text{SiO}_2 > 1 : 2$  (IV) is formed at  $500^\circ$ . (II) crystallises from pure  $\text{Al}_2\text{O}_3$  at  $500^\circ$ , addition of  $\text{SiO}_2$  leading to (I). The formation of dickite, nacrite, and halloysite under special conditions is discussed.

J. S. A.

**Three kaolins.** D. BELJANKIN and V. IVANOVA (Zentr. Min., 1935, A, 298—308; Chem. Zentr., 1935, ii, 3753).—Russian occurrences of normal kaolin, hydrokaolin, and halloysite are described. J. S. A.

**Bolivian minerals.** V. Franckeite. F. AHLFELD, H. HIMMEL, and W. KLEBER (Zentr. Min., 1935, A, 292—298; Chem. Zentr., 1935, ii, 3752—3753).—Crystallographic data are given. J. S. A.

**Occurrence of large zircon needles in a basic pegmatite [near Mellen, Wisconsin].** R. WILCOX (Amer. Min., 1936, **21**, 459).

L. S. T.

**Inclusions in puzzuolanas of middle Aniense valley.** A. SCHERILLO (Period. Min., 1935, **6**, 169—178; Chem. Zentr., 1935, ii, 3735).—Inclusions of limestone, lava, and a homogeneous leucitic magma of volcanic origin are described. J. S. A.

## Organic Chemistry.

**Problem of dissymmetric synthesis.** F. M. JAEGER (Chem. Weekblad, 1936, **33**, 522—533).—A lecture. S. C.

**Interpretation of the rules of fission.** O. SCHMIDT (Ber., 1936, **69**, [B], 1855—1862).—It is shown that there is strong evidence for ascribing a considerable content of kinetic energy, and hence a considerable velocity, to the loosely bound valency electrons of the double linking and, in a greater degree, to the non-coupled valency electrons of radicals; further, that the points of fission in a chain alternate with points at which fission does not occur. Exact proof is afforded that in linkings which are in the neighbourhood of the dissociation point the spin of the non-coupled valency electrons alternates and the phenomenon is propagated throughout the entire chain. The mechanism of fission is discussed.

H. W.

**Generalised prototropy.**—See this vol., 1218.

**Light reactions of halogens with organic compounds of the aliphatic series.** H. J. SCHUMACHER (Angew. Chem., 1936, **49**, 613—617).—Published work is reviewed. E. S. H.

**Mechanism of oxidation of hydrocarbons.**—See this vol., 1209, 1211.

**Hydrogen value as a means for measuring unsaturation.** W. J. C. DE KOK, H. I. WATERMAN, and H. A. VAN WESTEN (J.S.C.I., 1936, **55**, 225—228t).—Apparatus for hydrogenation using Pd or Pt on active C as catalyst is described. Pd cannot be used with aromatic compounds and with Pt hydrogenation of ethylenic linkings proceeds much faster than that of  $\text{C}_6\text{H}_6$  rings. F. R. S.

**Hydration rate of  $\beta$ -methyl- $\Delta^2$ -butene.**—See this vol., 1210.

**Reaction of free cyanogen with butadiene.** E. MÜLLER and A. FREYTAG (J. pr. Chem., 1936, [ii], **146**, 58—60).—Reaction occurs so rapidly when butadiene is passed into CNS in  $\text{Et}_2\text{O}$  that polymerisation is avoided. The  $\alpha\delta$ -dithiocyanobutene thus formed in 80% yield combines with Br in AcOH and  $\text{Cl}_2$  in  $\text{CCl}_4$  to  $\beta\gamma$ -dibromo-, m.p.  $142^\circ$ , and  $\beta\gamma$ -dichloro- $\alpha\delta$ -dithiocyanobutane. H. W.

**Photochemical polymerisation of butadiene.**—See this vol., 1215.

**Azeotropic mixture of acetylene and ethane at atmospheric pressure.** W. A. McMILLAN (J. Amer. Chem. Soc., 1936, 58, 1345).—The mixture, b.p.  $-94.5 \pm 0.1^\circ$ , contains  $40.75 \pm 0.25\%$   $C_2H_2$  and  $59.25 \pm 0.15\%$   $C_2H_6$ . H. B.

**Identification of ethyl alcohol.** M. NICLOUX (Compt. rend., 1936, 203, 16—19; cf. this vol., 535).—Duclaux's method (cf. A., 1896, ii, 504) is used to determine the composition of solutions containing  $AcOH$  (I) and  $Pr^oCO_2H$  (II), obtained by oxidising the corresponding alcohols.  $BuOH$  when oxidised affords (II) and (I) in the ratio of 3 : 1, so that knowing (II) and (I),  $[BuOH]$  and  $[EtOH]$  can be calc. Error  $\pm 5$ — $10\%$ .  $EtOH$  containing 16% of  $BuOH$  was extracted from a putrefying corpse after 55 days. J. L. D.

**Determination of ethyl alcohol.** T. E. FRIEDMANN and R. KLASS (J. Biol. Chem., 1936, 115, 47—61).—After distillation from  $Na_2WO_4$ ,  $HgSO_4$ , and  $Ca(OH)_2$ ,  $EtOH$  is oxidised with alkaline  $KMnO_4$ , the excess of which is titrated. H. G. R.

**Metallic alkoxides.**—See this vol., 1216.

**Simplified condensation with sodium ethoxides.** ( $\beta\zeta$ -Dimethyl- $\Delta^4$ -heptenol.) G. FESTER and D. PUCCI (Ber., 1936, 69, [B], 2017—2018).—The prep. of  $NaOEt$  in suitable form by gradual addition of abs.  $EtOH$  to  $Na$  under ligroin, b.p.  $100$ — $120^\circ$ , is described. Methylheptenone,  $CH_2Cl \cdot CO_2Et$ , and  $NaOEt$  afford  $Et \alpha\beta$ -oxido- $\beta\zeta$ -dimethyl- $\Delta^4$ -octenoate, whence dimethylheptenol and  $\beta\zeta$ -dimethyl- $\Delta^4$ -heptenol (I). (I) when esterified with  $AcCO_2H$  and then treated with  $NH_2 \cdot CO \cdot NH \cdot NH_2$  gives the *semicarbazone*,  $C_{13}H_{23}O_3N_3$ , m.p.  $100^\circ$ . (I) is not identical with yacarol (A., 1934, 509). H. W.

**Organic electrolyses.**—See this vol., 1214.

**Esterification of glycerol with chloroacetic acid and trichloroacetic acid.** J. HELGESON and E. H. SHAW, jun. (Proc. S. Dakota Acad. Sci., 1935, 14, 22—26).—The process is a series of bimol. reactions. CH. ABS. (r)

**Sugar alcohols. V. Chemical constitution and sweet taste.** C. J. CARR, F. F. BECK, and J. C. KRANTZ, jun. (J. Amer. Chem. Soc., 1936, 58, 1394—1395).—The anhydrides of various alcohols (e.g., glycerol, arabitol, mannitol, sorbitol, dulcitol) are generally devoid of sweet taste. There is no significant relationship between sweetness and the no. of C atoms or OH groups in the alcohols. H. B.

**Synthesis of *dl*-arabitol.** R. LESPIEAU (Compt. rend., 1936, 203, 145—146).— $\alpha$ -Chloro- $\Delta^4$ -pentinene- $\gamma\delta$ -triol (A., 1928, 989) affords a  $Ac_3$  derivative, b.p.  $149.5$ — $150.5/9$  mm., reduced ( $H_2$ -Pd) to  $\gamma\delta$ -triacetoxy- $\Delta^4$ -pentene, b.p.  $148$ — $149/14$  mm., which with  $AgClO_4 \cdot OsO_4$  affords pentitol  $\alpha\beta\gamma$ -triacetate, converted into *dl*-arabitol penta-acetate, m.p.  $96$ — $96.5^\circ$  (cf. A., 1934, 891). J. L. D.

**Thermal decomposition of ethylene oxide.**—See this vol., 1208.

**Decomposition of alkyl nitrites.**—See this vol., 1208.

**Molybdenum chlorohydrin and normal glycol molybdate.**—See this vol., 1218.

**Xylitol penta-acetate.** G. BERTRAND (Compt. rend., 1936, 203, 143—144; cf. A., 1892, i, 28).—The acetate (prep. described), m.p.  $60^\circ$ , is optically inactive. J. L. D.

**Organic sulphur compounds. IV. Molecular compounds of sulphides with mercuric chloride.** L. BERMEO and J. J. HERRERA (Anal. Fis. Quím., 1934, 32, 682—689).— $R_2S$  with  $HgCl_2$  in  $EtOH$  gives a ppt. of the mol. compound. The following compounds were prepared:  $(CH_2Ph)_2S \cdot HgCl_2$ , m.p.  $136^\circ$ ,  $(CH_2 \cdot CH_2Ph)_2S \cdot 2HgCl_2$ , m.p.  $101^\circ$ ,  $(CH_2 \cdot CH_2 \cdot CH_2Ph)_2S \cdot 2HgCl_2$ , m.p.  $120^\circ$ ,  $(CHMePh)_2S \cdot HgCl_2$ , m.p.  $110$ — $112^\circ$ . F. R. G.

**Preparation of alkanesulphonyl chlorides.** T. B. JOHNSON and J. M. SPRAGUE (J. Amer. Chem. Soc., 1936, 58, 1348—1352).—Partly a more detailed account of work previously reviewed (this vol., 974). Good yields of  $AlkSO_2Cl$  are obtained when  $SAlk \cdot C(NH) \cdot NH_2 \cdot HX$  [ $X = Cl$  (I),  $NO_2$ ,  $OAc$ ,  $SO_3$ ] are treated with  $Cl_2$  in  $H_2O$  at  $<15^\circ$ ; when  $X$  is  $Br$  the product is contaminated with  $AlkSO_2Br$  (which can be similarly prepared using  $Br$ ). (I) can be conveniently prepared from  $AlkOH$ ,  $CS(NH_2)_2$ , and  $HCl$ ; isolation is not necessary. The following are new: *S*-isopropylisothiocabamide hydrobromide, m.p.  $76$ — $78^\circ$ ; *S*-*n*-heptylisothiocabamide hydrobromide, m.p.  $92$ — $94^\circ$ , and acetate, m.p.  $136$ — $137^\circ$ ;  $\beta$ -phenylethylisothiocabamide hydrochloride, m.p.  $113$ — $114^\circ$ ; *SS*-ethylene-diisothiocabamide hydrochloride, m.p.  $247$ — $248^\circ$ , and acetate, m.p.  $157$ — $158^\circ$ ; *n*-heptane-, b.p.  $124$ — $126/9$  mm., and  $\beta$ -phenylethane-, b.p.  $121$ — $123/3$  mm., m.p.  $32$ — $33^\circ$ , -sulphonyl chlorides; *n*-heptane-, m.p.  $74$ — $75^\circ$ , and  $\beta$ -phenylethane-, m.p.  $121.5$ — $122.5^\circ$ , -sulphonamides. H. B.

**Determination of mol. wts. of fatty acids in benzene.**—See this vol., 1197.

**Reaction of esters with ammonia.** H. E. FRENCH, O. H. JOHNSON, and E. RATEKIN (J. Amer. Chem. Soc., 1936, 58, 1346—1347).— $NH_3 \cdot Ac$  (69.7, 68.8, 18.6, and 2.9%) and  $NH_3 \cdot OAc$  (6.1, 7.7, 4.8, and 2.1%) are formed from *n*-, *iso*-, *sec*-, and *tert*- $BuOAc$ , respectively, with aq.  $EtOH \cdot NH_3$  (40 wt.-%  $EtOH$  in  $H_2O$  saturated with  $NH_3$  at  $25$ — $30^\circ$ ) at  $25^\circ$  after 120, 120, 120, and 360 hr., respectively. No reaction occurs with gaseous  $NH_3$  at  $100^\circ$  under pressures up to 8 atm. H. B.

**Interaction of sodium formate and sodium hydroxide.**—See this vol., 1209.

**Chloroformates.** A. PERRET and J. BIECHLER (Compt. rend., 1936, 203, 84—87).— $ClCO_2CH_2Cl$ ,  $ClCO_2CHCl_2$ ,  $ClCO_2CCl_3$ , and  $CO(CCl_3)_2$  react with  $NaI$  and  $NaBr$  in  $COMe_2$  liberating halogen. The reactivity of the first three substances increases with the no. of substituted  $Cl$  atoms. C. R. H.

**Decomposition of the  $\gamma$ -bromobutyrate ion.**—See this vol., 1210.

**Fatty acids and their esters. I. Cryoscopy and ebullioscopy of fatty acids.** H. N. BROCKLESBY. II. Mol. wts. of polymerised esters. H. N. BROCKLESBY. III. Iodine values by the bromine vapour method. H. N. BROCKLESBY and K. F. HARDING (Canad. J. Res., 1936, 14, B, 222—230,

231—236, 237—242).—I. Ebullioscopically, and cryoscopically in  $C_6H_6$ , saturated fatty acids show decreasing degree of association up to lauric acid; above this, degree of association remains substantially const. Unsaturation decreases the tendency of fat acids of the same C content to associate.

II. Allowing for effect of solute on dissociation of the solvent, raw linsced oil gives normal mol. wts. by b.-p. and f.-p. methods. Polymerised oils and esters behave similarly and hence cannot be assumed to be associated.

III. A modified Br-vapour method, which allows the determination of substitution, is described. The unsaturation of conjugated and non-conjugated materials can be determined satisfactorily, but owing to substitution that of oxidised or polymerised esters cannot.

F. C. B. M.

**Chloro-iodo-derivatives of linoleic and linolenic acids and dichlorodi-iodo-derivative of linolenic acid.** Y. TOYAMA and T. TSUCHIYA (J. Soc. Chem. Ind. Japan, 1936, 39, 219—220b).—Linoleic acid (1 mol.) and ICl (1 mol.) in AcOH give  $\lambda$ -(chloroiodo)- $\Delta^6$ -octadecenoic acid, converted by  $O_3$  into azelaic and nonenoic acids. Linolenic acid (1 mol.) and ICl (1 mol.) yield  $\nu$ -(chloroiodo)- $\Delta^{6,8}$ -octadecadienoic acid, which with  $O_3$  gives MeCHO,  $CO_2$ , azelaic and hexenoic acids. With 2 mols. of ICl,  $\lambda,\nu$ -(dichlorodi-iodo)- $\Delta^6$ -octadecadienoic acid is obtained.

E. W. W.

**Occurrence of new highly unsaturated fatty acids,  $C_{26}H_{40}O_2$  and  $C_{26}H_{42}O_2$ , in tunny oil.** S. UENO and C. YONESE (Bull. Chem. Soc. Japan, 1936, 11, 437—442).—The fatty acids from the oil of tunny fish, fractionated as Me esters at 4 mm., and then through their Na salts (in  $COMe_2$ ), yield, in addition to sciodonic, nisinic, and clupanodonic acids, an acid which is hydrogenated to cerotic acid; from neutralisation and I vals., and from analysis of its polybromide, it is regarded as a mixture of *thynnac acid*,  $C_{26}H_{40}O_2$  (with six double linkings), and *shibic acid*,  $C_{26}H_{42}O_2$  (five double linkings).

E. W. W.

**Synthesis of  $\alpha$ -hydroxy- and  $\alpha$ -amino-decoic acid from the oxidation product of oleic acid.** Y. KOBATA (J. Agric. Chem. Soc. Japan, 1935, 11, 709—714).—Nonaldehyde (I) (by ozonolysis of oleic acid) is converted, through its  $NaHSO_3$  compound, into the *cyanohydrin*, m.p. 149—149.5°, which is hydrolysed to  $\alpha$ -hydroxydecoic acid (II), m.p. 69.5—70°. (I), with  $NH_3$ -MeOH followed by HCN and then HCl, yields  $\alpha$ -aminodecoic acid, m.p. 219—221°, yielding (II) with  $HNO_2$ .

CH. ABS. (r)

**Sulphonated oils. XXVII. Preparation and properties of pure salts of the sulphuric ester of  $\alpha$ -hydroxystearic acid.** K. NISHIZAWA (J. Soc. Chem. Ind. Japan, 1936, 39, 234b).— $\alpha$ -Hydroxystearic acid (I), isolated from the regenerated fatty acid from the interaction of olive oil and conc.  $H_2SO_4$ , was converted into its sulphuric ester (II) by the action of  $ClSO_3H$  in  $Et_2O$  at  $0 \pm 1^\circ$ . The K H salt of (II) was used to prepare the  $K_2$ ,  $Na_2$ ,  $(NH_4)_2$ , Na H, and  $NH_4$  H salts. Measurements were made at 25° of the relative viscosities and relative surface tensions against air and against kerosene of the aq. solutions of these six salts. The results indicate the

identity of (I) with the hydroxystearic acid isolated from "Plastabitol V."

F. R.

**Mechanism of thermal poly-condensation reactions.**—See this vol., 1209.

**$\beta\gamma$ -Dihydroxypropylmalonic ester and its propyl homologue.** R. M. LEEKLEY and E. M. SHAW, jun. (Proc. S. Dakota Acad. Sci., 1935, 14, 27—28).—Et ( $\beta\gamma$ -dihydroxypropyl)-(*di*-p-nitrobenzoate, m.p. 170—171°) and propyl-( $\beta\gamma$ -dihydroxypropyl)-(*di*-p-nitrobenzoate, m.p. 166—168°) -malonate are described.

CH. ABS. (r)

**Unsaturated acids from hydroxymethylene compounds.** W. BORSCHÉ and J. NIEMANN (Ber., 1936, 69, [B], 1993—1998).—Condensation of Et hydroxymethylenepropionate with  $CH_2(CO_2H)_2$  (I) in  $C_6H_5N$  at 100° gives *trans*- $\alpha$ -methylglutaconic acid, m.p. 144°, whilst Et  $\gamma$ -cyano- $\alpha$ -methylbutenoate, b.p. 133—137°/15 mm., is obtained with  $CN \cdot CH_3 \cdot CO_2H$  (II). Similarly Et hydroxymethylenephylacetate (III) affords  $\alpha$ -phenylglutaconic acid, m.p. 166—167° ( $Me_2$  ester, b.p. 180—182°/15 mm.), hydrogenated (Pd) to  $Me_2$   $\alpha$ -phenylglutarate, b.p. 178—179°/13 mm., which is hydrolysed and then converted by distillation into  $\alpha$ -phenylglutaric anhydride, m.p. 93°, which when distilled gives  $CO_2$ , phenylsacrotonic acid (IV), and some  $\alpha$ - $C_{10}H_7 \cdot OH$ . (III) and (II) yield Et  $\gamma$ -cyano- $\alpha$ -phenyl- $\Delta^2$ -butenoate, b.p. 183—187°/19 mm., transformed by  $NaOH$ - $MeOH$ - $H_2O$  into phenylisocrotononitrile, m.p. 61—62°, and some (IV). Et  $\gamma$ -cyano- $\alpha$ -phenylbutyrate has m.p. 132°. Hydroxymethylene-camphor and (I) give an acid (V),  $C_{13}H_{18}O_3$ , m.p. 104—106° ( $Me$  ester, b.p. 180—181°/18 mm.), (?)  $\beta$ -3-camphorylidenepropionic acid,

constitution is sug-

gested by the ready ozonolysis of it and the corresponding ketone to camphorquinone, but its ready decarboxylation to 3-ethylidenecamphor, b.p. 224—226°/764 mm., and its conversion by conc.  $H_2SO_4$  or  $SOCl_2$  into the lactone,  $C_{13}H_{16}O_2$ , m.p. 62—63°, suggest the alternative structure

stance of allyl tautomerism is presented. The liquid portions remaining in the prep. of (V) give a substance,  $C_{13}H_{17}O_2Cl$ , b.p. 117—119°/13 mm., when treated with  $SOCl_2$ . Camphorylidenepropionitrile has b.p. 188—192°/16 mm., m.p. 72°. Formylfluorene [2:4-dinitrophenylhydrazones, m.p. 208° (decomp.)] and (I) yield  $\beta$ -9-fluorenylidenepropionic acid, m.p. 202—203°. Attempts to use the  $OH \cdot CH$  derivatives of  $CH_2Ph \cdot CO_2Et$ ,  $CH_2Ph \cdot CN$ , or camphor with  $\beta$ - $C_{10}H_7 \cdot NH_2$  in the synthesis of cinchoninic acids gave only 2-methyl-5:6-benzocinchoninic acid obtained without their participation; the *enamines*  $CN \cdot CPh \cdot CH \cdot NH \cdot C_{10}H_7$ , m.p. 190—191°, and  $C_{10}H_{14}O \cdot CH \cdot NH \cdot C_{10}H_7$ , m.p. 186—187°, are obtained incidentally.

H. W.

**Decapentaene- $\alpha\kappa$ -dicarboxylic acid.** R. KUHN and C. GRUNDMANN (Ber., 1936, 69, [B], 1979—1981).—Addition of  $Et_2C_2O_4$  and Et  $\Delta^{5,7}$ -decatetraenoate to  $RbOEt$  in  $Et_2O$  gives  $Et_2$  oxalodecatetraenoate, m.p. 147° ( $Rb$  derivative), the Ac derivative of which is

reduced by Al-Hg in Et<sub>2</sub>O to the corresponding H<sub>2</sub>-compound, converted by cold KOH-MeOH into Me<sub>2</sub>Δ<sup>27,28</sup>-*decapentaene-α,κ-dicarboxylate* CO<sub>2</sub>Me[CH:CH]<sub>5</sub>·CO<sub>2</sub>Me, m.p. 223° (Berl), which with conc. H<sub>2</sub>SO<sub>4</sub> slowly gives the characteristic carotenoid colour reaction. *Decapentaene-α,κ-dicarboxylic acid* has m.p. 229—230° (decomp.) when rapidly heated above 220°. Rb cannot be replaced by K in the condensation.

H. W.

**Preparation of diethoxysuccinic esters.** M. MEYER (Compt. rend., 1936, 203, 189—192; cf. A., 1933, 491).—Et<sub>2</sub> sodioethoxymalonate (I) with Et<sub>2</sub> bromoethoxymalonate, b.p. 132°/15 mm. [prepared from (I) and Br], in boiling PhMe affords Et<sub>4</sub> α,β-diethoxyethanetetra-carboxylate, b.p. 154°/1 mm., hydrolysed to the acid, which loses 2 CO<sub>2</sub> to give a mixture of stereoisomeric diethoxysuccinic acids. The mixed Bu esters, b.p. 140—141°/3.5 mm., with N<sub>2</sub>H<sub>4</sub> afford the *dl*- and *meso*-hydrazides, m.p. 194° and 242°, identical with those derived from *dl*- and *meso*-tartaric acid, respectively.

J. L. D.

**Oxidation of the methyl group in the animal body.** R. KUHN, F. KÖHLER, and L. KÖHLER (Z. physiol. Chem., 1936, 242, 171—197; cf. A., 1933, 1325; Hildebrandt, A., 1901, ii, 180).—After administration of β<sub>2</sub>-dimethylheptadiene (I), geranic acid (II), geraniol (III), and citral (IV) to rabbits their urine contains α,ζ-dimethylhexadiene-α,ζ-dicarboxylic acid (V), m.p. 193—194°, which, with PtO<sub>2</sub>-H<sub>2</sub> yields α<sub>2</sub>-dimethylsuberic acid (VI), b.p. 165—167°/0.4 mm. (*bis*-*p*-bromophenacyl ester, m.p. 110.5—111.5°). (II), (III), and (IV) also yield thus d-α<sub>2</sub>-dimethylhexadine-α,ζ-dicarboxylic acid, m.p. 102.6—103.6° (corr.), [α]<sub>D</sub><sup>25</sup> +15.25° in 2*N*-NaOH, which, treated in AcOH with O<sub>3</sub> and then Pt-H<sub>2</sub>, yields AcCO<sub>2</sub>H. Similarly Me β-methyl-β-hexylacrylate (VII) is converted in the body into β-methylazelaic acid (VIII), b.p. 173—175°/0.002 mm. (*bis*-*p*-bromophenacyl ester, m.p. 93—96°), and Me β-methyl-β-nonylacrylate (IX) into β-methylbutene-α,γ-dicarboxylic acid (X), b.p. 145—150°/0.001 mm. (*bis*-*p*-bromophenacyl ester, m.p. 95—97°). For the synthesis of (VI) *dl*-3-methylcyclohexanone is treated with EtOAc and Na giving *dl*-6-acetyl-3-methylcyclohexanone, which with alkali gives *dl*-ζ-acetyl-β-methylhexoic acid, b.p. 150°/8 mm., and this with PtO<sub>2</sub>-H<sub>2</sub> in AcOH gives *dl*-ζ-hydroxy-β-methylcyclooctoic acid, b.p. 155.5°/6 mm., which, with HBr, in AcOH, gives the corresponding bromo-acid, b.p. 143—144°/6 mm., the Me ester of which in PhMe with KCN followed by hydrolysis with KOH gives (VI). (V) in Et<sub>2</sub>O with a trace of I, irradiated with ultra-violet light, undergoes *cis*-*trans*-rearrangement, yielding a form of m.p. 123.8—124.2°. (V) in EtOAc treated with O<sub>3</sub> and then with Pt-H<sub>2</sub> gives AcCO<sub>2</sub>H, lävulaldehyde, and CHO·CO<sub>2</sub>H. Me hexyl ketone in C<sub>6</sub>H<sub>6</sub> with CH<sub>2</sub>Br·CO<sub>2</sub>Me and Zn gives the Me ester, b.p. 123.5°/20 mm., of an acid from which H<sub>2</sub>O is eliminated by ZnCl<sub>2</sub> and Ac<sub>2</sub>O at 155—160° to give (VII), b.p. 100—102°/18 mm. Similarly Me nonyl ketone gives (IX), b.p. 108—109°/3 mm., Et ζ-acetylhexoate, b.p. 83—84°/0.4 mm., with CH<sub>2</sub>Br·CO<sub>2</sub>Et gives an Et<sub>2</sub> ester, b.p. 130—132°/0.5 mm., which yields (VIII), Et lävulate gives first Et<sub>2</sub> β-hydroxy-β-

4 L

methyladipate, b.p. 92.5°/0.01 mm., and then (X), and Et δ-acetylvalerate gives β-methylhexene-α<sub>2</sub>-dicarboxylic acid (XI), m.p. 100—101° (corr.), b.p. 145—147°/0.005 mm. (*bis*-*p*-bromophenacyl ester, m.p. 102—103°). (XI) is not found in the urine of rabbits given (IX). Et cyclopentanone-2-carboxylate in PhMe with Na and AcCl gives Et 2-acetylcyclopentanone-2-carboxylate, b.p. 103.5—105°/3.3 mm. β-Bromo- and β-iodo-heptadecane with CHNa(CO<sub>2</sub>Et)<sub>2</sub> give the Et<sub>2</sub> ester, b.p. 180—182°/0.3 mm., of β-heptadecylmalonic acid, m.p. 86.5—87°, which at 180—200° gives β-methylstearic acid, m.p. 48.5—49° [Me ester (XII), b.p. 148—149°/0.4 mm.]. The urine of rabbits given (XII) yields an oil possibly containing a dicarboxylic acid. The biological oxidation of Me is a general reaction not confined to ω-Me and probably takes place always in the stages ·CH<sub>2</sub>· → ·CH<sub>2</sub>·OH → ·CHO → ·CO<sub>2</sub>H. The ease and extent of the oxidation vary with the nature of the substance, the animal concerned, and the method of administration.

W. McC.

**Colour reaction for organic acids and detection of small quantities of citric acid.** R. CASARES (Anal. Fis. Quim., 1936, 34, 594—596).—Agaric acid gives a characteristic violet-brown colour, *d*-, *l*-, and *meso*-tartaric acid, but not esters, give the green colour, in the Ac<sub>2</sub>O-C<sub>6</sub>H<sub>5</sub>N colour reaction for org. acids (cf. Fürth and Herrmann, A., 1935, 1516). Pyridine tartrate, m.p. 124°, gives a red colour with Ac<sub>2</sub>O. 0.015 mg. of citric acid may be detected by the reaction.

L. A. O'N.

**Production of citric acid.** F. KNOOP and C. MARTIUS (Z. physiol. Chem., 1936, 242, 1).—AcCO<sub>2</sub>H mixed with oxalacetic acid in aq. Na<sub>2</sub>CO<sub>3</sub> and then oxidised with H<sub>2</sub>O<sub>2</sub> gives in 20—30 hr. a 35% yield of Ca citrate. This synthesis probably occurs in the animal organism and possibly the reverse process also.

W. McC.

**Decomposition of ascorbic acid in acid and alkaline solution.** A. CARTENI and A. MORELLI (Boll. Soc. ital. Biol. sperim., 1936, 11, 158—160).—The stability at 37° decreases rapidly with increasing *p*<sub>H</sub> from 4.93 to 9.64.

F. O. H.

**Derivatives of glycuronic acid. VII. Synthesis of aldobionic acids.** R. D. HOTCHKISS and W. F. GOEBEL (J. Biol. Chem., 1936, 115, 285—292; cf. A., 1935, 1483).—Diisopropylidenegalactose, Me 1-α-bromo-2 : 3 : 4-triacetylglycuronate (I), and Ag<sub>2</sub>O in dry Et<sub>2</sub>O give the Me ester, m.p. 112.5—114°, [α]<sub>D</sub><sup>25</sup> -6.8° in CHCl<sub>3</sub>, of 1 : 2 : 3 : 4-diisopropylidenegalactose-6-β-2' : 3' : 4'-triacetylglycuronide, which, when hydrolysed first by Ba(OH)<sub>2</sub> and then by 0.02*N*-H<sub>2</sub>SO<sub>4</sub>, gives galactose-6-β-glycuronide, identical with that obtained from gum acacia (cf. Challinor *et al.*, A., 1931, 465). This confirms the structure of (I). (I) and β-glucose 1 : 2 : 3 : 4-tetraacetate give similarly Me β-gentiobionate heptaacetate, m.p. 198—199°, [α]<sub>D</sub><sup>25</sup> -11° in CHCl<sub>3</sub>, converted by Ac<sub>2</sub>O-ZnCl<sub>2</sub> into the α-compound, m.p. 201—202°, [α]<sub>D</sub><sup>25</sup> +48.4°.

R. S. C.

**tert.-Butylthiolacetic acid and related compounds.** N. HELLSTROM and T. LAURITZSON (Ber., 1936, 69, [B], 2003—2006).—Bu<sup>t</sup>Br evolves gas and

consumes alkali when heated with  $\text{SNa}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NHPh}$  or  $\text{SNa}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\text{Me-}p$  and does not appear to react with  $\text{SNa}\cdot\text{CH}_2\cdot\text{CO}_2\text{Na}$  in  $\text{H}_2\text{O}$  or  $\text{EtOH-H}_2\text{O}$ .  $\text{Bu}^n\text{OH}$  and  $\text{SH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  in  $2N\cdot\text{HCl}$  at  $100^\circ$  give *tert*-butylthiolacetic acid (I), b.p.  $107\text{--}109/2$  mm. (compound  $\text{SBu}^n\cdot\text{CH}_2\cdot\text{CO}_2\text{HgCl}_2$ , m.p.  $86\text{--}89^\circ$  and decomp.  $175\text{--}177^\circ$  after re-solidification); under these conditions  $\text{Pr}^n\text{OH}$ ,  $\text{Pr}^i\text{OH}$ ,  $\text{Bu}^n\text{OH}$ , and  $\text{Bu}^i\text{OH}$  do not react. (I) is transformed by  $\text{SOCl}_2$  into the corresponding chloride, b.p.  $68\text{--}70/6$  mm., converted by  $\text{NH}_2\text{Ph}$  in  $\text{C}_6\text{H}_6$  into *tert*-butylthiolacetanilide, m.p.  $80\text{--}81^\circ$  (corresponding sulphoxide, m.p.  $146\cdot5\text{--}147\cdot5^\circ$ ), and by  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$  into *tert*-butylthiolacet-*p*-toluidide, m.p.  $87\text{--}88^\circ$ . Cautious oxidation of (I) with  $\text{H}_2\text{O}_2$  in  $\text{COMe}_2$  at  $3\text{--}4^\circ$  gives the corresponding sulphoxide, m.p.  $110\text{--}111^\circ$ . Treatment of  $\text{SBu}^n\cdot\text{CH}_2\cdot\text{CO}_2\text{Na}$  with  $\text{H}_2\text{O}_2$  yields  $\text{Bu}^n\text{SH}$ , b.p.  $64\text{--}65^\circ$ , in 60% yield. H. W.

**Fission of disulphides by alkali. III. Fission of dithiodiacetic acid with alkali.** A. SCHÖBERL (Ber., 1936, 69, [B], 1955; cf. A., 1933, 1276).—A claim for priority against Kharasch *et al.* (this vol., 631) and Shinohara *et al.* (A., 1934, 761). H. W.

**Keratin. Hydrolysis of disulphide compounds.** A. SCHÖBERL (Collegium, 1936, 412—421).—Disulphides,  $(\text{-SR})_2$ , are hydrolysed by  $\text{NaOH}$  to  $\text{RSH}$  and  $\text{RS}\cdot\text{OH}$ , which may then form  $\text{RSH}$  and  $\text{RSO}_2\text{H}$  or  $\text{RSO}_3\text{H}$ , respectively.  $(\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{S})_2$  is converted into  $\text{OH}\cdot\text{S}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  first and subsequently into  $\text{H}_2\text{S}$  and  $\text{CHO}\cdot\text{CO}_2\text{H}$ . Na salts of the disulphides are hydrolysed by boiling in neutral solution. Cystine is decomposed by boiling with  $\text{NaOH}$  into cysteine,  $\text{H}_2\text{S}$ , and  $\text{NH}_3$  but there must be the intermediate formation of  $\text{R}\cdot\text{SO}_2\text{H}$ -type acids followed by that of  $\text{CHO}\cdot\text{CO}_2\text{H}$  type. Cystine is rendered more sensitive to  $\text{NaOH}$  by substituting the  $\text{NH}_2$  groups. Wool is a typical disulphide compound sensitive to boiling  $\text{H}_2\text{O}$  or  $\text{NaOH}$ . D. W.

**Selenodicarboxylic acids and diselenodicarboxylic acids.** A. FREDGA (Uppsala Univ. Arsskr., 1935, No. 5, 232 pp.).—Se is determined in org. compounds by digestion with  $\text{H}_2\text{SO}_4\text{--HNO}_3$ , followed by pptn. of the Se (weighed as such) with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$ . *dl-αα'*-Selenodipropionic acid (I), m.p.  $147\text{--}148^\circ$  (from  $\text{K}_2\text{Se}$  and  $\text{CHMeBr}\cdot\text{CO}_2\text{H}$ ), is resolved by means of its *brucine* salt; the *d*-(II) and *l*-acids have m.p.  $123\cdot5\text{--}124\cdot5^\circ$ ,  $[\alpha]_D^{25} \pm 234^\circ$ ; the *meso*-acid, isolated from the mother-liquors from (I), has m.p.  $128\text{--}129^\circ$  (*quinine* salt). *dl-ββ'*-Selenodipropionic acid, m.p.  $147\cdot5\text{--}148^\circ$  (*Ag* and *Pb* salts), is prepared similarly. *dl-αα'*-Selenodibutyric acid, m.p.  $100\text{--}101^\circ$ , is resolved by means of the *brucine* salt; the *d*-acid has m.p.  $76\text{--}77^\circ$ ,  $[\alpha]_D^{25} + 201\cdot9^\circ$ ; the *meso*-acid has m.p.  $84\text{--}85^\circ$  (*brucine* salt). Hydrolysis of the product from  $\text{K}_2\text{Se}$  and  $\text{CMe}_3\text{Br}\cdot\text{CO}_2\text{Et}$  yields *αβ'*-selenodisobutyric acid, m.p.  $154\text{--}155^\circ$ . *meso-αα'*-Selenobisphenylacetic acid has m.p.  $178\text{--}179^\circ$  (*quinine*, *strychnine*, and *Ag* salts); the *dl*-acid, m.p.  $153\cdot5\text{--}154\cdot5^\circ$ , is resolved, through the *strychnine* and *quinine* salts, into the *d*- and *l*-acids, m.p.  $144\text{--}145^\circ$ ,  $[\alpha]_D^{25} \pm 534^\circ$ . Oxidation of (II) yields *l-αα'*-seleninylidipropionic acid,  $[M]_D^{25} - 34\cdot5^\circ$ . The following are prepared similarly: *d-αα'*-seleninylidibutyric acid,  $[M]_D^{25} + 173\cdot5^\circ$ ; *l-αα'*-seleninylbisphenylacetic acid,

$[M]_D^{25} - 2262^\circ$ ; *l-tetrahydroselenophenoxide-αα'*-dicarboxylic acid,  $[M]_D^{25} - 535\cdot5^\circ$ . The following are prepared by direct halogenation: (*dibromoseleno*)-diacetic, *-di-α-propionic*, and *-di-β-propionic acids*; (*di-iodoseleno*)-diacetic, m.p.  $124^\circ$ . and *-αβ'*-diisobutyric, m.p.  $137^\circ$ , acids.  $\text{Se}(\text{CH}_2\cdot\text{CO}_2\text{H})_2$  and  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$  afford the compound,

$\text{CO} < \begin{smallmatrix} \text{CH}_2 \\ \text{O} \end{smallmatrix} > \text{Se}(\text{CH}_2\cdot\text{CO}_2\text{H})_2$ , m.p.  $177^\circ$  (*Pb* and *Ag* salts). *dl-αα'*-Diselenodipropionic acid, m.p.  $85\text{--}88^\circ$ , is resolved, though the *brucine* salt, into the *d*- and *l*-acids, m.p.  $86\cdot5\text{--}87\cdot5^\circ$ ,  $[\alpha]_D^{25} \pm 254^\circ$ ; the *meso*-acid has m.p.  $108\cdot5\text{--}109\cdot5^\circ$ . *meso-αα'*-Diselenodipropionic acid has m.p.  $71\text{--}73^\circ$  (*strychnine* salt), and *ββ'*-diselenodipropionic acid, m.p.  $137^\circ$ . *dl-αα'*-Diselenodibutyric acid is resolved, by means of the *quinidine* and *morphine* salts, into the *d*- and *l*-acids, m.p.  $50\text{--}52^\circ$ ,  $[\alpha]_D^{25} \pm 293^\circ$ . *d-αα'*-Diselenobisphenylacetic acid, m.p.  $160\text{--}165^\circ$ ,  $[\alpha]_D^{25} + 446\cdot1^\circ$ , is obtained from the *dl*-acid by means of the *strychnine* salt. *meso*- and *dl*- (III) *-αα'*-Diselenocyanate-adipic acids are prepared from the corresponding *αα'*-dibromoadipic acids and  $\text{KCNSe}$ . (III) is cyclised (*K* salt and  $\text{H}_2\text{SO}_4$ ) to *meso*-cyclotetramethylenediseleno-*αα'*-dicarboxylic acid, m.p.  $172\text{--}176^\circ$ . The appropriate diseleno-acid and  $\text{N}_2\text{O}_4$  afford *d-α-seleninophenylacetic acid*, m.p.  $93^\circ$ ,  $[M]_D^{25} + 1020^\circ$ , and *l-αα'*-diseleninoadipic acid,  $[M]_D^{25} - 63\cdot5^\circ$ . Shaking the appropriate diselenodicarboxylic acid with  $\text{Hg}$  affords *mercuribis-(α-selenopropionic)* (*d*- and *l*-forms,  $[\alpha]_D^{25} + 2\cdot8^\circ$  and  $-2\cdot4^\circ$ ), *-(α-selenobutyric)*, and *-(α-selenoisobutyric)* acid. Solubilities and dissociation consts. are given for most of the acids described. CH. ABS. (r)

**Kinetics of the reactions of polymeric aldehydes. I. Rate of dissolution of paraformaldehyde.** J. LÖBERING (Ber., 1936, 69, [B], 1844—1854).—Measurements of the rate of dissolution of paraformaldehyde show that the formula for a unimol. change is applicable. The influence of  $[\text{H}^+]$  and  $[\text{OH}^-]$  is similar to that observed by Hess in the depolymerisation of  $(\text{CH}_2\text{O})_n$  in  $\text{H}_2\text{O}$ . The temp. coeff. increases with rising temp. The rate of dissolution is therefore governed by that of depolymerisation. H. W.

**Aldolase. I. Aldol condensation of dihydroxyacetonephosphoric acid with acetaldehyde. II. Aldol condensation of dihydroxyacetone with glyceraldehyde.** O. MEYERHOF, K. LOHMANN, and P. SCHUSTER (Biochem. Z., 1936, 286, 301—318; 319—335).—I. In dialysed or inactivated yeast or muscle extract an aldolase is present which condenses dihydroxyacetonephosphoric acid (I), arising from hexose diphosphate, with  $\text{MeCHO}$  with the formation of a methyltetrose phosphate (II),  $[\alpha]_D^{25} + 1\cdot8^\circ$  (cryst. *Ag* salt,  $\text{C}_5\text{H}_9\text{O}_6\text{P}\cdot\text{Ag}_2\cdot\text{H}_2\text{O}$ ;  $[\alpha]_D^{25}$  for  $\text{Na}_2$  salt  $+14\cdot7^\circ$ ,  $\text{Na H}$  salt  $+5\cdot1^\circ$ ). The same product can be obtained using undialysed maceration extract in presence of  $\text{NaF}$ , glucose, and  $\text{MeCHO}$ . The reaction of formation of (II) is reversible and obeys the mass law. (II) is hydrolysed by alkali, gives but little  $\text{AcCHO}$  on acid hydrolysis, gives with acid  $\text{KMnO}_4$  phosphoglycollic acid (III),  $\text{MeCHO}$ , and  $\text{CO}_2$ , with  $\text{H}_2\text{O}_2$  in alkaline solution (III) and  $\text{HCO}_2\text{H}$ , and with phosphatase is hydrolysed to the free methyl-

tetrose (osazone, m.p. 165—167°). (II) is therefore  $\text{Me}[\text{CH}(\text{OH})]_2 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{O} \cdot \text{PO}_3\text{H}_2$ .

II. Under similar conditions, *d*-glyceraldehyde with (I) gives *d*-fructose-1-phosphoric acid (IV), free acid  $[\alpha]_D -52.5^\circ$ , whilst *r*-glyceraldehyde gives an equimol. mixture (V) of (IV) and *l*-sorbitol-1-phosphate, isolated as Ba and brucine mixed salts but not separated completely. The rotation, hydrolysis curve, and production of glucosazone after dephosphorylation of (IV) identified it with the ester obtained by Tanko and Robison (A., 1935, 660) from hexose diphosphate by partial dephosphorylation with bone phosphatase. The free sugars from (IV) and (V) were 90 and 45% fermentable, respectively, the latter corresponding with the non-fermentability of *l*-sorbitol.

P. W. C.

**Transformation of carboxylic acids into aldehydes.** C. GRUNDMANN [with F. BAR and H. TRISCHMANN] (Annalen, 1936, 524, 31—48).—The synthesis follows the lines,  $\text{R} \cdot \text{COCl} \rightarrow \text{R} \cdot \text{CO} \cdot \text{CHN}_2 \rightarrow \text{R} \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{O} \cdot \text{OAc} \rightarrow \text{OH} \cdot \text{CHR} \cdot \text{CH}_2 \cdot \text{OH} \rightarrow \text{R} \cdot \text{CHO} + \text{CH}_2\text{O}$ . It is not successful for the prep. of  $\alpha$ -unsaturated aldehydes. Thus stearyl chloride is converted by  $\text{CH}_3\text{N}_2$  into  $\alpha$ -diazononadecan- $\beta$ -one, m.p. 69°, transformed by AcOH at 70° into  $\beta$ -ketononadecyl acetate, m.p. 72° (Berl); this is reduced by  $\text{Al}(\text{OPr}^i)_3$  in  $\text{Pr}^i\text{OH}$  to nonadecane- $\alpha$ - $\beta$ -diol, m.p. 85°, oxidised by  $\text{Pb}(\text{OAc})_4$  in  $\text{AcOH} \cdot \text{C}_6\text{H}_6$  to stearaldehyde, m.p. 63°. Oleyl chloride similarly gives  $\beta$ -keto- $\Delta^8$ -nonadecenyl acetate, b.p. 172—174°/0.06 mm., m.p. 21°, reduced and hydrolysed by  $\text{Al}(\text{OPr}^i)_3$  to  $\Delta^8$ -nonadecene- $\alpha$ - $\beta$ -diol, b.p. 158—161°/0.005 mm., whence olealdehyde, b.p. 108—110°/0.01 mm. (2:4-dinitrophenylhydrazones, m.p. 67—68°).  $\Delta^8$ -Undecenoic acid is converted by  $\text{SOCl}_2$  into the corresponding chloride, b.p. 119°/10 mm., which yields crude  $\alpha$ -diazododecen- $\beta$ -one, m.p. about 16°, whence  $\beta$ -keto- $\Delta^8$ -dodecenyl acetate, m.p. 52°,  $\Delta^8$ -dodecene- $\alpha$ - $\beta$ -diol, m.p. 48°, and undecenaldehyde, b.p. 101—103°/10 mm. (2:4-dinitrophenylhydrazones, m.p. 91° (Berl); semicarbazone], which forms a dimeride, m.p. 26°, when exposed to air. *d*-Citronellal acid gives  $\beta$ -keto- $\alpha$ -dimethyl- $\Delta^7$ -octenyl acetate, b.p. 140—141°/10 mm.,  $[\alpha]_D +5.1^\circ$ , reduced  $[\text{Al}(\text{OPr}^i)_3]$  to  $\delta$ -dimethyl- $\Delta^7$ -octene- $\alpha$ - $\beta$ -diol, b.p. 156—160°/14 mm., whence *d*-citronellal, b.p. 102—105°/12 mm.,  $[\alpha]_D +9.6^\circ$  (2:4-dinitrophenylhydrazones, m.p. 76.5°).  $\text{COPh} \cdot \text{CHN}_2$  affords phenylglycol, m.p. 67°, and thence PhCHO. Elaidic acid (I) is converted into  $\alpha$ -diazononadecan- $\beta$ -one, m.p. 53°,  $\beta$ -keto- $\Delta^8$ -nonadecenyl acetate, m.p. 62°,  $\Delta^8$ -nonadecene- $\alpha$ - $\beta$ -diol, m.p. 50°, and elaidaldehyde, m.p. 33° (semicarbazone, m.p. 92°; 2:4-dinitrophenylhydrazones, m.p. 90°), oxidised by  $\text{Ag}_2\text{O}$  to (I).  $\Delta^8$ -Hexenyl chloride gives  $\beta$ -keto- $\Delta^8$ -heptenyl acetate, b.p. 112—115°/12 mm., reduced by Na-Hg in aq. MeOH to  $\Delta^8$ -hepten- $\alpha$ - $\beta$ -diol, b.p. 122—124°/12 mm., whence  $\Delta^8$ -hexenaldehyde (2:4-dinitrophenylhydrazones, m.p. 147°). Dihydropyruconyl dichloride gives  $\alpha$ -bisdiazononadecene- $\beta$ - $\gamma$ -dione, m.p. 75°, whence  $\alpha$ -diacetoxy- $\Delta^8$ -octene- $\beta$ - $\gamma$ -dione (II), m.p. 91°, transformed by Br in  $\text{CHCl}_3 \cdot \text{CCl}_4$  into  $\delta$ -dibromo- $\alpha$ -diacetoxyoctane- $\beta$ - $\gamma$ -dione, m.p. 110° (decomp.), which with warm  $\text{C}_6\text{H}_5\text{N}$  yields  $\alpha$ -diacetoxy- $\Delta^7$ -octadiene- $\beta$ - $\gamma$ -dione, m.p. 133°. Reduction of (II) by Na-Hg in aq. dioxan yields non-cryst.  $\alpha$ - $\beta$ -tetra-acetoxy- $\Delta^8$ -octene, oxidised by

$\text{Pb}(\text{OAc})_4$  in AcOH to readily polymerised dihydropyruconaldehyde [*di*-*p*-nitrophenylhydrazones, m.p. 237° (decomp.)].  $\text{CHPh} \cdot \text{CH} \cdot \text{COCl}$  and  $\text{CH}_2\text{N}_2$  in  $\text{Et}_2\text{O}$  afford the very unstable 5-diazoacetyl-4-phenylpyrazoline, m.p. 80—81° (decomp.). H. W.

**Constitution of the coloured compound characteristic of the Rothera, Engfeldt, and Raurich Sas reaction of acetone.** F. E. RAURICH SAS (Anal. Fis. Quím., 1934, 32, 985—1006; cf. this vol., 1140).—The colour is attributed to a mixture of  $\text{Na}_2[\text{Fe}^{\text{II}}(\text{CN})_4(\text{NH}_2 \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})(\text{NH}_2)] \cdot \text{H}_2\text{O}$  and  $\text{Na}_2[\text{Fe}^{\text{II}}(\text{CN})_4(\{\text{NH}_2 \cdot \text{CMe}_2 \cdot \text{CH}_2\}_2\text{CO})] \cdot 2\text{H}_2\text{O}$ , of which the latter is isolated from  $\text{COMe}_2$  with conc.  $\text{NH}_3$  and 10%  $\text{Na}_2[\text{Fe}(\text{CN})_5(\text{NO})]$  and is decomposed to  $\text{Na}_2[\text{Fe}^{\text{II}}(\text{CN})_4(\text{NH}_2 \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})(\text{H}_2\text{O})] \cdot \text{H}_2\text{O}$  and  $\text{Na}_2[\text{Fe}^{\text{II}}(\text{CN})_4(\text{NH}_2 \cdot \text{CMe}_2 \cdot \text{OH})(\text{H}_2\text{O})]$ . The function of  $(\text{NH}_4)_2\text{SO}_4$  in the reaction combines dehydration, catalysis, and salting out.  $\text{CN}'$  is determined by distilling the sample in a current of  $\text{CO}_2$  with dil.  $\text{H}_3\text{PO}_4$  into 0.1*N*- $\text{AgNO}_3$  in dil.  $\text{HNO}_3$ , followed by titration with 0.1*N*- $\text{KCN}$ . F. R. G.

**Constitution of the coloured compounds formed in Rimini's reaction for acetone and some of its variations.** F. E. RAURICH SAS (Anal. Fis. Quím., 1934, 32, 1187—1216).—The complexes formed by  $\text{COMe}_2$ ,  $\text{Na}_2[\text{Fe}(\text{CN})_5(\text{NO})]$ , and amines are discussed. The following are isolated:  $\text{NH}_2\text{Me}$  gives  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{NHMe} \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})_2] \cdot 2\text{H}_2\text{O}$ ;  $\text{NHMe}$  yields  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{NHMe})_2] \cdot \text{H}_2\text{O}$ ;  $\text{NH}_2\text{Et}$  gives  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{NHEt} \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})_2] \cdot 2\text{H}_2\text{O}$  and  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{NHEt} \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})(\text{NH}_2\text{Et})] \cdot \text{H}_2\text{O}$ ;  $(\text{CH}_2 \cdot \text{NH})_2$  produces  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{NH}_2 \cdot \text{CH}_2 \cdot \text{CH} \cdot \text{NH} \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})] \cdot \text{H}_2\text{O}$  and  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{CH}_2 \cdot \text{NH} \cdot \text{CMe}_2 \cdot \text{CH}_2\text{Ac})_2] \cdot 2\text{H}_2\text{O}$ , whilst piperazine gives  $\text{Na}_2[\text{Fe}(\text{CN})_4(\text{C}_4\text{H}_{10}\text{N}_2)] \cdot 1.2\text{H}_2\text{O}$ . F. R. G.

**Electrolytic reduction of organic compounds at the dropping mercury electrode.** II. A. WINKEL and G. PROSKE (Ber., 1936, 69, [B], 1917—1929; cf. this vol., 709).—Measurements are recorded for many diketone-compounds, saturated dicarboxylic acids, OH-CO substances, halogen derivatives of PhCHO, and phenolic aldehydes. The magnitude of the potential displacement cannot be quantitatively given since it depends on the abs. val. of the reduction potential. The relative activity of the individual groups is readily deduced. Activating groups arranged in order of decreasing effect are  $\text{CH}_2\text{I}$ ,  $\text{CH}_2\text{Br}$ ,  $\text{CH}_2\text{Cl}$ ,  $\text{C}_{10}\text{H}_7$  (*k*), Ph (*k*), Ac,  $\text{CO}_2\text{H}$ ,  $\text{C}_6\text{H}_4\text{Cl-o}$ ,  $\text{C}_6\text{H}_4\text{Cl-m}$ ,  $\text{C}_6\text{H}_4\text{Cl-p}$ ,  $\text{C}_6\text{H}_4\text{Br-m}$ ,  $\text{C}_6\text{H}_4\text{Br-p}$ ,  $\text{CH}_2 \cdot \text{OH}$ ,  $\text{CH}_2\text{Ac}$  whereas stabilising groups are Me,  $\text{NH}_2$ , OH. The activity of groups *k* is due exclusively to the conjugated double linkings caused by introduction of the groups into the reducible mol. The most active conjugation is shown by compounds with quinonoid structure. Repeated introduction of a substituent increases its effect but the degree does not correspond with the no. of substituents. A correlation of reduction potential with absorption and Raman spectrum is indicated. H. W.

**Thermal mutarotation of *d*-galactose, *l*-arabinose, and *d*-talose.**—See this vol., 1209.

Colour reaction of hexoses and their polymerides, and its application to colorimetric determination of glucose in blood. M. Pozzi-Escot (J. Pharm. Chim., 1936, [viii], 24, 121).—A claim of priority in respect of the reaction described by Sanchez (this vol., 709). W. O. K.

Hydrolysis of acetylated carbohydrates. G. ZEMPLÉN, A. GERECs, and I. HADÁCSY (Ber., 1936, 69, [B], 1827—1829).—Zemplén's method can be applied in cases in which the Ac derivative and parent substance are insol. in the medium. Thus cellulose acetate (38% OAc) is completely hydrolysed with about 6% of the amount of Na (in boiling MeOH) which is required for complete removal of Ac as NaOAc. The process is little influenced by the duration of heating, greatly by the amount of Na. The method can also be used with reducing sugars which are very sensitive to warm alkali; thus cellobiose octa-acetate is hydrolysed at room temp. by NaOMe in MeOH (about half the amount necessary if CHCl<sub>3</sub> is used) to cellobiose in 85% yield. H. W.

Rotatory power of sugar hydrazones in relation to the stereochemical structure of the  $\alpha$ -carbon atom. II. E. VOTOČEK and Z. ALLAN. III. E. VOTOČEK and O. WICHTERLE (Coll. Czech. Chem. Comm., 1936, 8, 313—321, 322—326; cf. A., 1931, 938).—II. *p*-Tolylhydrazine with CH<sub>2</sub>PhCl at 140—145° affords *p*-tolylbenzylhydrazine, m.p. 37—38° (hydrochloride), and some benzaldehyde-*p*-tolylbenzylhydrazone, m.p. 137—138°. The *p*-tolylbenzylhydrazones (m.p. in parenthesis) of the following are prepared: *d*-xylose (96—97°; [ $\alpha$ ]<sub>D</sub> -22.5°); *d*-arabinose (170—171°; [ $\alpha$ ]<sub>D</sub> +9.6°); *l*-rhamnose (129—130°; [ $\alpha$ ]<sub>D</sub> -11°); *l*-fucose (183°; [ $\alpha$ ]<sub>D</sub> +33.3°); *d*-glucose (169.5—170.5°; [ $\alpha$ ]<sub>D</sub> -23.2°  $\rightarrow$  -18.6° in 24 hr.); *l*-mannose (160—161°; [ $\alpha$ ]<sub>D</sub> +31.6°); and *d*-galactose (160.5—161.5°; [ $\alpha$ ]<sub>D</sub> -9.0°); all rotations are in MeOH. The *p*-tolylbenzylhydrazones of glyoxal and *d*-fructose have m.p. 221° and 132—133°, respectively. The *p*-tolylbenzylhydrazones of the following are prepared: *o*-, m.p. 118—119°, *m*-, m.p. 151°, and *p*-OH-C<sub>6</sub>H<sub>4</sub>-CHO, m.p. 173—174°; anisaldehyde, m.p. 132—133°; vanillin, m.p. 152—153°; piperonal, m.p. 143°. The *p*-tolylbenzylhydrazones of the sugars follow Hudson's rule and can be used to determine the stereochemical configurations at the  $\alpha$ -C.

III. NPhPh-NH<sub>2</sub> with CH<sub>2</sub>Ph-CH<sub>2</sub>Cl at 145—160° affords phenyl- $\beta$ -phenylethylhydrazine, m.p. 54—56° (hydrochloride). The phenyl- $\beta$ -phenylethylhydrazones (I) of the following are prepared (m.p. in parenthesis): PhCHO (109°); *d*-arabinose (140—142°; [ $\alpha$ ]<sub>D</sub> +1.5°); *l*-rhamnose (121°; [ $\alpha$ ]<sub>D</sub> -9.95°); *l*-fucose (179°; [ $\alpha$ ]<sub>D</sub> +7.4°  $\rightarrow$  +6.3° in 20 hr.); *d*-glucose (142°; [ $\alpha$ ]<sub>D</sub> +5.2°); *d*-mannose (157°; [ $\alpha$ ]<sub>D</sub> +18.1°); and *d*-galactose (157°; [ $\alpha$ ]<sub>D</sub> +2.7°  $\rightarrow$  +7.0° in 3 days); all rotations are in MeOH. The "benzyl rule" (see above) cannot be applied to (I). J. L. D.

Acetylation of carbohydrates. Catalytic acetylation of glucose with small amounts of perchloric acid. D. KRUGER and W. ROMAN (Ber., 1936, 69, [B], 1830—1834).—Glucose (I) is not acetylated by AcOH-Ac<sub>2</sub>O in absence of a catalyst at low

temp. but the  $\alpha$ -penta-acetate is readily produced in the presence of very small amounts of HClO<sub>4</sub>. The behaviour of (I) is essentially similar to that of cellulose. Since reaction occurs to only a very limited extent with AcOH in presence of a catalyst or dehydrating agent, acetylation is due to Ac<sub>2</sub>O and the change is ROH+Ac<sub>2</sub>O=ROAc+AcOH; free H<sub>2</sub>O is not intermediately produced. Reaction is considered to proceed through a "crit. complex" of catalyst, acetylating agent, and reactive group. H. W.

Photochemical reactions in the *o*-nitrobenzylidenacetals series. X. Benzylideneacetals of sugars and glucosides. I. TANASESCU and M. IONESCU. XI. Benzylideneacetals of sugars and glucosides. Their transformation into diastereoisomerides. I. TANASESCU and E. CRACIUNESCU (Bull. Soc. chim., 1936, [v], 3, 1511—1517, 1517—1527; cf. this vol., 593).—X. Glucose, *o*-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-CHO, and P<sub>2</sub>O<sub>5</sub> at 40—50° give 1:2:4:6- or 1:3:4:6-di-*o*-nitrobenzylideneglucose, m.p. 125—130°, [ $\alpha$ ] 0°, stable to hydrolysing and acylating agents, converted in CHCl<sub>3</sub> or C<sub>6</sub>H<sub>6</sub> by light into 1:2- or 1:3-*o*-nitrobenzylideneglucose 4-*o*-nitrosobenzoate (I), m.p. 145°, [ $\alpha$ ] 0°, the presence of the free 6-OH being proved by formation of a 6-benzoate, m.p. 145°, -benzene-, m.p. 145°, and -*p*-toluene-sulphonate, m.p. 140°, and that of the NO by condensation to yield a phenylazo-, m.p. 124°, and dimedon derivative, m.p. 163°. Similarly are obtained 2:3:4:6-di-*o*-nitrobenzylidene- $\alpha$ -methylglucoside, m.p. 95—100°, and 2:3-*o*-nitrobenzylidene- $\alpha$ -methylglucoside 4-*o*-nitrosobenzoate, m.p. 135°. Di-*m*-nitrobenzylideneglucose, m.p. 105—110°, is stable to light.

XI. Di-*o*-nitrobenzylidene-glucose, -mannose, and -galactose give in light the same NO-compound (I) owing to inversion, and with Dimroth's reagent all give galactose (characterised as osazone). Di-*o*-nitrobenzylidene- $\alpha$ -mannoside, m.p. 125—130°, gives 2:3-*o*-nitrobenzylidene- $\alpha$ -methylmannoside 4-*o*-nitrosobenzoate, m.p. 117°. R. S. C.

Two forms of methylated derivatives of sorbose. G. ARRAGON (Bull. Soc. Chim. biol., 1936, 18, 1336—1343).—Methylation of methylsorbose gave two pentamethylsorbosides, (I) b.p. 48—49°/10<sup>-4</sup> mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> -31.5° in MeOH and (II), b.p. 48—49°/10<sup>-4</sup> mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> -11.8° in MeOH. On hydrolysis (I) gave tetramethylsorbose (III), b.p. 51°/10<sup>-4</sup> mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> +4.9° in MeOH and (II) tetramethylsorbose (IV), b.p. 51°/10<sup>-4</sup> mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> +3.6° in MeOH. Treatment of either (III) or (IV) with Ag<sub>2</sub>O and MeI gave the Me<sub>5</sub> derivative from which it was derived by hydrolysis; with Me<sub>2</sub>SO<sub>4</sub> only (II) was obtained. The mol. refractions of the compounds suggest that they have ring structures. H. D.

Influence of the aglucone on rate of hydrolysis of  $\beta$ -glucosides by emulsin.—See this vol., 1297.

Synthesis of glucosides. I—III. K. SISO (J. Soc. Chem. Ind. Japan, 1936, 39, 217—218b).—I. II. The reaction of PhOH etc. with sugar acetates in presence of *p*-C<sub>6</sub>H<sub>4</sub>Me-SO<sub>3</sub>H to form phenolglucosides is facilitated by working at very high vac., when AcOH is removed as liberated. In this way,  $\beta$ -

glucose penta-acetate with PhOH gives  $\beta$ -phenol-glucoside tetra-acetate (70%) (also obtained using  $\text{ZnCl}_2$ ); with quinol, arbutin penta-acetate (60%); with  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ , helicin acetate; and with  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ , salicylic acid  $\beta$ -glucoside acetate.

III. Sucrose octa-acetate with PhOH and  $\text{ZnCl}_2$  yields  $\alpha$ -phenolglucoside tetra-acetate. E. W. W.

**Non-hydrolysable  $\beta$ -glucoside.** S. VEIBEL and E. NEILSEN (Compt. rend., 1936, 203, 126—128).—Acetobromoglucose with  $\text{Bu}^n\text{OH}$  and  $\text{Ag}_2\text{CO}_3$  affords *trimethylcarbinol- $\beta$ -d-glucoside tetra-acetate*, m.p. 145—146° (corr.),  $[\alpha]_D^{20}$  —19.3° in EtOH, converted ( $\text{NaOMe}$ ) into the *glucoside*, m.p. 164—166°,  $[\alpha]_D^{20}$  —19.0° in  $\text{H}_2\text{O}$ , which is hydrolysed ( $k=2\times 10^{-4}$ ) at 0.005 times the rate of  $\beta$ -methylglucoside ( $k=3.9\times 10^{-2}$ ).

J. L. D.

**$\beta$ -d-Glucosides of caffeic and ferulic acids.** B. HELFERICH and F. VORSATZ (J. pr. Chem., 1936, [ii], 145, 270—272).—The prep. of  $\beta$ -d-glucosido-caffeic acid ( $+\text{H}_2\text{O}$ ), m.p. 145°, (anhyd.)  $[\alpha]_D^{20}$  —80° in  $\text{H}_2\text{O}$  and —114° in 0.5N-NaOH (cf. A., 1935, 489), and of  $\beta$ -d-glucosidoferulic acid, m.p. 231—232°,  $[\alpha]_D^{20}$  —41.5° in  $\text{C}_6\text{H}_5\text{N}$  ( $\text{Ac}_4$  derivative,  $[\alpha]_D^{20}$  —32.9° in  $\text{CHCl}_3$ ) (cf. A., 1934, 1003), by the modified Knoevenagel method (this vol., 1251) is described.

H. G. M.

**Thevetin.** R. C. ELDERFIELD (J. Biol. Chem., 1936, 115, 247—252).—Thevetin (I),  $\text{C}_{29}\text{H}_{44}\text{O}_{13}$  (cf. lit.), softens at 193—194°, decomp. 210°, affords glucose with hot 3%  $\text{H}_2\text{SO}_4$ , and with  $\text{NaOH-MeOH}$  gives *isothetvetin*, sinters at 180°, decomp. 200—210°,  $[\alpha]_D^{20}$  —60° in  $\text{C}_6\text{H}_5\text{N}$ ; this is hydrolysed by 2%  $\text{HCl}$  to *isothetvetogenin*,  $\text{C}_{23}\text{H}_{34}\text{O}_8$ ,  $+\text{H}_2\text{O}$ , sinters at 170°, decomp. about 220°, and with  $\text{NaOBr}$  gives *isothetvetinic acid* (not obtained pure), which is hydrolysed by  $\text{HCl}$  to *isothetvetogenic acid*,  $\text{C}_{23}\text{H}_{34}\text{O}_9$ , decomp. 120—130°. These reactions, the nitroprusside reaction, and absorption of 1  $\text{H}_2$  on hydrogenation support the formula assigned above to (I). Most of the derivatives form gels except in presence of mineral salts.

R. S. C.

**Characterisation of starch by dispersoid analysis.**—See this vol., 1201.

**Hemimethylcellulose.** R. PIWONKA (Ber., 1936, 69, [B], 1965—1968; cf. this vol., 971).—Treatment of ramie fibres with 4.12N-NaOH and  $\text{CuCl}_2$  and of the product (I) with  $\text{Me}_2\text{SO}_4$  gives a hemimethylcellulose, hydrolysed (Irvine-Hirst) to a methylmethylglucoside (II), b.p. 156°/0.1 mm. Treatment of (II) with 5% aq.  $\text{HCl}$  and then with  $\text{NHPh}\cdot\text{NH}_2$  in  $\text{AcOH}$  gives a methylglucosazone, m.p. 178—180°, showing that Me is not present at position 2. Oxidation of (II) with  $\text{HNO}_3$  ( $d$  1.2) and esterification of the product gives *Et<sub>2</sub> methylsaccharate*, b.p. 161°/2 mm., and *Et methylsaccharolactonate*, b.p. 184°/1.5 mm., m.p. 103—104°,  $[\alpha]_D^{20}$  +8.1°. It follows therefore that the sugar derivatives contain Me at 3 and that in the methylation of (I) the entry of Me into the glucose group of cellulose occurs exclusively in this position.

H. W.

**Alkaline decomposition of cellulose nitrate.** I. QUANTITATIVE. W. O. KENYON and H. LE B. GRAY (J. Amer. Chem. Soc., 1936, 58, 1422—1427).—

Hydrolysis (1—20%  $\text{NaOH}$ ) of cellulose nitrate (I) at 30—60° gives a little  $\text{Na}_2\text{CO}_3$ , much  $\text{NaNO}_2$ , and some reducing substances (II). The production of  $\text{CO}_2$  and (II) is related to time, temp., alkali concn., and ratio of  $\text{NaOH}$  to (I). Quant. data are given.

H. B.

**System methylamine-calcium chloride.**—See this vol., 1204.

**Optical rotations in homologous series of aliphatic amines.** P. A. LEVENE and R. E. MARKER [with M. KUNA] (J. Biol. Chem., 1936, 115, 267—274).—Amines,  $\text{NH}_2\cdot[\text{CH}_2]_m\cdot\text{CHMe}\cdot[\text{CH}_2]_n\cdot\text{Me}$ , exactly resemble the corresponding alcohols in variations of  $[M]$ , but their hydrochlorides resemble the corresponding acids.  $[M]$  given below are max.  $[M]^{25}$  (homogeneous) unless otherwise stated. *d*- $\beta$ -Methyl-*n*-valeronitrile and  $\text{H}_2$ -Raney Ni in  $\text{MeOH}$  give *d*- $\gamma$ -methyl-*n*-amylamine,  $[M]$  +10.9° in 44%  $\text{EtOH}$  (hydrochloride,  $[M]$  +9.85° in  $\text{H}_2\text{O}$ ). Similarly are prepared *d*- $\delta$ -methyl-*n*-hexyl-, b.p. 80°/90 mm.,  $[M]$  +11.7° (hydrochloride,  $[M]$  +13.2° in  $\text{H}_2\text{O}$ ), *d*- $\epsilon$ -methyl-*n*-heptyl-,  $[M]$  +16° in 60%  $\text{EtOH}$  (hydrochloride,  $[M]$  +15.7° in  $\text{H}_2\text{O}$ ), *d*- $\delta$ -methyl-*n*-heptyl-, b.p. 165°,  $[M]$  +0.68°, *l*- $\beta$ -methyl-*n*-hexyl-,  $[M]$  —16.4° in  $\text{Et}_2\text{O}$  (hydrochloride,  $[M]$  —18.2° in  $\text{MeOH}$ ), *l*- $\gamma$ -methyl-*n*-heptyl-, b.p. 65—66°/14 mm.,  $[M]$  —1.72° (hydrochloride,  $[M]$  +2.13° in  $\text{MeOH}$ ), *l*- $\delta$ -methyl-*n*-octyl-, b.p. 75—77°/13 mm.,  $[M]$  —0.78° (hydrochloride,  $[M]$  —0.63° in  $\text{MeOH}$ ), *l*- $\epsilon$ -methyl-*n*-nonyl-, b.p. 92°/15 mm.,  $[M]$  —0.75° (hydrochloride,  $[M]$  —1.15° in  $\text{MeOH}$ ), and *l*- $\zeta$ -methyl-*n*-decyl-amine, b.p. 113°/15 mm.,  $[M]$  —2.44° (hydrochloride,  $[M]$  —3.47° in  $\text{H}_2\text{O}$ ).

R. S. C.

**Identification of hexamethylenetetramine and ammonia.** G. BOUVILLOUX (J. Pharm. Chim., 1936, [viii], 24, 58—64).— $(\text{CH}_2)_6\text{N}_4$  may be used to identify  $\text{CH}_2\text{O}$ , phenols, piperonal, and iodides.

F. N. W.

**Determination of choline.** I. SAKAKIBARA and T. YOSINAGA (J. Biochem. Japan, 1936, 23, 211—239).—The following methods were investigated: pptn. by  $\text{HgCl}_2$  from  $\text{EtOH}$  solution and determination (Kjeldahl) of N in the ppt.; pptn. by  $\text{AuCl}_3$  in  $\text{EtOH}$  and determination of N in the ppt.; Levene-Ingvaldsen method (A., 1920, ii, 713); Roman's method (A., 1930, 752). None of these methods is applicable to choline (I)-lecithin (II) mixtures. Attempts to remove (II) by  $\text{COMe}_2$ , or salts  $[\text{MgCl}_2, \text{CaCl}_2, \text{Fe}(\text{OH})_3, \text{Fe citrate}]$  and their mixtures indicated the following method: (II) is pptd. by aq.  $\text{Fe citrate}$  followed by aq.  $\text{Fe citrate-Fe}(\text{OH})_3$ , the ppt. is separated, and (I) is determined in the filtrate by Roman's method.

F. O. H.

**Colorimetric micro-determination of choline and acetylcholine.** F. J. R. BEATTIE (Biochem. J., 1936, 30, 1554—1559; cf. Kapfhammer *et al.*, A., 1930, 1464).—Choline (I) and acetylcholine (II) are pptd. as reineckate, the colour of which, after dissolution in  $\text{COMe}_2$ , is compared with that of a standard, but (II) is best hydrolysed to (I) before determination. Carnitine, but not other common biological material, interferes. 0.03 mg. of (I) (concn. 0.003%) can be determined with an error of  $\pm 3\%$ .

W. McC.

**Action of hypochlorites on amino-acids and proteins. Effect of acidity and alkalinity.** N. C. WRIGHT (Biochem. J., 1936, 30, 1661—1667).—Between  $p_H$  6 and 11 the quantity of Cl capable of liberating I from KI in a 0.014% NaOCl solution decreases with the amount of glycine (I) added and reaches zero at a concn. of approx. 0.005%; with greater concns. the available Cl increases  $\propto$  the concn. of (I). The rate of this increase depends on the  $p_H$  attaining a max. at  $p_H$  8.8. At very acid  $p_H$  the available Cl never falls to zero and no subsequent rise with increasing concn. of (I) occurs. Cystine produces only the decrease with the amount added and no subsequent rise; in alkaline solution the reaction is associated with polysulphide formation. The fact that large quantities of  $NH_2$ -acid cause a smaller reduction in available Cl than small quantities is explained by assuming that NaOCl in low concn. acts as a chlorinating agent and only as an oxidant when present in relative excess. The behaviour of caseinogen and gelatin under the same conditions showed similarities to that of the  $NH_2$ -acids; in addition a ppt. was formed with gelatin which on treatment with KI liberated I. The purely oxidative theory of NaOCl action of Norman (this vol., 595) is criticised. H. D.

**Interaction of ethyl  $\alpha$ -chlorocrotonate and dimethylamine.** J. C. ROBERTS (J.C.S., 1936, 1169—1170).—Et  $\alpha$ -bis(dimethylamino)butyrate, b.p. 89°/3 mm., 91°/6 mm. [monohydrochloride, m.p. 117°; picrate, m.p. 147°; platinichloride, m.p. 180° (decomp.)], is prepared from Et  $\alpha$ -chlorocrotonate (1 mol.) and  $NHMe_2$ -abs. EtOH. Attempts to prepare the dimethiodide of the base failed. J. T. A.

**Preparation and activation of homoaspartic acid.** P. PFEIFFER and E. HEINRICH (J. pr. Chem., 1936, [ii], 146, 105—112).— $CH_3Ac \cdot CO_2Et$ ,  $(NH_4)_2CO_3$ , and KCN in 50% EtOH under  $CO_2$  at 70—80°/20 atm. afford Et 5-methylhydantoin-5-acetate, m.p. 138° [corresponding amide, m.p. 252° (decomp.)], and hydrazide, m.p. 104—105°, converted by boiling 40% KOH into  $\beta$ -aminopropane- $\alpha$ -dicarboxylic (homoaspartic) acid (I), m.p. 233° (decomp.) [hydrochloride, m.p. 212° (decomp.)]; Ca (also +3H<sub>2</sub>O), Ba (also +4H<sub>2</sub>O), Pb (also +2H<sub>2</sub>O), and Cu (also +3H<sub>2</sub>O) salts; Ac derivative, m.p. 156—157°; corresponding diamide, m.p. 173°. (I) and NaNO<sub>2</sub> in HCl yield  $\beta$ -hydroxypropane- $\alpha$ -dicarboxylic acid, m.p. 119°. Resolution of (I) by strychnine in H<sub>2</sub>O gives the corresponding d-acid, m.p. 240°,  $[\alpha]_D^{20} +3.55^\circ$  in H<sub>2</sub>O [strychnine salt (also +2H<sub>2</sub>O), decomp. about 302° after becoming discoloured at 210°,  $[\alpha]_D^{24} -28.67^\circ$ ], and the l-acid,  $[\alpha]_D -3.66^\circ$  in H<sub>2</sub>O. H. W.

**Resolution of dl-lysine.** C. P. BERG (J. Biol. Chem., 1936, 115, 9—15).—dl-Lysine yields l-(+)-lysine d- (I), m.p. 245—246°,  $[\alpha] +16.41^\circ$ , and l-camphorate, m.p. 239—240°,  $[\alpha] +0.35^\circ$ , and d-(−)-lysine d-, m.p. 239—240°,  $[\alpha] -0.38^\circ$ , and l-camphorate (II), m.p. 245—246°,  $[\alpha] -16.39^\circ$ , and thence l-(+)-lysine and d-(−)-lysine dihydrochloride, m.p. 201—202°,  $[\alpha] -15.65^\circ$ . (I) and (II) are the less sol. salts. M.p. are corr. and  $[\alpha]$  are  $[\alpha]_D^{20}$  in H<sub>2</sub>O. R. S. C.

**Determination of creatinine with sodium 3:5-dinitrobenzoate.** W. D. LANGLEY and M.

EVANS (J. Biol. Chem., 1936, 115, 333—341).—Procedure similar to that of Benedict and Behre (this vol., 1013) is described. H. D.

**Reversible transfer of phosphate between the adenylic acid system and phosphagens.** H. LEHMANN (Biochem. Z., 1936, 286, 336—343).—Tables and curves show that the reversible esterification of adenylypyrophosphoric acid with arginine or with creatine (I) to give respectively adenosine diphosphate (II) + argininephosphoric acid or (II) + creatine phosphate (III) follow the mass law and give bimol. equilibrium consts. The same probably holds for (II) + (I) giving adenylic acid + (III). P. W. C.

**Diamino-acid, canavanine. IV. Constitution of canavanine and canaline.** M. KITAGAWA and A. TAKANI (J. Biochem. Japan, 1936, 23, 181—185).—Dibenzoylcanaline with 7% HCl at 100° affords  $\alpha$ -benzoylcanaline, m.p. 150°, which on keeping with O-methylisocarbamide in MeOH at room temp. (Kapfhammer and Muller, A., 1934, 876) yields  $\alpha$ -benzoylcanavanine. The properties of normal and guanidated O-hydroxylamineacetic acid (from condensation of benzhydroximic acid and  $CH_2Br \cdot CO_2Et$ ; cf. Werner, A., 1893, i, 510) confirm the indication of the above synthesis that canaline is  $NH_2O \cdot CH_2 \cdot CH_2 \cdot CH(NH_2) \cdot CO_2H$  and canavanine is  $NH_2 \cdot C(NH_2) \cdot NH \cdot O \cdot CH_2 \cdot CH_2 \cdot CH(NH_2) \cdot CO_2H$  (cf. A., 1934, 993). F. O. H.

**Synthesis of peptides containing cystine and glutamine; possible bearing on the structure of insulin. Amide nitrogen of insulin.** C. R. HARRINGTON and T. H. MEAD (Biochem. J., 1936, 30, 1598—1611).—Neither glutaminylcysteine (I) nor cysteylglutamine (II), in either the reduced or the oxidised forms, has hypoglycaemic activity. They resemble insulin in the lability of the amide-N, but their S is more stable to alkali. Insulin appears to have 34 amide groups per mol., indicating about 30% of glutamic acid. In the syntheses of (I) and (II), it is found that the intermediate compounds crystallise more readily as cysteine rather than cystine derivatives, and also that benzylcarboxyl esters are more convenient than benzyl esters, owing to the readier removal of the group with  $PH_4I$ . In the synthesis of (I), S-benzylcysteine and  $CH_2Ph \cdot COCl$  in 2M-NaOH give, on acidification, N-carbobenzylxy-S-benzylcysteine (III), m.p. 93—95°, which, converted into the acid chloride and added to  $\gamma$ -Et glutamate and  $NEt_3$  in H<sub>2</sub>O, gives  $\gamma$ -Et N-carbobenzylxy-S-benzylcysteylglutamate, m.p. 88°. Treatment with aq.  $NH_3$  and acidification yields N-carbobenzylxy-S-benzylcysteylglutamine, m.p. 188—189°, reduction of which with Na in liquid  $NH_3$  yields cysteylglutamine, which after purification via the  $Cu^I$  mercaptide has  $[\alpha]_{5461}^{20} +6.6^\circ$ . Oxidation with  $H_2O_2$  yields cystylglutamine,  $[\alpha]_{5461}^{20} -13.9^\circ$ . (III) is also obtained by Zn-Cu reduction of N-carbobenzylxycystine in EtOH- $H_2SO_4$  to N-carbobenzylxycysteine, m.p. 82°, which with  $CH_2PhBr$  in alkaline solution gives (III). In the synthesis of (II), N-carbobenzylxycystyl chloride with  $CH_2Ph \cdot OH$  gives the  $CH_2Ph$  ester, which with  $PH_4I$  in AcOH is converted into cysteine benzyl ester hydriodide, m.p. 139° (decomp.). This with N-carbobenzylxyglutamic anhydride in dry  $CHCl_3$  in presence

of  $\text{NHET}_2$  gives *N*-carbobenzyloxy- $\alpha$ -glutamylcysteine benzyl ester (IV), m.p. 148°, which with  $\text{CH}_2\text{PhBr}$  in  $\text{CHCl}_3\text{-NHET}_2$  gives *N*-carbobenzyloxy- $\alpha$ -glutamyl-S-benzylcysteine benzyl ester, m.p. 144°. This, after conversion into the acid chloride, gives the amide, m.p. 182°, and after removal of the substituent groups by Na in liquid  $\text{NH}_3$ , yields glutamylcysteine, decomp. 197°,  $[\alpha]_{5461} -9.8^\circ$ . Oxidation with  $\text{H}_2\text{O}_2$  gives glutamylcystine,  $[\alpha]_{5461} -119^\circ$ . Other substances described include glycine benzyl ester hydrochloride (V), m.p. 139–140°, from glycyl chloride hydrochloride and  $\text{CH}_2\text{Ph-OH}$  in  $\text{Et}_2\text{O}$ ; *N*-carbobenzyloxyglycylglycine benzyl ester, m.p. 167–168°, by removal of  $\text{HCl}$  from (V) and treatment with *N*-carbobenzyloxyglycyl chloride. Using instead the acid chloride from  $\alpha$ -benzyl *N*-carbobenzyloxyglutamate, the  $\alpha$ -benzyl ester of *N*-carbobenzyloxy- $\gamma$ -glutamylglycine benzyl ester, m.p. 104–105°, results. The acid chloride from *N*-carbobenzyloxyaspartic acid  $\alpha$ -benzyl ester, in  $\text{CHCl}_3$ , added with aq.  $\text{NaOH}$  to glycine, yields *N*-carbobenzyloxy- $\beta$ -aspartylglycine, m.p. 153°; the same acid chloride with cystine  $\text{Et}$  ester hydrochloride in  $\text{C}_6\text{H}_5\text{N}$  gives  $\alpha$ -benzyl-*N*-carbobenzyloxy- $\beta$ -aspartylcystine *Et* ester, m.p. 160°. (IV) with  $\text{CH}_2\text{N}_2$  at 0° gives  $\gamma$ -methyl-*N*-carbobenzyloxy- $\alpha$ -glutamyl-S-methylcysteine benzyl ester, m.p. 85–86°.

F. A. A.

**Alkyl- and aryl-amides and -carbamides as hypnotics.** E. H. VOLWILER and D. L. TABERN (J. Amer. Chem. Soc., 1936, 58, 1352–1354).—The following acids are prepared from the appropriate  $\text{CRR}'(\text{CO}_2\text{H})_2$ ; their derivatives are generally obtained by standard methods:  $\beta$ -methylhexoic acid, b.p. 208–210°/755 mm. (chloride, b.p. 83–85°/60 mm.);  $\alpha$ -bromo- $\beta$ -methylhexoic acid (chloride, b.p. 110–120°/40 mm.; amide, m.p. 112–114°; methylamide, m.p. 90°);  $\beta$ -methyl- $\alpha$ -ethylhexoic acid, b.p. 225–230°/755 mm. (chloride, b.p. 103–108°/45 mm., 190°/755 mm.; amide, m.p. 97–98°; methylamide; allylamide; diethylamide);  $\alpha$ -bromo- $\beta$ -methyl- $\alpha$ -ethylhexoic acid (chloride, b.p. 138–150°/50 mm.; amide);  $\beta$ -methylallylhexoic acid, b.p. 195–200°/755 mm. (chloride, b.p. 190–195°/755 mm.; amide, m.p. 90–91°);  $\beta$ -methyl- $\alpha$ -butylhexoic acid, b.p. 185–190°/55 mm. (chloride, b.p. 140°/55 mm.; amide, m.p. 97–98°);  $\alpha$ -ethylheptioic acid, b.p. 232–238°/750 mm. (chloride, b.p. 195–200°/750 mm.; amide, m.p. 96°);  $\beta$ -methyl- $\alpha$ -ethylvaleric acid (allylamide;  $\alpha$ -Br-derivative chloride, b.p. 130–135°/50 mm.);  $\alpha$ -isopropylbutyric acid (methylamide, m.p. 72–75°; ethylamide; allylamide, m.p. 58–60°);  $\alpha$ -phenyl- $\Delta^2$ -pentenoic acid (amide, m.p. 63°);  $\alpha\beta$ -diethylvaleric acid (amide, m.p. 123–125°). The requisite acyl chloride and an excess of  $\text{CO}(\text{NH}_2)_2$  at 110–135° give  $\beta$ -methylhexoyl, m.p. 180°,  $\alpha$ -bromo-methylhexoyl, m.p. 108–110°,  $\beta$ -methyl- $\alpha$ -ethylhexoyl, m.p. 133°,  $\alpha$ -bromo- $\beta$ -methyl- $\alpha$ -ethylhexoyl,  $\beta$ -methyl- $\alpha$ -allylhexoyl, m.p. 123°,  $\beta$ -methyl- $\alpha$ -butylhexoyl, m.p. 123°,  $\beta$ -methyl- $\alpha$ -ethylvaleryl, m.p. 172°,  $\alpha$ -phenyl- $\Delta^2$ -pentenoyl, m.p. 133–134°,  $\alpha\beta$ -diethylvaleryl, m.p. 148–150°, and  $\alpha$ -ethylheptoyl, m.p. 130°. carbamide.  $\alpha$ -Phenylbutyramide and diethylmalonalloylamic acid have m.p. 85–87° and 105°, respectively. Pharmacological data for some of the compounds are given.

H. B.

**Synthetic substrates for protein-digesting enzymes.** M. BERGMANN and W. F. ROSS (J. Amer. Chem. Soc., 1936, 58, 1503).— $\epsilon$ -Carbobenzyloxyamino- $\alpha$ -hippurylamidohexoamide (I), m.p. 212° (from the Me ester and  $\text{MeOH-NH}_3$ ), is reduced catalytically to  $\epsilon$ -amino- $\alpha$ -hippurylamidohexoamide (II) (hydrochloride, m.p. 248°), which is hydrolysed by tryptic proteinase (prep.: Waldschmidt-Leitz and Purr, A., 1929, 1338) at 8.8 to  $\text{NH}_2\text{Bz-CH}_2\text{-CO}_2\text{H}$ , lysine, and  $\text{NH}_3$ . (I) is similarly unaffected. Papain-HCN at  $pH$  5 hydrolyses one peptide linking of (II).

H. B.

**Micro-determination of carbamide without distillation.** F. RAPPAPORT and M. GUTMANN (Klin. Woch., 1935, 14, 1325–1326; Chem. Zentr., 1935, ii, 3553).— $\text{CO}(\text{NH}_2)_2$  is converted by urease into  $\text{NH}_4$  salts;  $\text{NH}_3$  is then determined by an indirect iodometric method.

H. N. R.

**Structure of carbamide.**—See this vol., 298.

**Fission (sulpholysis) of carbamide by sulphuric acid.** Simple preparation of amidosulphonic acid and imidosulphonates. P. BAUMGARTEN (Ber., 1936, 69, [B], 1929–1937).— $\text{CO}(\text{NH}_2)_2$  and excess of 100%  $\text{H}_2\text{SO}_4$  at 130–140° give  $\text{CO}_2$ ,  $\text{NH}_2\text{-SO}_3\text{H}$  (I), and  $\text{NH}_4\text{HSO}_4$ :  $\text{CO}(\text{NH}_2)_2 + \text{OH}\text{-SO}_3\text{H} = \text{NH}_2\text{-CO}_2\text{H}$  (II) + (I) and (II) =  $\text{NH}_3 + \text{CO}_2$ . The yield of (I) diminished with increasing amount of  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{S}_2\text{O}_7$  is produced either according to  $\text{CO}(\text{NH}_2)_2 + 4\text{H}_2\text{SO}_4 = \text{CO}_2 + 2\text{NH}_4\text{HSO}_4 + \text{H}_2\text{S}_2\text{O}_7$  or (I) +  $\text{H}_2\text{SO}_4 = \text{NH}_4\text{HS}_2\text{O}_7$ , the latter change being realisable with (I) as initial material. Sulpholysis occurs more readily with fuming  $\text{H}_2\text{SO}_4$  and is then preceded by sulphonation of  $\text{CO}(\text{NH}_2)_2$  to  $\text{NH}_2\text{-CO-NH-SO}_3\text{H}$ , the intermediate production of which enables 2 mols. of (I) to be formed from 1 mol. of  $\text{CO}(\text{NH}_2)_2$ , instead of 1 mol. as when  $\text{H}_2\text{SO}_4\text{-H}_2\text{O}$  is employed; this yield is nearly attained when the acid has the approx. constitution  $\text{H}_2\text{S}_2\text{O}_7$ . With oleum containing less  $\text{SO}_3$  the yield of (I) declines even when an excess of  $\text{SO}_3$  is present. The strongly exothermic reaction between  $\text{CO}(\text{NH}_2)_2$  and  $\text{H}_2\text{S}_2\text{O}_7$  is very violent;  $\text{CO}(\text{NH}_2)_2$  should therefore be first dissolved in  $\text{H}_2\text{SO}_4\text{-H}_2\text{O}$  or conc.  $\text{H}_2\text{SO}_4$ , the necessary amount of conc. oleum is then added with cooling, and the mixture is cautiously heated.  $\text{CO}(\text{NH}_2)_2\text{-H}_2\text{SO}_4$  (III) is decomposed at 140°;  $3(\text{III}) \rightarrow 2\text{CO}_2 + \text{NH}(\text{SO}_3\text{NH}_4)_2 + \text{CO}(\text{NH}_2)_2\text{-NH}_4\text{HSO}_4$ . Better yields (about 80%) of  $\text{NH}(\text{SO}_3\text{H})_2$  [best isolated as the  $(\text{NH}_4)_3$  or  $\text{K}_3$  salt] are obtained when  $\text{H}_2\text{SO}_4$  is added,  $4(\text{III}) + \text{H}_2\text{SO}_4 = 4\text{CO}_2 + 2\text{NH}(\text{SO}_3\text{NH}_4)_2 + (\text{NH}_4)_2\text{SO}_4$ . (I) and  $\text{NH}_2\text{-SO}_3\text{NH}_4$  give  $\text{NH}(\text{SO}_3\text{NH}_4)_2$ . H. W.

**Synthesis of  $\alpha$ -bromoisovalerylcarbamide.** T. ICHIKAWA (J. Pharm. Soc. Japan, 1935, 55, 727–731).— $\alpha$ -Bromoisovaleryl bromide and  $\text{CO}(\text{NH}_2)_2$  yield  $\alpha$ -bromoisovalerylcarbamide, m.p. 153–154°.

CH. ABS. (r)

**Reduction of nitroguanidine. VI. Promoter action of platonic chloride on Raney nickel catalyst.** E. LIEBER and G. B. L. SMITH (J. Amer. Chem. Soc., 1936, 58, 1417–1419).—The rate of reduction of nitroguanidine (in  $\text{H}_2\text{O}$ ) and of castor oil, linseed oil,  $\text{PhNO}_2$ , and  $\text{PhCHO}$  (in 95%  $\text{EtOH}$ ) by  $\text{H}_2$  and Raney Ni (I) is considerably accelerated by addition of a little  $\text{PtCl}_4$  immediately before hydrogen-

ation begins. The following reaction occurs between (I) and  $\text{H}_2\text{PtCl}_6$ :  $3\text{Ni} + 2\text{H}^+ + \text{PtCl}_6^{--} \rightarrow 3\text{Ni}^{++} + \text{Pt} + \text{H}_2 + 6\text{Cl}^-$ . H. B.

Optical rotations and rotatory dispersions in homologous series of aliphatic nitriles. P. A. LEVENE, A. ROTHEN, and R. E. MARKER [with M. KUNA] (J. Biol. Chem., 1936, 115, 253—266).—Variation of  $[\alpha]_D$  in the series,  $\text{CN} \cdot [\text{CH}_2]_m \cdot \text{CHMe} \cdot [\text{CH}_2]_n \cdot \text{Me}$ , is analogous to that in the corresponding carboxylic acid series, except for an irregularity when  $m=1$ . Rotatory dispersions are usually small, but probably always anomalous.  $[\alpha]$  given below are max.  $[\alpha]_D^{25}$  (homogeneous) unless otherwise stated. *l*- $\alpha$ -Methyl-*n*-butyric acid affords the nitrile, b.p. 127°,  $[\alpha] -24.7^\circ$ , by way of the chloride and amide. *d*- $\gamma$ -Methyl-*n*-hexylic bromide and KCN in aq. EtOH give *d*- $\beta$ -methyl-*n*-valeronitrile, b.p. 154°,  $[\alpha] +8.67^\circ$ . *d*- $\gamma$ -Methyl-*n*-hexoic acid gives the chloride, b.p. 80°/50 mm.,  $[\alpha] +19^\circ$ , and thence the amide,  $[\alpha] +19.1^\circ$  in 75% EtOH, and nitrile, b.p. 105°/100 mm.,  $[\alpha] +16.7^\circ$ . *d*- $\delta$ -Methyl-*n*-hexylic bromide gives *d*- $\delta$ -methyl-*n*-heptonitrile, b.p. 115—133°/98—100 mm.,  $[\alpha] +17.3^\circ$ . *l*- $\delta$ -Methyl-*n*-heptoic acid gives the chloride, b.p. 82°/30 mm.,  $[\alpha] -6.78^\circ$ , and nitrile, b.p. 125°/100 mm.,  $[\alpha] -2.01^\circ$ . *d*- $\alpha$ -Methyl-*n*-hexoic acid gives the nitrile, b.p. 75—77.5°/20 mm.,  $[\alpha] +50.5^\circ (+52.5^\circ \text{ in } \text{C}_7\text{H}_{16})$ . *d*- $\gamma$ -Methylheptic acid gives the nitrile, b.p. 48—52°/0.5 mm.,  $[\alpha] +5.97^\circ (+6.86^\circ \text{ in } \text{C}_7\text{H}_{16})$ . *d*- $\gamma$ -Methylheptyl bromide gives *d*- $\gamma$ -methyl-octonitrile, b.p. 119—120°/30 mm.,  $[\alpha] -2.44^\circ (-2.63^\circ \text{ in } \text{C}_7\text{H}_{16})$ . *l*- $\delta$ -Methyl-*n*-nonoic acid gives the chloride, b.p. 111°/14 mm.,  $[\alpha] -3.47^\circ$ , and amide,  $[\alpha] -1.6^\circ$  in 75% MeOH. *l*- $\delta$ -Methyl-*n*-octyl bromide gives *l*- $\delta$ -methyl-*n*-nononitrile, b.p. 96—102°/12 mm.,  $[\alpha] -5.32^\circ (-5.44^\circ \text{ in } \text{C}_7\text{H}_{16})$ . *l*- $\epsilon$ -Nonan- $\alpha$ -ol gives *l*- $\epsilon$ -methyl-*n*-nonyl bromide, b.p. 110°/15 mm.,  $[\alpha] -5.3^\circ$ , and *l*- $\epsilon$ -methyl-*n*-deconitrile, b.p. 116—118°/15 mm.,  $[\alpha] -1.95^\circ (-1.95^\circ \text{ in } \text{C}_7\text{H}_{16})$ . R. S. C.

Polymerisation of  $\alpha$ -methylacrylonitrile. E. MERTENS and M. FONTEYN (Bull. Soc. chim. Belg., 1936, 45, 438—444).—The optimum temp. of polymerisation is 64°; no polymerisation occurs at <60° or >69°. Hot 60%  $\text{HNO}_3$ , alone of many acids, reacts probably by oxidation.  $\text{CaO}$  and  $\text{Ca}(\text{OH})_2$  polymerise the nitrile. A series of physical properties of the polymeride is given. J. L. D.

Action of hydrogen fluoride on diazoheptane. C. L. TSENG and T. S. HO (J. Chinese Chem. Soc., 1936, 4, 335—339).—*n*-Heptylcarbamide (modified prep.) with  $\text{HNO}_2$  yields nitrosoheptylcarbamide, m.p. 69.2—72.2°, which with 50% aq. KOH (<1°) gives diazoheptane. The latter with anhyd. HF forms  $\Delta^8$ -heptene. F. N. W.

Chromous and chromic ammines.—See this vol., 1218.

Use of organo-sodium compounds in organic syntheses. G. V. TSCHELINCEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 269—273).—A survey. J. T. A.

Aromatisation of cyclopentane homologues and paraffins in presence of platinised charcoal. B. A. KASANSKI and A. F. PLATE (Ber., 1936, 69,

[B], 1862—1869).—In contrast with the behaviour of cyclopentane and its Me, Et, and Pr derivatives *n*-butylcyclopentane is converted by passage over Pt-C in  $\text{H}_2$  at 300—310° into (?)  $\delta$ -methyloctane and *o*- $\text{C}_6\text{H}_4\text{MeEt}$ . The formation of aromatic substances is more pronounced when  $\text{H}_2$  is replaced by  $\text{N}_2$  or  $\text{CO}_2$  whereas less paraffin is produced. Similar observations are recorded with *sec*-butyl- and *iso*amylcyclopentane. The possibilities are discussed that aromatisation is due to preliminary production of a six-membered ring from the side-chain followed by fission of the cyclopentane ring or that aliphatic hydrocarbons are first produced and are transformed into aromatic derivatives. In support of the latter view it is shown that *p*-xylene is formed from diisobutyl, hydrocarbons oxidised to BzOH and *o*- $\text{C}_6\text{H}_4(\text{CO}_2\text{H})_2$  result from *n*-octane, and that *m*-cymene is produced from diisomyl. H. W.

Oxidation of cyclohexane by hydrogen peroxide. G. DUPONT and R. DULOU (Compt. rend., 1936, 203, 92—94).—In  $\text{Et}_2\text{O}$  containing  $\text{OsO}_4$ , cyclohexane is oxidised by  $\text{H}_2\text{O}_2$ , though in anhyd.  $\text{Et}_2\text{O}$  the reaction is slow. MeCHO and AcOH are the principal products. C. R. H.

Contact transformations of allylcyclohexene, cyclohexylallene, and cyclohexylallylene. R. J. LEVINA and D. M. TRACHTENBERG (J. Gen. Chem. Russ., 1936, 6, 764—773).— $\beta\gamma$ -Dibromopropylcyclohexane and quinoline yield allylcyclohexane (I), b.p. 155—156°/755 mm.  $\Delta^1$ -Allylcyclohexene (II) in presence of C-Pt at 200° in  $\text{CO}_2$  yields PhPr and propylcyclohexane, probably by way of  $\Delta^2$ -propenyl- $\Delta^1$ -cyclohexene and propyl- $\Delta^{1,5}$ -cyclohexadiene. (I), under similar conditions, yields  $\Delta^2$ -propenyl- $\Delta^1$ -cyclohexene, which isomerises to (II), and this undergoes further changes as above.  $\gamma$ -cyclohexyl- $\Delta^2$ -propinane isomerises to (I), and this further as above. R. T.

Triple linkings in carbon rings, and the possible structure of the simpler cyclic hydrocarbons of the formula  $\text{C}_n\text{H}_{2n-4}$ . A. E. FAVORSKI [with M. F. SCHOSTAKOVSKI and N. A. DOMININ] (J. Gen. Chem. Russ., 1936, 6, 720—731).—cyclopentanone (I) and  $\text{PCl}_5$  yield a mixture of  $\text{Cl}_2$  and  $\text{Cl}_2$ -derivatives, converted by heating at 40° with 20% KOH in EtOH into chloro- $\Delta^1$ -cyclopentene, b.p. 111—113°, which with Br in  $\text{CHCl}_3$  gives 1-chloro-1:2-dibromocyclopentane, and this yields 1:2-dibromo- $\Delta^1$ -cyclopentene (II), b.p. 78°/5 mm., when warmed with KOH-EtOH. (II), when heated with Na in  $\text{Et}_2\text{O}$ , affords tri(trimethylene)benzene and the di-, tri-, and tetra-merides of  $\Delta^{1,3}$ -cyclopentadiene. Suberone, when treated similarly to (I), yields successively chloro- $\Delta^1$ -cycloheptene, b.p. 58—59°/12 mm., 1-chloro-1:2-dibromocycloheptane, b.p. 105—108°/2 mm., 1-chloro-2-bromo- $\Delta^1$ -cycloheptene, b.p. 80—82°/2 mm.,  $\Delta^{1,2}$ -cycloheptadiene, b.p. 118—119°, tri(pentamethylene)benzene, and unidentified polymerides. R. T.

Rule for substitution in the benzene series. J. C. MCGOWAN (Chem. and Ind., 1936, 607—608).—A substituent, *A*, promotes *o/p*- or *m*-substitution in  $\text{C}_6\text{H}_6$  according to whether the mesomeric effect causes it to resist or assist, respectively, dissociation

of a proton from the compound  $\text{AOH}$ . The following rule expresses this relation. Substitution in the compound  $\text{PhA}$  by cationoid reagents will give largely *o*- and *p*-derivatives if  $K = [\text{AO}^-][\text{H}^+]/[\text{AOH}]$  (measured in dil. aq. solution at room temp.) is  $< 10^{-7}$ , and will give largely the *m*-derivative if  $K$  is  $> 10^{-5}$  g.-mol. per litre.

R. S. C.

Is the methyl group attached to the benzene nucleus positive or negative? W. HUNTENBURG (J. pr. Chem., 1936, [ii], 145, 229—234).—A general discussion of the polarity of  $\text{Me}$  attached to the  $\text{C}_6\text{H}_5$  nucleus and a criticism of the view of Rosenmund (this vol., 105).

H. G. M.

**Constitution and reactivity. XVIII. Condition of the individual positions in the molecule of nitrobenzene.** K. LAUER and R. ODA (J. pr. Chem., 1936, [ii], 146, 61—64).—The nitration of  $\text{PhNO}_2$  by  $\text{KNO}_3$  in 84%, 89%, 95%, and 100%  $\text{H}_2\text{SO}_4$  has been studied. The results are discussed in relation to Hückel's formulation of  $\text{PhNO}_2$ .

H. W.

**Photochemistry of nitro-compounds.**—See this vol., 1178.

**Behaviour of certain aromatic compounds at the anode, in solutions of potassium nitrate.** C. B. MEDINSKI (Acta Univ. Asiae Med., 1933, [vi], No. 6, 3—7).—Nitration in the anode chamber by "nascent"  $\text{HNO}_3$  is applicable only to insol. substances, others being oxidised under these conditions. The velocity of nitration is  $>$  with  $\text{HNO}_3\text{--H}_2\text{SO}_4$ , and that of oxidation  $>$  that of nitration.

R. T.

**Aliphatic substitution and the Walden inversion.** E. D. HUGHES, F. JULIUSBURGER, A. D. SCOTT, B. TOPLEY, and J. WEISS (J.C.S., 1936, 1173—1175).—Since the abs. rate of racemisation of *d*- $\text{CHPhMeBr}$  in  $\text{COMe}_2$  containing  $\text{LiBr}$  agrees, within experimental error, with the abs. velocity of substitution of  $\text{Br}$  for  $\text{Br}$  in  $\alpha$ -phenylethyl bromide, b.p.  $88^\circ/12$  mm., it is concluded that 90% of the mol. act of substitution lead to stereochemical inversion in this reaction.

J. T. A.

**Polymerisation. II. Properties, mechanism of formation, and constitution of di- and polystyrenes.** J. RISI and D. GAUVIN (Canad. J. Res., 1936, 14, B, 255—267; cf. this vol., 196).—The Br-method of McIlhenny (A., 1900, ii, 178) is used to determine the degree of unsaturation of polymerides. Distyrene-I (I), obtained from  $\text{CHPh:CH}\cdot\text{CO}_2\text{H}$  by  $\text{H}_2\text{SO}_4\text{--H}_2\text{O}$  (1 : 1.5) (II) (A., 1883, 475), contains 30% of saturated isomeride (III). The similar product (IV), obtained in 65% yield from  $\text{CHPh:CH}_2$  (V) and (II), contains 50% of (III). The distyrene (VI) of Stocmer and Kootz (A., 1929, 55) is completely saturated. Staudinger's distyrene (VII) (A., 1935, 740) contains only 7% of (III); his tristyrene (VIII) contains 25% of a saturated compound. When further heated with (II), (I) gives more (III) and not an unsaturated isomeride as previously supposed; under these conditions (IV) also gives a little more (III) and (VII) is completely polymerised, but (VIII) is scarcely affected. The polystyrenes obtained from (V) by  $\text{SbCl}_5$  and probably by heat or  $\text{H}_2\text{SO}_4$  are completely saturated. (V) with  $\text{SbCl}_5$  in  $\text{C}_6\text{H}_6$  in the

dark at room temp. gives polystyrenes, m.p.  $60^\circ$  (mol. wt. 636) and  $90\text{--}92^\circ$  (mol. wt. 1335), and by Staudinger's method (*loc. cit.*) gives 10—15% of an unsaturated distyrene and solid polystyrenes, m.p.  $70\text{--}72^\circ$  (mol. wt. 827) and  $53\text{--}55^\circ$  (mol. wt. 566). With  $\text{SnCl}_4$  (I) and (IV) undergo 50% of polymerisation and much cyclisation, but (VI) is unaffected. At  $210\text{--}215^\circ$  (4 days) (I) gives 10% of a polymeride, (VII) gives 50%, and (VIII) 55% thereof; cyclisation does not occur. Hence fission of the di- and trimerides precedes polymerisation, a conclusion confirmed by production of 8% of (VI) from (VIII) at  $210\text{--}215^\circ$ . Mixtures of di- with poly-styrenes and of (III) with (VII) or (VIII) behave at  $210\text{--}215^\circ$  as do the constituents, so that polymerisation is a chain reaction and does not occur in stages. (I) and (IV) are  $\text{CHPh:CH}\cdot\text{CHPhMe}$ , (III) is 1-phenyl-3-methyl-hydrindene, polystyrene is  $\text{CHPh:CH}\cdot[\text{CHPh}\cdot\text{CH}_2]_x\cdot\text{CHPhMe}$ , and polymerisation is stopped by cyclisation of the terminal linking giving  $\text{CHPh}\langle\text{CH}_2\text{C}_6\text{H}_5\rangle\text{CH}\cdot\text{CH}_2\cdot[\text{CHPh}\cdot\text{CH}_2]_x\cdot\text{CHPhMe}$ . The formulae of (VII) and (VIII) are unknown.

R. S. C.

**Organic sulphur compounds. V. New sulphide and its derivatives.** L. BERMEJO and J. J. HERRERA. VI. Preparation and study of  $\alpha$ -phenylpropyl sulphide. L. BERMEJO, J. J. HERRERA and F. M. PANIZO (Anal. Fis. Quím., 1934, 32, 1106—1110, 1182—1186).—V.  $\text{CHPhMeCl}$  with  $\text{K}_2\text{S}$  in  $\text{EtOH}$  yields di- $\alpha$ -phenylethyl sulphide, f.p.  $< 23^\circ$  (sulphoxide, an oil; sulphone, m.p.  $135^\circ$ ), purified through its  $\text{HgCl}_2$  compound (cf. this vol., 1229).

VI.  $\text{CHPhEt}\cdot\text{OH}$  with  $\text{SO}_2\text{Cl}$  gives  $\alpha$ -phenylpropyl chloride, b.p.  $117\text{--}120^\circ/33$  mm., converted as above into the sulphide, b.p.  $190\text{--}192^\circ/12$  mm. (compound with  $2\text{HgCl}_2$ , decomp.  $95^\circ$ ; sulphoxide, m.p.  $45\text{--}46^\circ$ ; sulphone, m.p.  $60^\circ$ ).

F. R. G.

**Azido-derivatives of acetylenic hydrocarbons.** V. A. KUZMIN and S. G. FRIDMAN (Mem. Inst. Chem. Ukrain. Acad. Sci., 1936, 3, 61—76).— $\text{CPh:C}\cdot\text{CPh}_2\text{Cl}$  (I) and  $\text{NaN}_3$  in  $\text{COMe}$ , (20 hr. at the b.p.) yield  $\text{CPh:C}\cdot\text{CPh}_2\text{N}_3$ , m.p.  $165\text{--}170^\circ$  [dibromide, m.p.  $187\text{--}190^\circ$ ; dichloride, m.p.  $180^\circ$  (decomp.)], not decomposed by aq.  $\text{H}_2\text{SO}_4$ . By using  $\text{CPh:C}\cdot\text{CPh}_2\text{Cl}$  in place of (I), an unstable oil, probably containing  $\text{CPh:C}\cdot\text{CMe}_2\text{N}_3$ , is obtained.

R. T.

**Inductive effects in the diphenyl series.**—See this vol., 1183.

**Preparation of 3 : 4-dibromodiphenyl.** F. H. CASE (J. Amer. Chem. Soc., 1936, 58, 1249—1251).—4-Bromo-3-nitrodiphenyl, b.p.  $210\text{--}215^\circ/6$  mm. (from the 4- $\text{NH}_2$ -derivative), is reduced ( $\text{EtOH}\text{--}\text{SnCl}_2\cdot 2\text{H}_2\text{O}$ ) to 4-bromo-3-aminodiphenyl, m.p.  $97\text{--}98^\circ$  [Ac derivative (I), m.p.  $127^\circ$ ], converted (Sandmeyer) into 3 : 4-dibromodiphenyl (II), b.p.  $192\text{--}195^\circ/5$  mm. 2-Bromo-5-nitrodiphenyl, m.p.  $80\text{--}81^\circ$  (from 5 : 2- $\text{NO}_2\text{--C}_6\text{H}_4\text{Br}\cdot\text{N}_2\text{Cl}$ ,  $\text{C}_6\text{H}_6$ , and aq.  $\text{NaOH}$  at  $< 5^\circ$ ), is similarly reduced and then acetylated to 2-bromo-5-acetamidodiphenyl (III), m.p.  $162\text{--}163^\circ$ . The (I) and (II) of Blakey and Scarborough (A., 1928, 165) are (III) and impure 2 : 5-dibromodiphenyl, respectively; the latter with  $\text{Cu}\text{--}\text{Mg}$  alloy followed by  $\text{CO}$ , gives 2-bromodiphenyl-5-carboxylic and diphenyl-

2:5-dicarboxylic acids, whilst oxidation affords 2:5- and only a little 3:4- $C_6H_3Br_2 \cdot CO_2H$ . The product from 3:4- $C_6H_3MeBr \cdot N_2Cl$ ,  $C_6H_6$ , and aq. NaOH is oxidised (aq.  $KMnO_4$ ) to 4-bromodiphenyl-3-carboxylic acid, m.p. 194—195°; 4:3- $C_6H_3MeBr \cdot N_2Cl$  similarly leads to 3-bromodiphenyl-4-carboxylic acid, m.p. 179—180°. H. B.

Action of magnesium on homonuclear dibromodiphenyls. F. H. CASE (J. Amer. Chem. Soc., 1936, 58, 1246—1249).—The amount of  $C_6H_5Ph(MgBr)_2$ , determined by yield (quoted) of  $Ph_2$  on hydrolysis, from Mg (2 atoms) and the following dibromodiphenyls increases in the order 3:5- (I) (26%), 2:5- (II) (39%), and 2:4- (III) (56%); with Cu-Mg alloy the yields are 35.1, 68.8, and 77.9%, respectively. 3:4-Dibromodiphenyl does not react. The  $C_6H_5Ph$  recovered when (II) and (III) are treated with Mg (1 atom) is oxidised to  $o$ - $C_6H_4Br \cdot CO_2H$  showing that the 2-Br is less readily attacked. 2:5- $C_6H_5Ph(MgBr)_2$ , obtained using Cu-Mg, with  $CO_2$ , gives diphenyl-2:5-dicarboxylic acid, m.p. 274—275°; the 3:5-compound affords an impure product. (I) and (II) with 1 atom of Mg followed by  $CO_2$  give 3-bromo-, m.p. 177—178°, and 2-bromo-, m.p. 247—248° (lit. 242—243°), -diphenyl-5-carboxylic acid, respectively. (III), prepared by deamination of its 5- $NH_2$ -derivative, has b.p. 174—176°/7 mm. H. B.

2-Bromo-9-nitrofluorene and 2:2'-dibromo-9:9'-dinitro-9:9'-difluorenyl. C. DALE and R. L. SHRINER (J. Amer. Chem. Soc., 1936, 58, 1502).—The previously described (this vol., 197) normal form (m.p. 170°) of 2-bromo-9-nitrofluorene (I) is 2:2'-dibromo-9:9'-dinitro-9:9'-difluorenyl (II), m.p. 175° (corr.). (II) is obtained in good yield from the K salt of (I) and I (1 mol.) and in small amount when the *aci*-form of (I) is heated with EtOH. H. B.

Discrepant behaviour of anthracenes of different origin towards sulphuryl chloride. M. A. ILJINSKI and B. I. AFREMOV (Ber., 1936, 69, [B], 1824).—An anthracene (I) of 94—96% purity from Kuznezsk (Siberia) was readily and almost quantitatively converted by  $SO_2Cl_2$  in  $CCl_4$  into 9:10-dichloroanthracene, whereas an apparently similar product (II) from Donez (Ukraine) remained unchanged. Reaction occurred readily with (I) and (II) in xylene and (I) and (II) were similarly oxidised to anthraquinone. Purification of (I) and (II) by treatment with superheated steam followed by crystallisation from EtOH and xylene yielded products differing somewhat in appearance and in which the differing behaviour towards  $SO_2Cl_2$  in  $CCl_4$  persisted. H. W.

Hydrogenation of anthracene. E. I. PROKOPETZ and V. N. CHADSHINOV (Chim. Tverd. Topl., 1935, 6, 347—353).—Hydrogenation in presence of  $MoS_3$  at 100—120 atm. is described; 1:2:3:4-tetrahydro-, 1:2:3:4:5:6:7:8-octahydro-, and perhydro-anthracenes are produced, together with a mixture of naphthene hydrocarbons, b.p. 39—150°. CH. ABS. (r)

Synthesis of phenanthrene and hydrophenanthrene derivatives. III. Hydrocarbons of the chrysene, acechrysene, and 3:4-benzphen-

anthrene series; 1:2-benzpyrene derivatives. L. F. FIESER, M. FIESER, and E. B. HERSHBERG (J. Amer. Chem. Soc., 1936, 58, 1463—1468).—3:4-Dihydrophenanthrene-1:2-dicarboxylic anhydride and  $(CH_2 \cdot CH)_2$  in dioxan at 160—180° give 1:2:3:6:15:16-hexahydrochrysene-15:16-dicarboxylic anhydride (I), m.p. 143.5—144°, which when fused with KOH affords hydrochrysenes [containing dihydrochrysene, m.p. 223—226° (when regenerated from the *picrate*, m.p. 142—144°), repeated crystallisation of which from AcOH yields chrysene (II)], which are dehydrogenated (Se at 300—310°) to (II). 4:5-Dimethylchrysene, m.p. 215—215.3°, is similarly obtained from the 4:5- $Me_2$  derivative (this vol., 203) of (I). 3:4-Dihydronaphthalene-1:2-dicarboxylic anhydride and cyclopentadiene and cyclohexadiene at 100° give 1:4-endomethylene-, m.p. 158—159° (decomp. to original components), and 1:4-endoethylene-, m.p. 137—138°, -1:4:9:10:11:12-hexahydrophenanthrene-11:12-dicarboxylic anhydride, respectively, which are reduced ( $H_2$ ,  $PtO_2$ , AcOH) to the 1:2:3:4:9:10:11:12-octahydro-derivatives, m.p. 156—156.5° and 135—135.5°, respectively. KOH-fusion and dehydrogenation of the product from 2:3-dimethyl-1:4:9:10:11:12-hexahydro-5:6-benzphenanthrene-11:12-dicarboxylic anhydride (improved prep.; cf. *loc. cit.*) affords 6:7-dimethyl-3:4-benzphenanthrene, m.p. 94.5—95° (*picrate*, m.p. 143—144°); the parent benzphenanthrene could not be prepared similarly. 1:2:3:4:9:10:11:12-Octahydro-5:6-benzphenanthrene-11:12-dicarboxylic anhydride, m.p. 182—183.2°, is obtained by reduction of the  $H_6$ -derivative (improved prep.; cf. *loc. cit.*). 5:6-Tetramethylene-1:2:3:4-tetrahydro-8:9-acephenanthrene, m.p. 148.6—149°, prepared by reduction [ $H_2$  (3000 lb.),  $PtO_2$ , EtOH, 200°] of its 1-CO-derivative (A., 1933, 67), is completely destroyed on attempted dehydrogenation. Et  $\gamma$ -3-acenaphthylbutyrate,  $Et_2C_2O_4$ , and KOEt give (method: A., 1935, 1495) *Et\_2*  $\alpha$ -oxalyl- $\gamma$ -3-acenaphthylbutyrate, m.p. 83—85°; the crude product is converted by 80%  $H_2SO_4$  at 70—80° into 3:4-dihydro-8:9-acephenanthrene-1:2-dicarboxylic anhydride (III), m.p. 229—232° (previous softening; in quartz) [corresponding *Et\_2* ester, m.p. 140.2—140.6°, formed with some (III) when cyclisation is effected with 82%  $H_2SO_4$ +AcOH], which with  $(CH_2 \cdot CH)_2$  and  $(CH_2 \cdot CMe)_2$  affords 1:2:3:6:15:16-hexahydro-8:9-acechrysene-15:16-dicarboxylic anhydride (IV), m.p. 189—189.3°, and its 4:5- $Me_2$  derivative (V), m.p. 187.5—188°, respectively. KOH-fusion of (V) furnishes a  $H_6$ -derivative, m.p. 193.5—194.5°, of 4:5-dimethyl-8:9-acechrysene, m.p. 222.6—223.1°; (IV) similarly yields a dihydro-8:9-acechrysene, m.p. 153.2—153.5°, attempted dehydrogenation (Se at 300—310°) of which gives an isomeride (?), m.p. 181—182°. Me  $\gamma$ -1-acenaphthylbutyrate and  $Et_2C_2O_4$  lead (as above) to 3:4-dihydro-5:10-aceanthrene-1:2-dicarboxylic anhydride, m.p. 276—277°, whilst Et  $\gamma$ -1-pyrenylbutyrate, m.p. 48.5—49°, similarly affords *Et\_2*  $\alpha$ -oxalyl- $\gamma$ -1-pyrenylbutyrate, m.p. 106—107°, and then (by cyclisation) 1':2'-dihydro-1:2-benzpyrene-3':4'-dicarboxylic anhydride, m.p. 338—340° (decomp.). This is dehydrogenated (S in quinoline) to 1:benzpyrene-3':4'-dicarboxylic anhydride, m.p. 380

382°, which appears to have no carcinogenic activity. All m.p. are corr. H. B.

[Perylene tribromide.] K. BRASS and E. CLAR (Ber., 1936, 69, [B], 1977—1979).—A reply to Zinke et al. (this vol., 1102). H. W.

Reversible oxidisability of organic compounds. *iso*Oxybis-(*p*-bromophenyl)diphenylnaphthacene. L. ENDERLIN (Compt. rend., 1936, 203, 192—194; cf. A., 1930, 1173; 1934, 649).—*o*:11-Di-*p*-bromophenyl-6:12-diphenylnaphthacene 6:11-peroxide, C<sub>42</sub>H<sub>26</sub>O<sub>2</sub>Br<sub>2</sub> (dissociable), with MgI<sub>2</sub> in Et<sub>2</sub>O at room temp. affords the isomeric, non-dissociable, 5:12, 6:11-dioxide, m.p. 258°, which is reduced (Fe or Zn-AcOH) partly to naphthacene, but is unaffected by RMgI. The change probably occurs as a result of a rupture of the O-O linking followed by an allyl change with elimination of MgI<sub>2</sub> to give a structure similar to that of the photo-oxide of anthracene (cf. A., 1935, 1488). J. L. D.

Influence of electric moment on the number of molecules of base fixed by a salt. II. A. ARLOV (Bull. Soc. chim., 1936, [v], 3, 1673—1682; cf. A., 1935, 182, 1448).—The following compounds, prepared by mixing the constituent Co di- and tri-chloroacetates and amines in EtOH solution, are described: [R=(CCl<sub>3</sub>·CO)<sub>2</sub>Co; X=(CHCl<sub>2</sub>·CO)<sub>2</sub>Co]: R<sub>4</sub>NH<sub>4</sub>Ph; R<sub>4</sub>(*o*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); R<sub>4</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); R<sub>4</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); R<sub>4</sub>(*o*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); R<sub>4</sub>(*p*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); R<sub>4</sub>(*o*-OEt·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); R<sub>4</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>); R<sub>4</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>); R<sub>4</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub>); R<sub>4</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub>); R<sub>4</sub>(*p*-C<sub>6</sub>H<sub>4</sub>I·NH<sub>2</sub>); X<sub>5</sub>NH<sub>4</sub>Ph; X<sub>5</sub>2NH<sub>4</sub>Ph; X<sub>2</sub>(*o*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); X<sub>2</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); X<sub>2</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>); X<sub>2</sub>(*o*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); X<sub>2</sub>(*p*-OMe·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); X<sub>2</sub>(*o*-OEt·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); X<sub>2</sub>(*p*-OEt·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>); X<sub>2</sub>(*o*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>); X<sub>2</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>); X<sub>2</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>); X<sub>2</sub>(*m*-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub>); X<sub>2</sub>(*p*-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub>); X<sub>2</sub>(*m*-CN·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub>). The rule found previously relating the dipole moment of the substituent group in NH<sub>2</sub>Ph with the no. of mols. of base co-ordinated by Ni salts holds also for the Co compounds. J. W. S.

Organic molecular compounds. II. III. Compounds of phenols with some synthetic cyclic oxides. G. M. BENNETT and R. L. WAIN (J.C.S., 1936, 1108—1114, 1114—1120; cf. A., 1929, 436).—II. The prep. of the following is described: 3:5-dinitrobenzonitrile (I), m.p. 127°; 5-nitroisophthalyl chloride (II), m.p. 66—68°; 5-nitro-1:3-dicyanobenzene (III), m.p. 205°; trimelic acid trichlorobenzene (IV), m.p. 35—37°, b.p. 213°/13 mm.; *s*-tricyanobenzene (V), m.p. 261—263° (corr.); 5-nitro-1:3-bis-methylthiolbenzene, m.p. 92° [disulphoxide, m.p. 176—185°, presumably a mixture of stereoisomerides; disulphone (VI), m.p. 214°]. Mol. compounds obtained from the following components are described. All are 1:1 compounds except those marked \*, which are 2:1 compounds of the components in the order given. M.p. are given in parentheses. 3:5:1-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·CO<sub>2</sub>Me and  $\alpha$ - (120°) and  $\beta$ - (88—90°) C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub>, benzidine (99—102°), *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub>

(72°), C<sub>10</sub>H<sub>8</sub> (77—80°), acenaphthene (85—87°), phenanthrene (117—119°), *s*-C<sub>6</sub>H<sub>3</sub>(OMe)<sub>3</sub> (71—73°); (I) and  $\alpha$ - (166—169°) and  $\beta$ - (109—113·5°) C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub>, benzidine\* (161—163°), NPhMe<sub>2</sub> (71—73°), NH<sub>2</sub>Ph (87°), *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> (96—98°), C<sub>10</sub>H<sub>8</sub> (123°), acenaphthene (148—150°), phenanthrene (107—108°), fluorene\* (128—130°), Ph<sub>2</sub>\* (96—99°), anthracene\* (151—153°), *s*-C<sub>6</sub>H<sub>3</sub>(OMe)<sub>3</sub> (81—82°), PhMe (41—94°), C<sub>6</sub>H<sub>3</sub>Me<sub>3</sub> (92—97°); 3:5:1-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·COCl and C<sub>10</sub>H<sub>8</sub> (127°), anthracene (130—151°), acenaphthene (149—151°), NPhMe<sub>2</sub>; 3:5:1-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·CO·NH<sub>2</sub> and  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub> (149°), acenaphthene (148—150°); (III) and  $\alpha$ - (147—149°) and  $\beta$ - (105—107·5°) C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub>, benzidine\* (173°), *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> (62°), NH<sub>2</sub>Ph (95—170°), acenaphthene (156—160°); (II) and acenaphthene (139—143°), phenanthrene (134—137°), anthracene (122—154°); (VI) and  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub> (139—172° indef.), NH<sub>2</sub>Ph (126°); (V) and  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub> (165—167°), benzidine [168° (decomp.)]; (IV) and C<sub>10</sub>H<sub>8</sub> (97—101°), acenaphthene (134—137°), phenanthrene (129—131°), anthracene (120—152°), fluorene (75—77°), NPhMe<sub>2</sub> (34—82°). Thermal analysis of the system 2:4:1-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·CN- $\beta$ -C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub> revealed a stable 1:1 compound, congruent m.p. 135°. The function of the polar groups in complex formation is discussed. One of the nuclear C of the NO<sub>2</sub>-compound (or other acceptor mol.) is considered to act as the acceptor in the formation of a link with the other component (donor) (cf. loc. cit.).

III. Some dicarboxylic esters with excess of MgMeI give ditertiary glycols, readily dehydrated by H<sub>2</sub>SO<sub>4</sub>-H<sub>2</sub>O to cyclic oxides. Thus *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>Me)<sub>2</sub> (VII) gives *aaa'*-*α*-tetramethylphthalan (VIII), m.p. 71—72°; Me,  $\beta$ -phenylglutarate gives 4-phenyl-2:6-dimethylheptane-2:6-diol, m.p. 70—71°, dehydrated to 4-phenyl-2:2:6:6-tetramethyltetrahydropyran (IX), m.p. 57·5°; Me<sub>2</sub> phenylsuccinate gives 3-phenyl-2:5-dimethylhexane-2:5-diol, m.p. 61—62°, dehydrated to 3-phenyl-2:2:5:5-tetramethyltetrahydrofuran, m.p. 39—40°; and Me<sub>2</sub> diphenate gives 2:2'-di-( $\alpha$ -hydroxyisopropyl)diphenyl, m.p. 139°, dehydrated to the cyclic oxide (X)  $\begin{matrix} \text{C}_6\text{H}_4\cdot\text{CMe}_2 \\ \text{C}_6\text{H}_4\cdot\text{CMe}_2 \end{matrix} > \text{O}$ , m.p. 90—91·8°. (VII) with

MgMeI-Et<sub>2</sub>O (instead of C<sub>6</sub>H<sub>6</sub>) gives a *hydroxyisopropylphenyl Me ketone*, m.p. 108—111°. These cyclic oxides do not yield compounds with HCl, BF<sub>3</sub>, or HClO<sub>4</sub>, but the thermal diagrams for systems of these oxides and certain phenols showed the formation of mol. compounds (mol. proportions and m.p. in parentheses): (a) (VIII) with  $\alpha$ - (1:1; m.p. 92·6°) and  $\beta$ - (2 oxide:1 naphthol; congruent m.p. 79·3°) C<sub>10</sub>H<sub>7</sub>·OH, *p*-C<sub>6</sub>H<sub>4</sub>Br·OH (1:1; m.p. 54·3°), *p*-C<sub>6</sub>H<sub>4</sub>I·OH (1:1; m.p. 51·8°), *o*- (1:1; m.p. 85·5°) (2 oxide:1 phenol; congruent m.p. 88·5°) and *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, *p*-xylol (1:1; m.p. 40·5°), but not with *s*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>·OH, *s*-C<sub>6</sub>H<sub>4</sub>Br<sub>2</sub>·OH, CH<sub>3</sub>·Ph·CO<sub>2</sub>H, or *o*-C<sub>6</sub>H<sub>4</sub>Me·CO<sub>2</sub>H. (b) (IX) with  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·OH (1:1; m.p. 69°), *o*- (1:1, m.p. 78°) (2 oxide:1 resorcinol; congruent m.p. 67·5°) and *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, but no stable compound with  $\beta$ -C<sub>10</sub>H<sub>7</sub>·OH. (c) (X) with  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·OH [2 oxide:1 naphthol; incongruent m.p. 76° (unstable)], but none with *o*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>. These results support the view that increase in the basicity of O by ring formation and the rigidity of the struc-

tures of the cyclic oxides favour the formation of mol. compounds. The extent of dissociation on melting is estimated in two cases. H. G. M.

**Halogenation of phenolic ethers and anilides.** VII. Method of determining proportions of *o*- and *p*-isomerides in a mixture. B. JONES (J.C.S., 1936, 1231—1234; cf. this vol., 719).—A method suitable for use in nuclear chlorination reactions, depending on the determination of the difference in velocities of substitution of *o*- and *p*-isomerides, is outlined and applied to NHPAc, NHPbZ, and PhSO<sub>2</sub>-NHPh. Controlled addition of Cl<sub>2</sub> (1 mol.) to the anilide yields a mixture of *o*- and *p*-isomerides which is analysed by determining its velocity of further chlorination and observing the coincidence of the velocity with that of an artificial mixture of known composition. F. N. W.

**Mechanism of N-halogenoacylanilide rearrangements.** R. P. BELL (J.C.S., 1936, 1154—1156; cf. A., 1935, 1209).—The rearrangement of NBrPhAc (I) in PhCl catalysed by CCl<sub>3</sub>·CO<sub>2</sub>H involves intramol. migration of halogen only, as no free Br is observed. (I) and HBr react instantly and completely in PhCl to form NHPAc and Br, and under these conditions it is impossible to tell whether formation of *p*-bromoacetanilide is due to migration or nuclear halogenation. F. N. W.

**Alkylthiolacet-anilides, -*p*-toluidides, and the corresponding thionyl compounds.** N. HELLSTROM and T. LAURITZSON (Ber., 1936, 69, [B], 1999—2003).—For identification, the alcohol is converted by PBr<sub>3</sub> into the corresponding bromide, which is heated in EtOH and alkali with *thiolacetanilide*, m.p. 109.5—110°, from SH·CH<sub>2</sub>·CO<sub>2</sub>H and NH<sub>2</sub>Ph in N<sub>2</sub> at 150°, or *thiolacet-p-toluidide*, m.p. 125—126°; the products may then be oxidised by H<sub>2</sub>O<sub>2</sub> to the corresponding sulfoxides. Compounds SR·CH<sub>2</sub>·CO·NHPh are described, the m.p. of the corresponding sulfoxides being placed in parentheses: R=Me, m.p. 77—78° (136—137°); Et, m.p. 58—59° (160—161°); Pr<sup>a</sup>, m.p. 55.5—56° (137.5—138°); Pr<sup>β</sup>, m.p. 66.5—67° (157—158°); Bu<sup>a</sup>, an oil (m.p. 143.5—144°); *sec*.-Bu, an oil (127—128°); Bu<sup>β</sup>, m.p. 45—46° (145—146°). The analogous substances SR·CH<sub>2</sub>·CO·NH·C<sub>6</sub>H<sub>4</sub>Me-*p*, have been prepared: R=Me, m.p. 102—103° (173—174°); Et, m.p. 81—82° (174—175°); Pr<sup>a</sup>, m.p. 78—79° (147—148°); Pr<sup>β</sup>, m.p. 65—66° (148—149°); Bu<sup>a</sup>, m.p. 61—62° (146—147°); *sec*.-Bu, m.p. 56—57° (145—146°); Bu<sup>β</sup>, m.p. 85—86° (141—142°). (Cf. this vol., 1231.) H. W.

**M.p. curve of *o*-anisidine and *o*-chloroaniline mixtures.** S. AOYAMA and I. MORITA (J. Pharm. Soc. Japan, 1933, 53, 1089—1093).—Pure *o*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub> has a double m.p.,  $\alpha$ -form, m.p. —11.92°, and  $\beta$ -form, m.p. —1.78°. The m.p. curve for mixtures with pure *o*-anisidine (I), b.p. 90—91°/4 mm., is given; there are two eutectics, m.p. —16.8° [25% of (I)] and —13.0° [68.63% of (I)].

CH. ABS. (r)

**Absorption [spectra] of anils of aliphatic ketones.** (MME.) P. RAMART-LUCAS and (MLLE.) M. MONTAGNE (Bull. Soc. chim., 1936, [v], 3, 916—

918).—The ultra-violet absorption spectra of the anil (I) of COEt<sub>2</sub>, of its isomeride,  $\gamma$ -anilino- $\Delta^2$ -pentene (II), of  $\gamma$ -anilinopentane and its Ac derivative, and of  $\gamma$ -(*N*-phenylacetamido)- $\Delta^2$ -pentene have been determined in hexane or EtOH. No conclusions can be reached concerning the existence in hexane solutions of (I) of its tautomeride (II).

H. G. M.

**Absorption in the ultra-violet and structure of anils and  $\alpha$ -ethylenic amines.** (MME.) P. RAMART-LUCAS and M. J. HOCH (Bull. Soc. chim., 1936, [v], 3, 918—929; cf. preceding abstract).—The prep. of the following is described (cf. A., 1935, 336): *Ph Bu<sup>a</sup> ketone-anil*, b.p. 160—161°/15 mm., and *p-methoxyanil*, m.p. 61°, b.p. 196—198°/15 mm., *Ph  $\alpha$ -dimethylamyl ketone-anil*, b.p. 200—202°/25 mm., and *p-methoxyanil*, b.p. 221—222°/17 mm., *Ph phenyltert-butyl ketone-anil*, b.p. 229—230°/23 mm., *cis*-, m.p. 86° (cf. lit.), and *trans*-, m.p. 105°, *-deoxybenzoinanil*. The absorption spectra of the foregoing imines and of the following have been determined: the anils derived from COMeEt, COEt, COPhEt, COPhMe, COPr<sup>a</sup>, COPh<sub>2</sub>, PhCHO, Me nonyl ketone, cyclohexanone, and 3-methylcyclohexanone: the *o*-, *m*-, and *p*-methyl- and *o*- and *p*-methoxy-anils from COPr<sup>a</sup>; the *p*-methylanils from COPh<sub>2</sub> and Me nonyl ketone; the *p*-methoxyanils from COPhMe and PhCHO; NMePh·CET·CHPr<sup>a</sup>, NMePh·CPh·CH<sub>2</sub>, NEtPh·CPh·CH<sub>2</sub>, NMePh·CH·CHPh, NMePh·CPh·CHPh, and 1-methylanilino- $\Delta^1$ -cyclohexene. The spectra do not permit the detection of the tautomeride NHR·CR'·CR''R''' in solutions of NR·CR'·CHR'R''' (cf. A., 1934, 1336). The spectra of the trialkylacetophenones and diaryl ketones present anomalies attributed to deformation of the valency angles of >C=N-. H. G. M.

**Nitroamines. VI. 3:6-Dinitrophenylnitroamine.** E. MACCIOTTA (Rend. Semin. Fac. Sci. R. Univ. Cagliari, 1934, 4, 143—144; Chem. Zentr., 1935, ii, 3647; cf. A., 1933, 387).—Treatment of 3:6-dinitroaniline with HNO<sub>3</sub>, followed by Ac<sub>2</sub>O, yields 3:6-dinitrophenylnitroamine, isolated as Ag salt. H. N. R.

**Alkaline fusion. I. Fusion of potassium sulphanilate.** N. N. VOROSHOV and M. M. SCHEMJAKIN (J. Gen. Chem. Russ., 1936, 6, 880—883).—K sulphanilate and KOH (1:10 mol.) at 350—355° (45 min.) yield almost exclusively *p*-OH·C<sub>6</sub>H<sub>4</sub>·SO<sub>3</sub>H (77% yield). R. T.

**N-Methylanilides.** J. RODRÍGUEZ VELASCO (Anal. Fís. Quím., 1934, 32, 807—814).—NPhMeAc with NaOEt yields NHPHMe and PrCO<sub>2</sub>H, indicating the intermediate formation of NPhMe·COPr. The behaviour of NPhMeAc with MgCl·CH<sub>2</sub>Ph is in agreement with Maxim (A., 1926, 837), and that of NPhMe·CO·CH·CHPh with MgPhBr concordant with Maxim *et al.* (A., 1928, 1004). F. R. G.

**Positive reaction of glass on *o*-tolidine.** D. W. HORN (Amer. J. Pharm., 1936, 108, 324—325).—*o*-Tolidine gives a yellow colour, as does Cl<sub>2</sub>, in contact with glass, but not when the glass is washed with dil. HCl. When bottles which do not give the

test are heated with  $H_2O$  under pressure they become active.

J. L. D.

**Stereoisomerism due to restricted rotation about a single bond.** II. 8-Nitro-*N*-benzenesulphonyl-1-naphthylglycine and analogous compounds. H. C. TUAN, T. T. HSU, and E. I. F. HSÜ (J. Chinese Chem. Soc., 1936, 4, 131—141).—The rate of racemisation of 1-8-nitro-*N*-benzenesulphonyl-1-naphthylglycine in EtOH, NaOH, and AcOH has been determined. 6-Nitro-*N*-benzenesulphonyl-2:4-dimethylaniline and  $CH_2Br \cdot CO_2Et$  give *Et* 6-nitro-*N*-benzenesulphonyl-2:4-dimethylanilinoacetate, m.p. 93—95°, hydrolysed to *N*-benzenesulphonyl-6-nitro-2:4-dimethylphenylglycine, m.p. 212°, the cinchonine salt, m.p. 218° (decomp.), of which shows no mutarotation. 6-Bromo-*N*-benzenesulphonyl-2:4-dimethylaniline, m.p. 155—156°, and  $CH_2Br \cdot CO_2Et$  afford 6-bromo-*N*-benzenesulphonyl-2:4-dimethylphenylglycine, m.p. 196—197°, which does not form crystalline salts. 2:4:6-Tribromo-3-acetamidohydrocinnamic acid, decomp. 267°, gives a quinine salt, m.p. 180—183°, which does not show mutarotation. It is concluded that Br, Me, and  $NO_2$  are not large enough to cause restricted rotation in this type of compound.

F. R. S.

**Manufacture of substituted aminochrysenes.**—See B., 1936, 874.

**Diacetyl derivative of 2:6-tolylenediamine.** E. ROSTOV'TZEVA (J. Appl. Chem. Russ., 1936, 9, 1116).—*NN'*-Diacetyl-2:6-tolylenediamine melts at 310—311°, and not, as stated by Green and Lawson (J.C.S., 1891, 59, 1017), at 202°.

R. T.

**Preparation of certain 2:3-naphthalene derivatives.** H. H. HODGSON and R. L. ELLIOTT (J.C.S., 1936, 1151—1154).—Nitration of 2-iodo-*NN'*-diacetyl-1:4-naphthylenediamine (I) gives the corresponding 2- $NO_2$ -derivative (II), m.p. 309° (lit. 295°), which when refluxed with  $H_2SO_4$ -EtOH- $H_2O$  gives 2-nitro-1:4-naphthylenediamine, m.p. 241°. The ease of displacement of halogen in the 2-halogen compounds corresponding with (I) by  $NO_2$  is in the order  $I > Cl > Br$ , whilst prolonged reaction gives 2:3-dinitro-*NN'*-diacetyl-1:4-naphthylenediamine (III), m.p. above 360°, hydrolysed by  $H_2SO_4$ -EtOH to the free diamine, m.p. 207°. Reduction of (II) and (III) by  $SnCl_2$ -HCl-EtOH gives the stannichlorides of the corresponding 2- $NH_2$ - and 2:3-( $NH_2$ )<sub>2</sub>-compounds. (III) when boiled with 20% aq. NaOH gives 2:3-dinitro-1:4-dihydroxynaphthalene, m.p. 357°, methylated to the corresponding 1:4-(*OMe*)<sub>2</sub>-compound, m.p. 190°. Nitration of 4-chloro- and of 4-bromo-*NN'*-diacetyl-1:2-naphthylenediamine gives the corresponding 4-chloro-3-nitro-, m.p. 208° (oxidised by alkaline  $KMnO_4$  to phthalic acid), and 4-bromo-3-nitro-, m.p. 195°, compounds, respectively, whilst nitration of the 4-I-analogue gives 4-nitro-*NN'*-diacetyl-1:2-naphthylenediamine, m.p. 124°. 3-Chloro-aceto-1-naphthalide with diacetylorthonitric acid or conc.  $HNO_3$  yields 3-chloro-2-nitroaceto-1-naphthalide, m.p. 225°, hydrolysed by  $H_2SO_4$ -EtOH- $H_2O$  to the amine (IV), m.p. 149°. Nitration above 30° gives 2:3-dinitroaceto-1-naphthalide, m.p. 275.5°. 3-Bromo-2:3-dinitroaceto-1-naphthalide, m.p. 235°, and 3-iodo-

(VI), m.p. 250° (Ac derivative, m.p. 298°), 2-nitro-1-naphthylamine were similarly prepared. (IV), (V), and (VI) when diazotised below 20° and then boiled with EtOH give, respectively, 3-chloro-2-nitronaphthalene, m.p. 79°, and the corresponding 3-Br-, m.p. 84° (lit. 82—83°), and 3-I-, m.p. 105° (lit. 89—89.5°), compounds. Diazotisation above 20° leads to the formation of complex azo-products, m.p. 145° from (IV), and m.p. 165° from (VI).

H. G. M.

**Magenta series.** II. Higher basic members. J. T. SCANLAN (J. Amer. Chem. Soc., 1936, 58, 1427—1429; cf. A., 1935, 973).—4:4'-Diamino-3:5:3':3''-tetramethyl-, -3:5:3':5':3''-penta-methyl-, and -3:5:3':5':3''-hexamethyl-fuchsonimonium chlorides [magenta IV, V, and VI, respectively; termed below (IV), (V), and (VI), respectively] are identified by absorption spectra and analysis of their carbinol bases. The data obtained (below) confirm the view (*loc. cit.*) that the " $CH_2O$  process" for the prep. of magenta involves fission of the diaminodiphenylmethane. (IV) is prepared (details: *loc. cit.*) from 4:4'-diamino-3:5:3':5'-tetramethyldiphenylmethane (I) [from *m*-2-xylylene hydrochloride (II) and 40%  $CH_2O$  in dil. HCl at 70—75°], *o*- $C_6H_4Me \cdot NH_2$ , *o*- $C_6H_4Me \cdot NH_2 \cdot HCl$ , *o*- $C_6H_4Me \cdot NO_2$ , and  $FeCl_2 \cdot 4H_2O$ . (V) is obtained from 4:4'-diamino-3:3'-dimethyldiphenylmethane, *m*-2-xylylene (III), (II), nitro-*m*-xylene (or *o*- $C_6H_4Me \cdot NO_2$ ), and  $FeCl_2 \cdot 4H_2O$  or from (II), (III), *m*-4-xylylene, nitro-*m*-xylene, and  $FeCl_2 \cdot 4H_2O$ . (VI) is prepared from (I), (II), (III), *o*- $C_6H_4Me \cdot NO_2$ , and  $FeCl_2 \cdot 4H_2O$ .

H. B.

**Azoformamides.** II. Action of hydrochloric and hydrobromic acids on naphthaleneazoformamides. R. JUSTONI (Gazzetta, 1936, 66, 375—379).— $\beta$ - $C_{10}H_7 \cdot N_2 \cdot CO \cdot NH_2$  and conc. HCl yield 1-chloro- $\beta$ -naphthylsemicarbazide, m.p. 168.5° (decomp.), also obtained from 1:2- $C_{10}H_6Cl \cdot NH_2$  by way of 1-chloro- $\beta$ -naphthylhydrazine hydrochloride. Action of conc. HBr similarly gives 1-bromo- $\beta$ -naphthylsemicarbazide, m.p. 158° (decomp.). These compounds are oxidised by  $HNO_2$  to 1-chloro-, m.p. 190—191° (decomp.), and 1-bromo- $\beta$ -naphthaleneazoformamide, m.p. 197—198° (decomp.). Action of HBr on the last yields 1:6-dibromo- $\beta$ -naphthylsemicarbazide, m.p. 173—174° (also obtained from 1:6:2- $C_{10}H_5Br_2 \cdot NH_2$ ), and thence 1:6-dibromo- $\beta$ -naphthaleneazoformamide, m.p. 212° (decomp.).

E. W. W.

**Azo-compounds of fuchsin.** G. ODDO, M. RUSSO, and A. RODRIGUEZ (Gazzetta, 1936, 66, 405—409).—Completely diazotised fuchsin couples with PhOH to give 4:4':4''-tri-*p*-hydroxybenzeneazo-3-methyltriphenylmethane, m.p. 180°, of which the  $Ac_3$  derivative, decomp. 90°, is oxidised to the  $Ac_3$  derivative, decomp. 110—120°, of 4:4':4''-tri-*p*-hydroxybenzeneazo-3-methyltriphenylcarbinol, decomp. 160°. With  $NPhMe_2$ , (I) yields 4:4':4''-tri-*p*-dimethylaminobenzeneazo-3-methyltriphenylmethane, decomp. 145°, m.p. 258° (monohydrochloride), which gives the corresponding carbinol, decomp. 140°, m.p. 260° (Ac derivative, decomp. 132°, m.p. 150°).

E. W. W.

**Reaction of selenium dioxide with arylhydrazines.** J. J. POSTOVSKI, B. P. LUGOVKIN, and

G. T. MANDRIK (Ber., 1936, 69, [B], 1913—1916).—The action of  $\text{SeO}_2$  on aq. solutions of the hydrochlorides of  $\text{NHPh}\cdot\text{NH}_2$ , *p*-bromo- and *m*-nitrophenylhydrazine, and 1- and 2-naphthylhydrazine gives Se and the corresponding diazonium chloride.  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}_2\cdot\text{HCl}$  gives  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}\cdot\text{N}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2\cdot p'$  and  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_3$ .  $\text{NPh}_2\cdot\text{NH}_2$  affords  $\text{NHPh}_2$  and  $\text{N}_2$ .

**Aromatic nitro-derivatives. VIII. 1-Bromo-3:4-dinitrobenzene.** A. MANGINI (Gazzetta, 1936, 66, 343—350).—1:3:4- $\text{C}_6\text{H}_3\text{Br}(\text{NO}_2)_2$  (I) with  $\text{NH}_3$  gives *o*-bromo-2-nitroaniline (Ac derivative, new m.p. 140—141°; Bz derivative, m.p. 122—123°), and with  $\text{N}_2\text{H}_4$ , 5-bromo-2-nitrophenylhydrazine (II), m.p. 159.5—160° (Ac, m.p. 205—206°, and Bz, m.p. 197.5—198.5°, derivatives), which can be converted into  $p\text{-C}_6\text{H}_4\text{Br}\cdot\text{NO}_2$ . (II) with  $\text{PhNCS}$  furnishes 4-phenyl-1-(5'-bromo-2'-nitrophenyl)isothiosemicarbazide, m.p. 186.5—187.5°; with  $p\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{COMe}$ , *p*-aminoacetophenone-5-bromo-2-nitrophenylhydrazone, m.p. 195.5—196.5°; and with  $\text{ClCO}_2\text{Et}$ , Et *o*-bromo-2-nitrophenylhydrazoformate, m.p. 130—131°, converted by  $\text{NH}_3\text{-EtOH}$  into 1-(5'-bromo-2'-nitrophenyl)semicarbazide, m.p. 233—234° (decomp.), also obtained from (I). Action of  $\text{NH}_2\cdot\text{NH}\cdot\text{CO}\cdot\text{NHPh}$  on (I) or of  $\text{PhNCO}$  on (II) yields 4-phenyl-1-(5'-bromo-2'-nitrophenyl)semicarbazide, m.p. 236—237°. E. W. W.

**Interaction of arylsulphonylphenylhydrazines with bromine.** F. BELL (J.C.S., 1936, 1242—1244). *p*-Toluenesulphonylphenylhydrazine (I) with Br in  $\text{CHCl}_3$  gives 4-bromophenylhydrazine *p*-toluenesulphonate, m.p. 212°, and *p*-toluenesulphonyl-2:4-dibromophenylhydrazine, m.p. 166°, which with Br in  $\text{C}_5\text{H}_5\text{N}$  yields 2:4-dibromobenzenediazonium *p*-toluenesulphonate, m.p. 128°. Benzenesulphonyl-2:4-dibromoanilide, m.p. 128°, is obtained by bromination of the 4-Br compound. (I) and Br in  $\text{C}_5\text{H}_5\text{N}$  for a short time yield benzenediazonium *p*-toluenesulphonate, decomp. 93°, and after 2 days, form di-*p*-toluenesulphonylphenylhydrazine, m.p. 194°. 4-Bromophenylhydrazine (II) and  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_2\text{Cl}$  give *p*-toluenesulphonyl-4-bromophenylhydrazine, m.p. 144°, brominated to 4-bromobenzenediazonium *p*-toluenesulphonate, decomp. 124°. Benzenesulphonylphenylhydrazine and Br in  $\text{CHCl}_3$  afford benzenesulphonyl-2:4-dibromophenylhydrazine, m.p. 177°, converted by Br in  $\text{C}_5\text{H}_5\text{N}$  into 2:4-dibromobenzenediazonium sulphinate, decomp. 98°. (II) and  $\text{PhSO}_2\text{Cl}$  yield benzenesulphonyl-4-bromophenylhydrazine, m.p. 140°, converted by Br in  $\text{C}_5\text{H}_5\text{N}$  into 4-bromobenzenediazonium benzenesulphonate. F. R. S.

**Inversion of isodiazotates into normal diazotates.** A. BRIVEC (Gazzetta, 1936, 66, 374).—This reaction (cf. this vol., 328—329) can be brought about by action of  $\text{CO}_2$  in the absence of light. E. W. W.

**Direct benzylation of monohydric phenols with benzyl chloride in presence of phosphorus pentoxide.** K. A. ANDRIANOV (J. Gen. Chem. Russ., 1936, 6, 846—851).— $\text{PhOH}$ ,  $\text{CH}_3\text{PhCl}$ , and  $\text{P}_2\text{O}_5$  in  $\text{PhMe}$  (130—135°; 8 hr.) yield *o*- and *p*-benzyl and dibenzyl-phenol. Under similar conditions *o*-cresol affords 6-benzyl- and 4:6-dibenzyl-*o*-cresol, *m*-cresol gives benzyl-, m.p. 95°, and dibenzyl-*m*-cresol,

m.p. 130—134°, and *p*-cresol yields benzyl-, b.p. 206—208°/17 mm., and dibenzyl-*p*-cresol, b.p. 250—260°/30 mm. R. T.

**Pyrolysis of chlorophenols.** F. BELL (J.C.S., 1936, 1244).—Pyrolysis of  $o\text{-C}_6\text{H}_4\text{Cl}\cdot\text{OH}$  gives some diphenylene dioxide (*d*-nitro-derivative, m.p. 257°), whilst  $p\text{-C}_6\text{H}_4\text{Cl}\cdot\text{OH}$  gives some 3:6-dichlorodiphenylene oxide and a phenolic substance, m.p. 83°, together with other unidentified phenolic substances.

H. G. M.

**Nitration of phenols in chloroform.** E. BARONI and W. KLEINAU (Monatsh., 1936, 68, 251—260).— $\text{HNO}_3$  (*d* 1.4) is added to phenols in  $\text{CHCl}_3$  at 20°, the following being obtained in the yields stated: *o*- (26%) and  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$  (61%); 3:5-dinitro-*o*-cresol (88%); 4- (25%) and 6-nitro-*m*-cresol (43%); 3:5-dinitro-*p*-cresol (87%); 4:6-dinitro-2- (93%) and 2:6-dinitro-4-cyclohexylphenol (94%); 5-nitrosalicylic acid (99%); 3-nitro-4-hydroxybenzoic acid (75%) (with some 2:4-dinitrophenol); 2:4-dinitro- $\alpha$ -naphthol (yield variable). R. S. C.

**Preparation of thymol from *m*-cresol. III. Properties of the mixture of *m*-cresol and thymol.** K. ONO and M. IMOTO (J. Soc. Chem. Ind. Japan, 1936, 39, 215b).—The m.p. of mixtures of *m*-tolyl- and thym-oxyacetic acid (which form a eutectic at 91° with 25.7% of the latter), and  $d^4$  of mixtures of *m*-cresol and thymol, are expressed graphically. E. W. W.

**Rearrangement of phenyl allyl ethers. [I. Phenyl pentenyl ethers.]** W. M. LAUER and W. F. FILBERT. II. Phenyl crotyl ether. W. M. LAUER and H. E. UNGNADE (J. Amer. Chem. Soc., 1936, 58, 1388—1392, 1392—1393).—I. Repeated saturation of  $\text{CH}_2\text{CH}\cdot\text{CH}\cdot\text{Et}\cdot\text{OH}$  with dry  $\text{HCl}$  at 0° gives approx. equal amounts of  $\gamma$ -chloro- $\Delta^a$ -pentene, b.p. 50—50.2°/150 mm., and  $\alpha$ -chloro- $\Delta^b$ -pentene (I), b.p. 62—63.2°/146—149 mm., which with  $\text{PhOH}$  and anhyd.  $\text{K}_2\text{CO}_3$  in  $\text{COMe}_2$  afford Ph  $\alpha$ -ethylallyl (II), b.p. 92—93°/15 mm. [with (III)], and Ph  $\Delta^b$ -pentenyl ether (III), b.p. 118.6°/20 mm., respectively. (II) and (III) are oxidised ( $\text{KMnO}_4$ , aq.  $\text{COMe}_2$ ) to  $\text{OPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  and  $\text{OPh}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ , respectively. (II) heated in  $\text{NPhEt}_2$  rearranges to the expected *o*- $\Delta^b$ -pentenylphenol, b.p. 131—132.5°/16 mm. [phenylcarbamate, m.p. 67—68°; Me ether, b.p. 143—145°/35 mm. (ozonolysis product,  $\text{EtCHO}$ )], also obtained from  $\text{NaOPh}$  and (I) in  $\text{C}_6\text{H}_6$ . (III) similarly rearranges unexpectedly to *o*- $\alpha$ -methyl- $\Delta^b$ -butenylphenol (IV), b.p. 125—127°/16 mm. (phenylcarbamate, m.p. 108.5—109.5°), also formed by rearrangement of Ph  $\alpha$ -methyl- $\Delta^b$ -butenyl ether (Claisen *et al.*, A., 1925, i, 656) [which is oxidised ( $\text{KMnO}_4$ , aq.  $\text{COMe}_2$ ) to  $\text{OPh}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$ ]. Ozonolysis of the Me ether, b.p. 135—136°/35 mm., of (IV) gives  $\text{CH}_2\text{O}$ ,  $\text{MeCHO}$ , and  $\alpha$ -*o*-anisylpropaldehyde (?) (semicarbazone, m.p. 162.2—162.6°; 2:4-dinitrophenylhydrazone, m.p. 123—125°; corresponding acid, m.p. 100—101°). *o*- $\alpha$ -Methyl- $\Delta^b$ -butenylphenoxyacetic acid, m.p. 128—130°, is oxidised ( $\text{KMnO}_4$ , aq.  $\text{COMe}_2$ ) to  $\alpha$ -*o*-carboxymethoxyphenylpropionic acid (V), m.p. 170—171°. *o*- $\Delta^b$ -Pentenylphenoxyacetic acid has m.p. 108.5—110°.

II. *o*- $\alpha$ -Methylallylphenol (Claisen and Tietze, A.,

1926, 1241), obtained by rearrangement of  $\text{CHMe}:\text{CH}:\text{CH}_2\cdot\text{OPh}$  [oxidised ( $\text{KMnO}_4$ , aq.  $\text{COMe}_2$ ) to  $\text{OPh}:\text{CH}_2\cdot\text{CO}_2\text{H}$ ], with  $\text{CH}_2\text{Cl}:\text{CO}_2\text{H}$  and aq.  $\text{NaOH}$  gives *o*- $\alpha$ -methylallylphenoxycetic acid, m.p. 120—120.5°, which is oxidised to (V) (above). This result supports the constitution assigned to (IV) (above).

H. B.

**Identification of phenolic ethers as picrates.** O. L. BARIL and G. A. MEGRIDICHIAN (J. Amer. Chem. Soc., 1936, 58, 1415—1416).—The ether (1 mol.) is treated with picric acid (1.05 mols.) in  $\text{CHCl}_3$  and the (1 : 1) picrate recrystallised from  $\text{CHCl}_3$  (hydrolysis often occurs with  $\text{EtOH}$ ). The picrates of the following are new:  $\text{PhOMe}$ , m.p. 79—81°;  $(\text{CH}_2\text{Ph})_2\text{O}$ , m.p. 77—78°;  $\text{CH}_2\text{Ph}:\text{OMe}$ , m.p. 115—116°;  $\text{PhOBu}^t$ , m.p. 110—112°; *o*- $\text{C}_6\text{H}_4(\text{OEt})_2$ , m.p. 69—71°; *o*-, m.p. 118—119.5°, *m*-, m.p. 113—114°, and *p*-, m.p. 88—89°; *o*- $\text{C}_6\text{H}_4\text{Me}:\text{OMe}$ ; *o*-, m.p. 117.5—118.5°, *m*-, m.p. 114—115°, and *p*-, m.p. 110—111°; *o*- $\text{C}_6\text{H}_4\text{Me}:\text{OEt}$ ; eugenol, m.p. 62—63°; eugenol Me ether, m.p. 114—115°; isoeugenol, m.p. 46—47.5°; *p*- $\text{OH}:\text{C}_6\text{H}_4\text{OMe}$ , m.p. 43—44°; *p*- $\text{C}_6\text{H}_4(\text{OMe})_2$ , m.p. 47—48°;  $\alpha$ -, m.p. 127—127.5°, and  $\beta$ -, m.p. 113—113.5°;  $\text{C}_{10}\text{H}_7\text{OMe}$ ;  $\alpha$ -, m.p. 107—108°, and  $\beta$ -, m.p. 99—100.5°;  $\text{C}_{10}\text{H}_7\text{OEt}$ ; *p*- $\text{NO}_2\text{C}_6\text{H}_4\text{OCH}_2\text{Ph}$ , m.p. 84—84.5°;  $\text{PhOEt}$ , m.p. 91—92°;  $\text{Ph}_2\text{O}$ , m.p. 108—110°; 1 : 2 : 3- $\text{C}_6\text{H}_3(\text{OMe})_3$ , m.p. 78.5—80°; *m*- $\text{OH}:\text{C}_6\text{H}_4\text{OMe}$ , m.p. 68—69.5°; *m*- $\text{OH}:\text{C}_6\text{H}_4\text{OEt}$ , m.p. 105—106°; *m*- $\text{C}_6\text{H}_4(\text{OMe})_2$ , m.p. 56—58°; *m*- $\text{C}_6\text{H}_4(\text{OEt})_2$ , m.p. 108—109°; safrole, m.p. 104—105.5°; isosafrole, m.p. 74—75°;  $\text{CPh}_3\text{OMe}$ , m.p. 56—57.5°. Some of the picrates are unstable in air.

H. B.

***o*-Phenylene sulphate or sulphurylpyrocatechol.** L. DENIVELLE (Compt. rend., 1936, 203, 194—196).— $\text{SO}_2\text{Cl}_2$  with the  $\text{Na}_1$ -derivative of pyrocatechol in dry  $\text{C}_6\text{H}_6$  at 0° affords a chloropyrocatechol (cf. A., 1894, i, 368; 1911, i, 729) and *o*-hydroxyphenyl chlorosulphonate (not purified), which is easily hydrolysed, and with hot  $\text{C}_5\text{H}_5\text{N}$  affords *o*-phenylene sulphate (I), m.p. 47° (cf. A., 1926, 1244). Thionylpyrocatechol (A., 1927, 354) cannot be oxidised to (I).

J. L. D.

***C*-Alkylresorcinols. II. Synthesis of polyalkylresorcinols.** R. C. SHAH and P. R. MEHTA (J. Indian Chem. Soc., 1936, 13, 358—367).—4 : 6-Diethylresorcinol (A., 1929, 821) in dry  $\text{Et}_2\text{O}$  containing  $\text{HCl}$  (gas) with  $\text{Zn}(\text{CN})_2$  affords a ketimine hydrochloride, decomposed by hot  $\text{H}_2\text{O}$  to give 2 : 6-dihydroxy-3 : 5-diethylbenzaldehyde (I), m.p. 68—70° (*p*-nitrophenylhydrazone, m.p. 217—219°), which with  $\text{CH}_2(\text{CO}_2\text{Et})_2$  and piperidine at room temp. affords *Et* 5-hydroxy-6 : 8-diethylcoumarin-3-carboxylate, m.p. 155—157°, and with dry  $\text{HCl}$  (gas) and 5 : 6-dimethoxy-1-hydrindone (II) in dry  $\text{EtOAc}$  is converted into 5-hydroxy-5' : 6'-dimethoxy-6 : 8-diethyl-2 : 3(3' : 2')-indenobenzopyrylium chloride, m.p. 209—210° (perchlorate, m.p. 155—158°). (I) with  $\text{Zn-Hg}$  in dil.  $\text{HCl}$  at 100° affords 2-methyl-4 : 6-diethylresorcinol, m.p. 51—53° (*di-p*-nitrobenzoyl derivative, m.p. 161—162°). Reduction ( $\text{Zn-Hg}$ ;  $\text{HCl}$ ) of orsacetophenone ( $\text{Bz}_2$  derivative, m.p. 97—98°) affords 5-methyl-4-ethylresorcinol (III) ( $\text{Hg}$  derivative; *di-p*-nitrobenzoyl derivative, m.p. 173—174°), converted through the ketimine into 4 : 6-dihydroxy-2-methyl-3-ethylbenzaldehyde (IV), m.p. 161—162° (*p*-nitrophenylhydrazone, m.p. 255—257°), the structure of which is proved by its conversion by  $\text{CH}_2(\text{CO}_2\text{Et})_2$  and piperidine into *Et* 7-hydroxy-5-methyl-6-ethylcoumarin-3-carboxylate, m.p. 165—167°, which exhibits a strong fluorescence in conc.  $\text{H}_2\text{SO}_4$ . (IV) with (II) in dry  $\text{EtOAc}$  containing dry  $\text{HCl}$  affords 7-hydroxy-5' : 6'-dimethoxy-5-methyl-6-ethyl-2 : 3(3' : 2')-indenobenzopyrylium chloride, m.p. >300° (perchlorate, m.p. >315°). (IV) with  $\text{CH}_2\text{Ac}:\text{CO}_2\text{Et}$  containing piperidine at room temp. gives a product which with dil.  $\text{HCl}$  affords a pyrylium salt,  $\text{C}_{24}\text{H}_{25}\text{O}_5\text{Cl}$ , m.p. 295—298°, probably as a result of the condensation of the 3-acetylcoumarin first formed with a second mol. of (IV). (III) with malic acid in 85%  $\text{H}_2\text{SO}_4$  affords 7-hydroxy-5-methyl-6-ethylcoumarin, m.p. 211—212°, and with  $\text{CH}_2\text{Ac}:\text{CO}_2\text{Et}$  in 85%  $\text{H}_2\text{SO}_4$  it gives 5-hydroxy-4 : 7-dimethyl-6-ethylcoumarin, m.p. 187—189°. (III) with  $\text{Zn-Hg}$  and dil.  $\text{HCl}$  at 100° affords 5 : 6-dimethyl-4-ethylresorcinol, m.p. 145—146° (*di-p*-nitrobenzoyl derivative, m.p. 224—225°), and by the Hoesch reaction gives 2 : 4-dihydroxy-6-methyl-5-ethylacetophenone (V), m.p. 107—108° ( $\text{Bz}_2$  derivative, m.p. 61—63°; phenylhydrazone, m.p. 197—198°; ketimine hydrochloride, m.p. 237—238°), which with  $\text{Zn-Hg}$  in dil.  $\text{HCl}$  at 100° gives 5-methyl-4 : 6-diethylresorcinol (VI), m.p. 80° (*di-p*-nitrobenzoyl, m.p. 243—245°, and  $\text{Ac}_2$ , m.p. 69—70°, derivatives), converted as above into 2 : 6-dihydroxy-4-methyl-3 : 5-diethylbenzaldehyde (VII), m.p. 117—118° (*p*-nitrophenylhydrazone, m.p. 224—225°), which with  $\text{CH}_2(\text{CO}_2\text{Et})_2$  and piperidine gives *Et* 5-hydroxy-7-methyl-6 : 8-diethylcoumarin-3-carboxylate, m.p. 181—183°, thus confirming the structure of (V). (VII) with (II) in dry  $\text{EtOAc}$  containing  $\text{HCl}$  affords 5-hydroxy-5' : 6'-dimethoxy-7-methyl-6 : 8-diethyl-2 : 3(3' : 2')-indenobenzopyrylium chloride, m.p. 153—154° (perchlorate, m.p. 240—241°). (VII) with  $\text{Zn-Hg}$  in dil.  $\text{HCl}$  containing  $\text{EtOH}$  at 100° affords 2 : 5-dimethyl-4 : 6-diethylresorcinol, m.p. 107—108° (*di-p*-nitrobenzoyl derivative, m.p. 257—259°) (cf. A., 1933, 953). (VI) with malic acid and  $\text{CH}_2\text{Ac}:\text{CO}_2\text{Et}$  in 85%  $\text{H}_2\text{SO}_4$  affords, respectively, 5-hydroxy-7-methyl-6 : 8-diethylcoumarin, m.p. 183—185°, and 5-hydroxy-4 : 7-dimethyl-6 : 8-diethylcoumarin, m.p. 179—180°.

J. L. D.

**Characterisation of quinols. I.** TSUKERVANIK (Bull. Univ. Asie Centrale, 1934, No. 19, 49—60).—Toluquinol and  $\text{Br}$  in  $\text{CHCl}_3$  yield the dibromide, an oil, readily decomp. to yield 2-chloro-5-methylquinol; the tetrabromide, m.p. 138°, prepared similarly, yields di- and tri-bromo-*p*-cresol when heated above the m.p., whilst when it is heated with  $\text{H}_2\text{O}$  the product is 2 : 6-dibromo-5-methylquinol. The di-, m.p. 93° (decomp.), and tetra-chloride, m.p. 143°, prepared analogously, behave similarly to the above bromides, but are more stable. Xyloquinol dibromide, m.p. 108°, tetrabromide, m.p. 138°, dichloride, m.p. 112°, and tetrachloride, an oil, yield unidentified quinols when heated.

R. T.

**Relative directive powers of groups of the forms RO and  $\text{RR}'\text{N}$  in aromatic substitution.** X. Nitration of 4-*tert*-butoxyanisole and 4-*isopropoxy*anisole. L. J. GOLDSWORTHY (J.C.S., 1936, 1148—1150; cf. A., 1931, 479).—The nitration

of 4-*tert*.-butoxyanisole (I), b.p. 112°/10 mm. and 220°/737 mm., prepared by refluxing *p*-OH·C<sub>6</sub>H<sub>4</sub>·OMe (II), Bu<sup>γ</sup>Br, K<sub>2</sub>CO<sub>3</sub>, and COMe<sub>2</sub>, and of 4-isopropoxyanisole, b.p. 103°/12 mm., prepared by refluxing (II), KOH, Pr<sup>β</sup>I, and MeOH, has been studied. The resulting 2- and 3-NO<sub>2</sub>-derivatives are hydrolysed by conc. HCl-AcOH to 2- and 3-nitro-4-methoxyphenol, which are readily separable, thus permitting the calculation of the relative directive powers of OBU<sup>γ</sup> (328) and OPr<sup>β</sup> (229) (OMe—100). These results accord with the theory of Allan *et al.* (A., 1926, 397). A little 2:6-dinitro-4-methoxyphenol was found in the nitration product of (I).  
H. G. M.

**Desmotropy of the phenols as exemplified by Clemmensen reduction.** J. MADINAVEITIA (Anal. Fis. Quím., 1934, 32, 1100—1105).—Unlike the OH-derivatives of C<sub>6</sub>H<sub>6</sub>, those of C<sub>10</sub>H<sub>8</sub> are reduced by Zn-Hg and HCl to hydrocarbons. Differing velocities of reduction of various naphthols are interpreted as due to the presence of differing amounts of the keto-forms. 2-Methyl-1:4-naphthaquinone in Et<sub>2</sub>O is reduced (Zn, 2*N*-H<sub>2</sub>SO<sub>4</sub>) and the product with anhyd. HCN, HCl, and ZnCl<sub>2</sub> gives 1:4-dihydroxy-2-methyl-3-naphthaldehyde, m.p. 195° [*Ac* derivative, m.p. 168°; 2:4-dinitrophenylhydrazone, m.p. 245°; diphenylsemicarbazone, m.p. 215° (previous softening)], reduced to 2:3-dimethyltetrahydronaphthalene. Similarly 2-methyl- and 2:3-dimethyl-1:4-naphthaquinone are reduced to 2-methyl- and 2:3-dimethyl-tetrahydronaphthalene respectively. α-C<sub>10</sub>H<sub>7</sub>·OH is reduced more slowly and β-C<sub>10</sub>H<sub>7</sub>·OH much more slowly to tetrahydronaphthalene. PhOH, *m*- and *p*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, and 1:4:2:5-C<sub>6</sub>H<sub>2</sub>MePr<sup>β</sup>(OH)<sub>2</sub> are not reduced.  
F. R. G.

**Manufacture of condensation products from phenols, formaldehyde, and amines.**—See B., 1936, 684.

**Manufacture of *p*-*N*-*sec*.-alkylaminophenols and other substituted phenols and their salts.**—See B., 1936, 685.

**Manufacture of arylaminophenols.**—See B., 1936, 780.

**Manufacture of halogenated alkenylphenols.**—See B., 1936, 824.

**Preparation of β-formalkylamino-α-*p*-anisylpropanes.**—See B., 1936, 874.

**Manufacture of unsymmetrical dialkyl or alkylaralkyl derivatives of resorcinol.**—See B., 1936, 875.

**Pyrogallol compounds of wood tar.** H. SCHULZ (Ber., 1936, 69, [B], 1870—1873).—Acetylation of a fraction, b.p. 269—271°/760 mm., of wood tar and subsequent distillation yields a viscous liquid from which 2-acetoxy-1:3-dimethoxy-5-ethylbenzene, m.p. 70° (Br<sub>2</sub>-derivative, m.p. 113°), slowly separates. It is hydrolysed to 5-ethylpyrogallol 1:3-Me<sub>2</sub> ether, b.p. 272—274° (Bz derivative, m.p. 114°), the constitution of which is established by its oxidation to 2:6-dimethoxy-*p*-benzoquinone, m.p. 255°, and its demethylation to 5-ethylpyrogallol, m.p. 86—87° (acetate, m.p. 90°). Similar treatment of a wood tar fraction, b.p. 256—260°/760 mm., affords pyrogallol 1-Me ether [4:5:6-Br<sub>3</sub>-derivative, m.p.

111°; Br<sub>1</sub>-, m.p. 138.5°, Br<sub>2</sub>-, m.p. 148°, and Br<sub>3</sub>-, m.p. (?) 121°, -derivatives of 1:2:3-OMe·C<sub>6</sub>H<sub>3</sub>(OAc)<sub>2</sub>]. Analogously the fraction, b.p. 264—266°/760 mm., gives 4:5-diacetoxy-*m*-tolyl Me ether, m.p. 88°, hydrolysed to 5-methylpyrogallol 1-Me ether, m.p. 68°, which immediately reduces AgNO<sub>3</sub> (corresponding 1-Et ether, m.p. 116°); it is obtained synthetically from 5-methylpyrogallol, Me<sub>2</sub>SO<sub>4</sub>, and NaOH. 5-Methylpyrogallol 2-Me ether, m.p. 138° (acetate, m.p. 121°), is described.  
H. W.

**9-Acetamido-2:3:4:6-tetramethoxyphenanthrene.** T. M. SHARP (J.C.S., 1936, 1234—1236).—Trimethylgallaldehyde with conc. H<sub>2</sub>SO<sub>4</sub>-Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub> and HNO<sub>3</sub>-H<sub>2</sub>SO<sub>4</sub> (1:9) (20 min.; -8°) yields 2-nitro-3:4:5-trimethoxybenzaldehyde (I), m.p. 76—77°, together with some 2:6-dimethoxy-*p*-benzoquinone and 4:5-dinitro-1:2:3-trimethoxybenzene. (I) with *p*-OMe·C<sub>6</sub>H<sub>4</sub>·CH<sub>2</sub>·CO<sub>2</sub>Na and Ac<sub>2</sub>O (135°; 8 hr.) affords 2-nitro-3:4:5-trimethoxy-α-*p*-methoxyphenylcinnamic acid, m.p. 170—171°, which with NH<sub>2</sub>-aq. FeSO<sub>4</sub> (1 hr.; 100°) gives the dimorphous 2-NH<sub>2</sub>-compound, m.p. 167—168° and 159°, which in turn with aq. H<sub>2</sub>SO<sub>4</sub>-NaNO<sub>2</sub> affords 2:3:4:6-tetramethoxyphenanthrene-9-carboxylic acid (II), m.p. 172—173°, and a compound, m.p. 162—163°. The crude hydrazide of the Et ester of (II) with 3-8*N*-EtOH-HCl and amyl nitrite yields the azide, which on refluxing with MeOH is converted into the urethane, which with 10% MeOH-KOH (65°; 3.5 hr.) yields 9-amino-2:3:4:6-tetramethoxyphenanthrene, m.p. 157—159° (*Ac* derivative, m.p. 152—153°).  
F. N. W.

**Action of ethyl diazoacetate on thiophenols.** E. MULLER and A. FREYTAG (J. pr. Chem., 1936, [ii], 146, 56—57).—Addition of CHN<sub>2</sub>·CO<sub>2</sub>Et to PhSH at 80° gives Et phenylthiolacetate, b.p. 147.6°/12 mm. Et *p*-tolylthiolacetate, b.p. 157°/14 mm., is obtained similarly.  
H. W.

**Anthrylmercapturic acid.**—See this vol., 1019.

**Action of sodium acetylide on cyclic ketones.** I. Synthesis of 1-acetylenylcyclohexanol. R. J. LEVINA and E. I. VINOGRADOVA (J. Appl. Chem. Russ., 1936, 9, 1299—1302).—cycloHexanone and CNa;CH in Et<sub>2</sub>O give 1-acetylenylcyclohexanol (55% yield), converted by H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> at 120—140° into Δ<sup>1</sup>-cyclohexenylacetylene.  
R. T.

**Hydrogenation of phenylated carbinols.** P. A. LEVENE [with M. KUNA] (J. Biol. Chem., 1936, 115, 275—277).—Although hydrogenation (PtO<sub>2</sub>) of CHPhMe·OH in AcOH gives much PhEt and little cyclohexylmethylcarbinol (I), and the Ph is unaffected in MeOH, (I) is the main product in MeOH-AcOH (9:1). Change of catalyst is without effect. Other Ph derivatives are hydrogenated in MeOH even under pressure without affecting the Ph. The conclusions of Levene *et al.* (A., 1930, 1178) are confirmed.  
R. S. C.

**Compounds related to phenacetin.** (MISS) B. N. KATRAK (J. Indian Chem. Soc., 1936, 13, 334—336).—From *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·ONa and CH<sub>2</sub>Cl·CH<sub>2</sub>·OH was prepared *p*-nitro-β-hydroxy-, m.p. 101—102° (*Ac*, m.p. 85—87°, Bz, m.p. 116°, and salicyl derivatives, m.p. 133°), converted by PCl<sub>5</sub> into β-chloro-*p*-nitro-phenetole, m.p. 67—68°. *p*-Acetamido-, m.p.

116—117° (*Ac* derivative, m.p. 130°), *o*-, b.p. 180—182°/4 mm. (*Ac*, b.p. 201—202°/4 mm. and *Bz* derivatives, m.p. 75—76°), and *m*-nitro- $\beta$ -hydroxyphenetole, m.p. 90—91°, were prepared from the corresponding phenoxide. F. R. S.

**Synthesis of 2 : 4-dihydroxymethylanisole and of some derivatives.** R. QUELET and M. ANGLADE (Compt. rend., 1936, 203, 262—264).—PhOMe with CH<sub>2</sub>O saturated with HCl gas at 0° affords a product which when treated similarly, but at 75°, gives 2 : 4-dichloromethylanisole (I), m.p. 66°, oxidised (KMnO<sub>4</sub>) to 4-methoxyisophthalic acid (A., 1929, 65). (I) with NaOAc in hot AcOH affords 2 : 4-diacetoxymethylanisole, m.p. 47—48°, hydrolysed (20% EtOH-KOH at room temp.) to 2 : 4-dihydroxymethylanisole, m.p. 100—101° (phenylcarbamate, m.p. 152°; Me<sub>2</sub>, Et<sub>2</sub>, Pr<sub>2</sub>, Bu<sub>2</sub>, and diisooamyl ethers, b.p. 155°/18 mm., 166°/16 mm., 183°/17 mm., 178°/6 mm., and 188°/7 mm., respectively). J. L. D.

**Lederer-Manasse reaction. Synthesis of vanillyl alcohol.** G. GOETHALS (Natuurwetensch. Tijds., 1936, 18, 249—255).—Guaiacol and CH<sub>2</sub>O react in NaOH solution to give vanillyl alcohol, 1-methoxy-2 : 4-di(hydroxymethyl)phenol, m.p. 105—106° (dibromide, m.p. 127—127.5°), and 4 : 4'-dihydroxy-3 : 3'-dimethoxy-5 : 5'-di(hydroxymethyl)diphenylmethane, m.p. 146.5—147° (dibromide, m.p. 181—183°). S. C.

**$\beta$ -Cholesterol.** E. A. EVANS, jun., and R. SCHOENHEIMER (J. Biol. Chem., 1936, 115, 17—18).—The portion of " $\beta$ -cholesterol" (I) (A., 1932, 844) not pptd. by digitonin affords  $\Delta^2$ -cholestadiene and is epiallocholesterol (II). (II) and dihydrocholesterol give a mol. compound identical with (I), but with const. m.p. 154°; the m.p. 160° previously (A., 1908, i, 164) reported for (I) is probably due to the presence of cholesterol pinacone. R. S. C.

**Constitution of cholesterol. XII. Isomerisation by monochloroacetic acid.** F. PIRRONE (Gazzetta, 1936, 66, 398—404).—Cholesterol and CH<sub>2</sub>Cl-CO<sub>2</sub>H mixed in CHCl<sub>3</sub> and exposed to sunlight, or fused together at 125—155°, yield an isocholesterol (metacholesterol ?) (I), m.p. 139—140°, and its monochloroacetate (II), m.p. 159—161°, which with Br in AcOH gives a dibromodihydro-derivative, m.p. 110—111°. (II) is converted by NaOAc into (I): it is not affected by NH<sub>3</sub>. With Ac<sub>2</sub>O (I) and (II) give a product of which the m.p. is not depressed on admixture with that derived from cholesterol or its *Ac* derivative. E. W. W.

**Constitution of vitamin-D<sub>2</sub>. II.** A. WINDAUS and W. GRUNDMANN (Annalen, 1936, 524, 295—299; cf. this vol., 69).—Oxidation of vitamin-D<sub>2</sub> (I) by KMnO<sub>4</sub> yields small amount of HCO<sub>2</sub>H, whilst small quantities of CH<sub>2</sub>O are obtained by its ozonisation. The results are not considered to establish the presence of :CH<sub>2</sub> since somewhat similar experience results with ergosterol from which :CH<sub>2</sub> is absent. From the KMnO<sub>4</sub> oxidation a ketone, C<sub>19</sub>H<sub>32</sub>O (semicarbazone, m.p. 222°; oxime, m.p. 107°), is isolated, which is hydrogenated (spongy Pd in Et<sub>2</sub>O) to the ketone of

Windaus *et al.* (*loc. cit.*) and hence has the constitution A (R=CHMe·CH:CH·CHMePr <sup>$\beta$</sup> ).

Ozonisation of (I) in AcOH and fission of the ozonide with steam affords the acid (*A* with R=CHMe·CO<sub>2</sub>H), m.p. 124°. These results with those of Heilbron *et al.* (A., 1935, 1036, 1235) are considered to support the author's formulation of (I). The contrary views of Bernal *et al.* (A., 1935, 1120) are not explained.

H. W.

**Oestrogenic activity of synthetic polycyclic compounds.** J. W. COOK, E. C. DODDS, and W. LAWSON (Proc. Roy. Soc., 1936, B, 121, 133—141).—Tests for oestrogenic activity have been carried out with 18 diols, prepared by the action of Grignard reagents on polycyclic quinones. Substances of higher activity than 9 : 10-dihydroxy-9 : 10-di-*n*-propyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene have not been found. In the dibenzanthracene series the effects of branching and cyclisation of the alkyl-group have been studied. Diols with polynuclear skeletons other than dibenzanthracene may show some activity. In the 9 : 10-dihydroxy-9 : 10-di-alkyl- (or -aryl)-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene series, the isopropyl, m.p. 288—290°, allyl-, m.p. 210—211°, isobutyl-, m.p. 212°, cyclopentyl-, m.p. 281—282°, cyclohexyl-, m.p. 279—280°, and phenyl-, m.p. 346°, compounds were prepared. In the corresponding 9 : 10-dihydroanthracene series the allyl-, m.p. 111—112°, *n*-propyl-, m.p. 171—172°, *n*-butyl-, m.p. 158°, *n*-amyl-, m.p. 179—180°, and cyclopentyl-, m.p. 216°, compounds were prepared. Other new substances prepared were 9 : 10-dihydroxy-9 : 10-di- $\alpha$ -naphthyl-9 : 10-dihydrophenanthrene, m.p. 265—266°, 1 : 2-dihydroxy-1 : 2-di-*n*-propyl-, m.p. 145°, and -di-*n*-amyl-1 : 2-dihydrochrysene, m.p. 107—108°, 9 : 10-dihydroxy-9 : 10-diphenyl-9 : 10 : 1' : 2' : 3' : 4'-hexahydro-1 : 2-benzanthracene, m.p. 230—231°, 9 : 10-dihydroxy-9 : 10-di-*n*-butyl-, m.p. 154°, and -9 : 10-diphenyl-9 : 10 : 1' : 2' : 3' : 4'-hexahydro-2 : 3-benzanthracene, m.p. 222—223°. 1-Hydroxy-1 : 2 : 3 : 4-tetrahydrophenanthrene, m.p. 100—101° (acetate, m.p. 63—64°), was obtained by hydrogenation of the corresponding keto-compound. Further hydrogenation gave *s*-octahydrophenanthrene. E. A. H. R.

**Constituents of hinokiol. II. Comparison of hinokin and cubebinolide. III. Constitution of hinokiol. IV. Structure of hinokiol.** S. KEIMATSU and T. ISHIGURO (J. Pharm. Soc. Japan, 1935, 55, 96—99, 99—105, 186—195).—II. Comparison of derivatives leads to the conclusion that hinokin is identical with cubebinolide (Steer, Annalen, 1840, 36, 331). Diphenylhinokin has m.p. 138°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —172.4° in CHCl<sub>3</sub>.

III. Reduction of hinokiol (HI-red P) yields a substance (I), C<sub>19</sub>H<sub>32</sub>, b.p. 320—335°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +5.50°, containing one double linking, and another substance, b.p. 290—310°, also obtained by further reduction of

(I). Dehydrogenation (Se at 280—320°) of (I) gives retene (?), m.p. 95—98°.

IV. Dehydrogenation (Se at 280—340°) of hinokiol affords (probably) retene, m.p. 98—99°, hydroxyretene, m.p. 176—177° (picrate, m.p. 176—177°), and dihydroxyretene, m.p. 234—235°. Adopting the mol.

formula  $C_{19}H_{28}O_2$  for hinokiol, the appended structure is suggested.

CH. ABS. (r)

**Sterols and bile acids.** U. WESTPHAL (Chem. Ztg., 1936, 60, 774—777).—A review.

**Fixed oil of poke root.**—See this vol., 1306.

**Seed oil of *Cuscuta reflexa*, Roxb.**—See this vol., 1166.

**cycloHexane series.** II. Formation of isomeric arylaminocyanomethylcyclohexanes in the condensation of the cyanohydrins of the methylcyclohexanones with arylamines. M. W. BUKSHI, R. D. DESAI, R. F. HUNTER, and M. HUSSAIN (J.C.S., 1936, 1159—1161; cf. this vol., 846).—Condensation of 4-methylcyclohexanone cyanohydrin with  $NH_2Ph$ ,  $p-C_6H_4Br.NH_2$ ,  $o-$  (I),  $m-$ , and  $p-C_6H_4Me.NH_2$ ,  $\alpha-$  and  $\beta-C_{10}H_7.NH_2$  yields [with the exception of (I)] pairs of isomeric arylaminocyanomethylcyclohexanes  $CHMe \begin{smallmatrix} \text{CH}_2 \cdot \text{CH}_2 \\ \text{CH}_2 \cdot \text{CH}_2 \end{smallmatrix} \begin{smallmatrix} \text{C} \cdot \text{CN} \\ \text{C} \cdot \text{NHR} \end{smallmatrix}$ . The

following are described, with the corresponding carboxylic acids and their amides, the recorded m.p. being for the A and B forms, respectively:  $R=Ph$ , m.p. 107° and 92—93° [A amide, m.p. 166° (lit. 161°); B amide, m.p. 174°; A acid, m.p. 186° (lit. 179°)];  $p-C_6H_4Br$ , m.p. 126° and 88—89° (amides, m.p. 178° and 158°; A acid, m.p. 184°);  $p-$ , m.p. 104° and 79° (amides, m.p. 155° and 145°),  $m-$ , m.p. 115° and 82—83° (amides, m.p. 137—138° and 117—118°),  $o-C_6H_4Me$ , m.p. 100° (amide, m.p. 143°);  $\alpha-$ , m.p. 151—152° and 165° (amides, m.p. 138° and 204°),  $\beta-C_{10}H_7$ , m.p. 152° and 132° (amides, m.p. 270° and 205°). The 3-methyl compounds are obtained similarly:  $Ph$ , m.p. 75° and 95° (amides, m.p. 97° and 92°);  $p-C_6H_4Br$ , m.p. 88—89° (amide, m.p. 137°);  $p-$ , m.p. 78° (amide, m.p. 165°),  $o-C_6H_4Me$ , m.p. 86°;  $\alpha-$ , m.p. 137° (amide, m.p. 169°), and  $\beta-C_{10}H_7$ , m.p. 136° (amide, m.p. 186°); and the following 2-methyl compounds:  $R=Ph$ , m.p. 126° and 88° (amides, m.p. 128° and 147°; A acid, m.p. 187°);  $p-C_6H_4Br$ , m.p. 99° (amide, m.p. 154°);  $p-$ , m.p. 140° (amide, m.p. 185°),  $m-$ , m.p. 101° (amide, m.p. 112°), and  $o-C_6H_4Me$ , m.p. 121°;  $\alpha-$ , m.p. 118°, and  $\beta-C_{10}H_7$ , m.p. 110—111° and 105° (A amide, m.p. 178°).

F. N. W.

**Mechanism of amination by sodamide.** II. Formation of unsubstituted aromatic amidines by the action of sodamide on aromatic nitriles. A. KRSSANOV and I. POLJAKOVA (Bull. Soc. chim., 1936, [v], 3, 1600—1606; cf. this vol., 198).— $NaNH_2$  and aromatic nitriles give amidines, best isolated as carbonates, thus proving that reaction of  $NaNH_2$  also with  $C_5H_5N$  and Schiff's bases occurs by addition to the C.N. The following are prepared, best in  $PhMe$  at 150°. Benz. [carbonate, m.p. 91—94°;

platinichloride, m.p. 192—194° (corr.); salicylate, m.p. 200—203°; picrate, m.p. 228—232° (cf. lit.)],  $p$ -tolu. [carbonate, m.p. 118—122°; picrate (I) (prep. in  $C_6H_6$ ), decomp. 219°; salicylate, m.p. 210—220°; platinichloride, m.p. 198° (cf. lit.)], and  $\beta$ -naphth-amidine, m.p. 133—136° (lit. 145°) [carbonate, m.p. 128—132°; platinichloride, m.p. 199—202° (cf. lit.)].  $MeCN$  and  $NaNH_2$  react violently, but no amidine could be isolated. Crystallisation of (I) from  $EtOH$  gives  $\omega$ -ethoxytolualdimine picrate. Cornell's salts (A., 1929, 173) were probably mixtures of nitriles and sodalkamides. R. S. C.

**p-Phenylphenacyl esters of organic acids.** T. L. KELLY and E. A. MORISANI (J. Amer. Chem. Soc., 1936, 58, 1502—1503).—The following are prepared by the method of Drake *et al.* (A., 1932, 745):  $p$ -phenylphenacyl  $m-$ , m.p. 155°, and  $p-$ , m.p. 160°, -bromo-,  $o-$ , m.p. 123°,  $m-$ , m.p. 154°, and  $p-$ , m.p. 160°, -chloro-,  $o-$ , m.p. 143°,  $m-$ , m.p. 147°, and  $p-$ , m.p. 171° (sealed tube), -iodo-,  $o-$ , m.p. 140°, and  $m-$ , m.p. 153°, -nitro-, and  $p$ -cyano-, m.p. 165°, -benzoates;  $o-$ , m.p. 146°,  $m-$ , m.p. 193°, and  $p-$ , m.p. 192°, -nitrocinnamates; diphenylacetate, m.p. 111°. H. B.

**Synthesis of derivatives of s-diphenylethane related to materials occurring naturally.** I. **Synthesis of ring system proposed for calciferol.** S. NATIELSON and S. P. GOTTFRIED (J. Amer. Chem. Soc., 1936, 58, 1432—1438).—Benzylidenephthalide [from  $CH_2Ph.CO_2H$  and  $o-C_6H_4(CO_2O)$  at  $>240^\circ$ ; cf. Org. Synth., 1933, 13, 10] is reduced (Na-Hg, aq. KOH) to benzylphthalide, m.p. 61°, which when dissolved in  $EtOH-KOH$ , the  $EtOH$  subsequently evaporated, and the residue heated at 180°, gives stilbene- $o$ -carboxylic acid, m.p. 160°. This is reduced (Na-Hg on aq. Na salt) to  $o$ - $\beta$ -phenylethylbenzoic [s-diphenylethane- $o$ -carboxylic] acid, m.p. 130° [chloride (I), b.p. 202°/20 mm., m.p. 50—55°, obtained from  $SOCl_2$  and the Hg-free acid only; Et ester (II), b.p. 205°/18 mm.; anilide (III), m.p. 137°, from (I) and  $NH_2Ph$  at 90° or the acid and  $NH_2Ph$  at  $<240^\circ$ ]. (I) and  $NaOAc$  in  $Ac_2O$  at 180° afford  $o$ - $\beta$ -phenylethylbenzoic acetic anhydride, m.p. 95°, whilst reduction (Na and  $Bu^oOH$  in  $PhMe$ ) of (II) gives products, b.p. 177°/20 mm. and 195°/20 mm. (III) and  $PCl_5$  followed by anhyd.  $SnCl_2$  in  $Et_2O-HCl$  give a complex,  $C_{21}H_{20}NCl_3Sn$ , decomp. 213°, hydrolysed (dil. HCl) to  $o$ - $\beta$ -phenylethylbenzaldehyde (IV) (phenylhydrazone, m.p. 95°), which with  $CH_2(CO_2H)_2$  and  $C_5H_5N$  at 90° yields  $o$ - $\beta$ -phenylethylcinnamic acid (V), m.p. 149—150°, reduced (Na-Hg, aq.  $Na_2CO_3$ ) to  $\beta$ - $o$ -phenylethylphenylpropionic [s-diphenylethane- $o$ - $\beta$ -propionic] acid (VI), m.p. 110—111°. (IV),  $Ac_2O$ , and  $NaOAc$  or  $KOAc$  at 180—200° give some (V) and (mainly)  $o$ - $\beta$ -phenylethylbenzylidene diacetate, m.p. 85°, which with  $NaOAc$  and  $AcOH$  at 200° affords (V). The chloride, b.p. 155—165° (bath)/0.002—0.004 mm., of (VI) with  $AlCl_3$  in light petroleum yields 4- $\beta$ -phenylethyl-1-indanone, not obtained cryst. [oxime, m.p. 135°, reduced (Na,  $EtOH$ ) to 1-amino-4- $\beta$ -phenylethylindane (hydrochloride, m.p. 192°)], reduced (Clemmensen) to 4- $\beta$ -phenylethylindane, b.p. 115—120°/0.0001 mm., which has the ring-system proposed (lit.) for calciferol and tachysterol. H. B.

Esters of triphenylpropionic acid and their application to the identification of alcohols. A. GARCÍA BANUS and F. BOQUÉ (Anal. Fis. Quim., 1935, 33, 72—80).— $\text{MgCl} \cdot \text{CH}_2\text{Ph}$  and  $\text{RCHO}$  (R is Ph or  $p\text{-C}_6\text{H}_4\text{OMe}$ ) with  $\text{CHPhCl} \cdot \text{COCl}$  yield  $\text{CHPhCl} \cdot \text{CO}_2\text{CHR} \cdot \text{CH}_2\text{Ph}$ , which when distilled at 20 mm. gives  $\text{CHPh} \cdot \text{CHR}$  and  $\text{CH}_2\text{PhCl}$ .  $\text{CPh}_2 \cdot \text{CHPh} \cdot \text{CO}_2\text{H}$  (improved prep.) with  $\text{SOCl}_2$  gives the *chloride*, m.p. 94°, which with  $\text{MgCl} \cdot \text{CH}_2\text{Ph}$  and  $\text{PhCHO}$  yields the  $\alpha\beta$ -diphenylethyl ester, m.p. 114°, and with  $\text{MgPrBr}$  and  $\text{COMeEt}$  the  $\beta$ -methyl- $\beta$ -ethylbutyl ester, m.p. 170° (also obtained from  $\text{CMeEtPr} \cdot \text{OH}$ ), and with the appropriate alcohol gives the following esters:  $\text{Pr}^\alpha$ , m.p. 109°,  $\text{Pr}^\beta$ , m.p. 138°,  $\text{Bu}^\alpha$ , m.p. 99°,  $\text{Bu}^\beta$ , m.p. 84°, *amyl*, m.p. 92.5°, *isoamyl*, m.p. 72°, *sec.-amyl*, m.p. 114°, *sec.-isoamyl*, m.p. 63°,  $[\alpha]_D + 85.4^\circ$  in  $\text{EtOH}$ ,  $\alpha$ -methylbutyl, m.p. 60°, *hexyl*, m.p. 92°, *heptyl*, m.p. 95.5°, *octyl*, m.p. 74°, *nonyl*, m.p. 77°, *decyl*, m.p. 78°, *undecyl*, m.p. 93.5°, *dodecyl*, m.p. 88°, *cetyl*, m.p. 62°, *octadecyl*, m.p. 70°,  $\alpha$ -ethylpropyl, m.p. 104°, *allyl*, m.p. 108°, *Ph*, m.p. 124°, *bornyl*, m.p. 173°, *benzyl*, m.p. 117°, *menthyl*, m.p. 138°,  $[\alpha]_D - 96.5^\circ$  in  $\text{EtOH}$ . The *menthylamine* salt has m.p. 125°,  $[\alpha]_D - 33^\circ$  in dil.  $\text{EtOH}$ . F. R. G.

Manufacture of aromatic or heterocyclic carboxylic acid amides of high mol. wt.—See B., 1936, 875.

Action of acetylene on ethyl acetoacetate in presence of mercury salts. B. CIOCCA and (SIGNA.) M. SCATTOLA (Gazzetta, 1936, 66, 394—398).— $\text{CH}_3\text{Ac} \cdot \text{CO}_2\text{Et}$  treated with  $\text{C}_2\text{H}_2$  under slight pressure in  $\text{H}_2\text{SO}_4$  containing Hg salts reacts violently, after an induction period, and gives  $\text{Et } 2:6\text{-dimethyl-}\Delta^2\text{-cyclohexen-4-one-1-carboxylate}$ ,  $\text{Et}_2 2:4\text{-dimethyl-}\Delta^4\text{-cyclohexen-6-one-1:3-dicarboxylate}$ , and  $\text{Et ethylideneacetoacetate}$ . E. W. W.

Modification of the Clemmensen method of reduction. E. L. MARTIN (J. Amer. Chem. Soc., 1936, 58, 1438—1442).—Improved results in the reduction of many  $\beta$ -aroylpropionic acids by the Clemmensen method are often obtained by addition of a layer of  $\text{PhMe}$  to the reaction mixture. The same modification is advantageous in the reduction (Zn dust, aq.  $\text{NaOH}$ ) of anthrones to anthracenes. It is suggested that Clemmensen reduction occurs thus:  $\text{CO} \rightarrow \text{CH}(\text{OH})$ ,  $\text{CHCl} \rightarrow \text{CH}_2$ ; this view is supported by the ready production of  $\text{CH}_2\text{Ph} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$  from  $\gamma$ -phenyl- $\gamma$ -butyrolactone.

$\beta$ -m-Nitrobenzoylpropionic acid, m.p. 162—164° (*Me* ester, m.p. 68—69°), from  $\text{CH}_2\text{Bz} \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ ,  $\text{HNO}_3$  (d 1.5), and conc.  $\text{H}_2\text{SO}_4$  at  $-10^\circ$  to  $0^\circ$  and then at  $15^\circ$ , is reduced (aq.  $\text{NH}_4\text{HS}$  at  $<50^\circ$ ) to the *m-NH*<sub>2</sub>-derivative, m.p. 131—132° [*hydrochloride*, m.p.  $>250^\circ$  (decomp.) (all m.p. except this are corr.)], converted (diazo-method) into  $\beta$ -m-hydroxybenzoylpropionic acid, m.p. 144—145° [*semicarbazone*, m.p. 198—200°; *Me* ether, m.p. 107—108° (lit. 110—111°), reduced (as above) in small quantities to  $\gamma$ -m-anisylbutyric acid (60% yield)].  $p\text{-C}_6\text{H}_4\text{Me} \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$  similarly leads to  $\beta$ -3-nitro-, m.p. 148—150° (*Me* ester, m.p. 50—51°),  $\beta$ -3-amino-, m.p. 148—149° [*hydrochloride* (+ $\text{H}_2\text{O}$ )],

m.p. 144—146°,  $\beta$ -3-hydroxy-, m.p. 172—173° (*semicarbazone*, m.p. 188—190°), and  $\beta$ -3-methoxy-, m.p. 120—121° (*semicarbazone*, m.p. 172—173°), 4-methylbenzoylpropionic acids and thence  $\gamma$ -3-methoxy-4-methylphenylbutyric acid, m.p. 70—71° (86% yield).

H. B.

Ultra-violet absorption spectra of thyroxine, thyronine, tyrosine, di-iodotyrosine, and thyroglobulin. L. J. HEIDT (J. Biol. Chem., 1936, 115, 223—225).—The spectra were all sufficiently similar to prevent a differential detection of these substances spectrographically.

H. D.

Octylsalicylic acid.—See B., 1936, 685.

6-Nitro- and 6-amino-2:3-hydroxynaphthoic acid.—See B., 1936, 686.

Manufacture of a new 5-hydroxyhydrindene-carboxylic acid and derived amides.—See B., 1936, 825.

Preparation of lithocholic acid from cholesterol. R. SCHOENHEIMER and (MISS) F. BERLINER (J. Biol. Chem., 1936, 115, 19—24).—The dibromide of *Me* 3-hydroxy- $\Delta^5$ -cholenate and  $\text{CrO}_3$  give a product, which with  $\text{NaI} \cdot \text{MeOH}$  affords *Me*  $\Delta^4$ -cholen-3-onate (I) (55% yield), m.p. 125° [*semicarbazone*, m.p. 229° (decomp.)], hydrolysed to the corresponding acid (II), m.p. 185—186°, the absorption spectrum (max. at 240  $\text{m}\mu$ ) of which proves the position of the ethylenic linking. With  $\text{H}_2$ - $\text{PtO}_2$  in  $\text{EtOH} \cdot \text{Et}_2\text{O}$  (I) gives 80% of *Me* lithocholate and 20% of *Me* 3-hydroxyallocholate, separable by digitonin. With  $\text{H}_2$ -Pd (II) gives a difficulty separable mixture of much 3-keto- with a little 3-ketoallocholic acid. Thus hydrogenation of the CO occurs solely in such a way that the OH formed is *trans* to the H in position 5.

R. S. C.

Synthesis of *dl-cis*- and *-trans*-1-isopropylcyclopropane-1:2-dicarboxylic acids and a resolution of the *cis*-acid. Synthesis of umbellulanic acid. S. K. RANGANATHAN (Current Sci., 1936, 5, 20, and J. Indian Chem. Soc., 1936, 13, 419—425).— $\text{CH}_2\text{CPr}^\beta \cdot \text{CO}_2\text{Et}$  and  $\text{CHN}_2 \cdot \text{CO}_2\text{Et}$  give  $\text{Et}_2$   $\alpha$ -isopropyl- $\Delta^1$ -pyrazoline-3:5-dicarboxylate, b.p. 158°/1 mm., which at 200° loses to form the mixed  $\text{Et}_2$  ester of *dl-trans*-1-isopropylcyclopropane-1:2-dicarboxylic acid (cf. this vol., 993), from which ( $\text{AcCl}$ ) the *cis-anhydride*, b.p. 140°/20 mm., and *cis*-acid (*p-tolil*, m.p. 89°) are obtained (cf. *loc. cit.*). The *d-cis*-acid is isolated through the *brucine* salt (+9 $\text{H}_2\text{O}$ ),  $[\alpha]_D^{20} - 25.63^\circ$  in  $\text{EtOH}$ , and the *l-cis*-acid (*umbellulanic acid*) through the *cinchonidine* salt.

E. W. W.

Introduction of substituents into the cyclopentadiene nucleus. I. 1- and 2-Benzylcyclopentadiene. K. ALDER and H. HOLZRICHTER (Annalen, 1936, 524, 145—180).—*cyclopentadiene* in  $\text{C}_6\text{H}_6$  is treated successively with K and  $\text{CH}_2\text{PhCl}$  giving unchanged material, a mixture (I) of 1-,  $\text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{C} \cdot \text{CH}_2\text{Ph}$ , and 2-benzylcyclopentadiene,  $\text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{C} \cdot \text{CH}_2\text{Ph}$ , and *dibenzylcyclopentadiene* (II),  $\text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{CH}=\text{CH} \cdot \text{C} \cdot \text{CH}_2\text{Ph}$ , b.p. 200—210°/13 mm., which readily passes into a *dimeride*, m.p. 88°. (I) does not yield  $\text{Ph}_2$  when

heated with Se at 300°, thus excluding the possibility of the presence of cyclohexadiene derivatives. Treatment of (I), b.p. 115—120°/13 mm., after being depolymerised by heating for some time at 115°, with maleic anhydride in dry Et<sub>2</sub>O affords 3-benzyl-3:6-endomethylene- $\Delta^4$ -tetrahydrophthalic anhydride (III), m.p. 123° [corresponding acid (IV), m.p. 165° (decomp.)], and 4-benzyl-3:6-endomethylene- $\Delta^4$ -tetrahydrophthalic anhydride (V), m.p. 80°, best isolated through the Na<sub>2</sub> salt of the corresponding acid (VI), m.p. 154—155° (decomp.). Catalytic hydrogenation of (V) (colloidal Pd) yields 4-benzyl-3:6-endomethylenehexahydrophthalic acid, m.p. 153°, whereas (VI) in presence of PtO<sub>2</sub> gives 4-cyclohexylmethyl-3:6-endomethylenehexahydrophthalic acid, m.p. 159° (decomp.). Oxidation of (V) with 4% KMnO<sub>4</sub> gives BzOH and *cis-cis-cis-cis*-cyclopentane-1:2:3:4-tetracarboxylic acid. (V) with 50% H<sub>2</sub>SO<sub>4</sub> at room temp. gives the lactonic acid (VII), m.p. 189° (*Me* ester, m.p. 126°), isomerised by NaOMe to the

156°, also obtained by the action of CH<sub>3</sub>Ph·MgCl on trans-4-keto-3:6-endomethylene-

hexahydrophthalic acid, thus establishing the position of the CH<sub>2</sub>Ph. Ozonisation of (V) in EtOAc at 0° and treatment of the solution with H<sub>2</sub>-Pd-CaCO<sub>3</sub> gives the "O<sub>5</sub> substance," C<sub>16</sub>H<sub>14</sub>O<sub>5</sub>, m.p. 203—204°, and (?) CH<sub>2</sub>Ph·CO<sub>2</sub>H.

Hydrogenation of (IV) (colloidal Pd) yields 3-benzyl-3:6-endomethylenehexahydrophthalic acid, m.p. 169° (decomp.) (anhydride, m.p. 83°), whereas in presence of PtO<sub>2</sub> 3-cyclohexylmethyl-3:6-endomethylenehexahydrophthalic acid, m.p. 144—145° (anhydride, m.p. 81°), is produced. Treatment of (III) with boiling MeOH gives two *Me* H esters, m.p. 165° and m.p. 114°, respectively, thus proving that CH<sub>2</sub>Ph is unsymmetrically placed with respect to

$\begin{matrix} \text{C}=\text{CO} \\ \text{C}=\text{CO} \end{matrix} \text{O}$  and establishing the constitution of (III). Either ester is transformed by CH<sub>3</sub>N<sub>3</sub> into the non-cryst. *Me*<sub>3</sub> ester, isomerised by NaOMe and then hydrolysed to the *trans*-acid, C<sub>16</sub>H<sub>16</sub>O<sub>6</sub>, m.p. 204—205°. (III) and 50% H<sub>2</sub>SO<sub>4</sub> give the lactonic acid, m.p. 239—240° (*Me* ester, m.p. 86°). With PhN<sub>3</sub> in EtOAc (III) yields the hydrotriazole, m.p. 239°. (III) with 4% KMnO<sub>4</sub> gives *cis-cis-cis-cis*-1-benzylcyclopentane-1:2:3:4-tetracarboxylic acid, m.p. 197° (*mono*-, m.p. 216°, and *di*-, m.p. 161°, -anhydride); milder conditions lead to the (OH)<sub>4</sub>-acid, (VIII), m.p. 216°

(decomp.) (*mono*-, m.p. 132°, and *di*-, m.p. 111°, -acetyl anhydride), and (IX), oxidised to a stereo-isomeric 1-benzylcyclopentane-1:2:3:4-tetracarb-

oxylic acid, m.p. 232°, transformed by AcCl only into a monoanhydride, m.p. 234—235°. The formation of 1- and 2-CH<sub>2</sub>Ph derivatives in place of the expected 5-compound is explained by assuming K cyclopentadiene to be heteropolar with a symmetrically constituted anion. (I) with (C·CO<sub>2</sub>H)<sub>2</sub> in Et<sub>2</sub>O gives a mixture of 3- and 4-benzyl-3:6-endomethylene- $\Delta^{1:4}$ -dihydrophthalic acids, best separated from one another by partial hydrogenation (colloidal Pd) of their Na salts to 4-benzyl-3:6-endomethylene- $\Delta^1$ -tetrahydrophthalic acid (X), m.p. 217—218° (anhydride, m.p. 99—100°, and its adduct, C<sub>22</sub>H<sub>19</sub>O<sub>3</sub>N<sub>3</sub>, m.p. 155°, with PhN<sub>3</sub>), and the corresponding 3-CH<sub>2</sub>Ph acid, m.p. 185—186° (anhydride, m.p. 63—64°, and its adduct, m.p. 206°). Further hydrogenation (PtO<sub>2</sub>) of (X) gives the acid, m.p. 159°, derived from (VI), thus establishing the constitution and proving that the union of H to the double linking of (X) takes place in the *exo* position. Addition of maleic anhydride to (II) gives the compound, C<sub>28</sub>H<sub>22</sub>O<sub>4</sub>, m.p. 190°. H. W.

Oxidation of double linkings. I. Oxidation of *endo-cis*-3:6-endomethylene- $\Delta^4$ -tetrahydrophthalic acid. K. ALDER and S. SCHNEIDER (Annalen, 1936, 524, 189—202).—Oxidation of *endo-cis*-3:6-endomethylene- $\Delta^4$ -tetrahydrophthalic acid (I) by 4% KMnO<sub>4</sub> without particular precautions gives *cis-cis-cis-cis*-cyclopentane-1:2:3:4-tetracarboxylic acid (II), m.p. 195° (decomp.), converted by boiling AcCl into the dianhydride, m.p. 222°. Under milder conditions and in alkaline solution the products are 4:5-dihydroxy-3:6-endomethylenehexahydrophthalic acid (III) (diacetyl-anhydride, m.p. 161—

162°) and the neutral O<sub>5</sub> substance (IV), m.p. 263° (decomp.), which is the main product when oxidation is effected in acid solution. (IV) is neutral, and indifferent towards CH<sub>2</sub>N<sub>2</sub>, boiling Ac<sub>2</sub>O, and cold aq. Na<sub>2</sub>CO<sub>3</sub>. When dissolved in hot aq. Na<sub>2</sub>CO<sub>3</sub> it is oxidised by KMnO<sub>4</sub> to (II). It is therefore regarded as formed by threefold loss of H<sub>2</sub>O from the hydrated form of 3:5-dialdehydocyclopentane-1:2-dicarboxylic acid. The conclusion is supported by the observation that it is converted by NHPh·NH<sub>2</sub> into the diphenylhydrazonodiphenylhydrazide, m.p. 224—225°, of this acid and is formed by the treatment of (III) with Pb(OAc)<sub>4</sub> in AcOH and by the ozonisation of (I). Oxidation of *endo-cis*-3:6-endomethylene- $\Delta^4$ -tetrahydrophthalic anhydride by Pb(OAc)<sub>4</sub> in AcOH gives the dilactone (V), m.p. 266°. (I) and 30% H<sub>2</sub>O<sub>2</sub> in H<sub>2</sub>SO<sub>4</sub>-AcOH afford 4-hydroxy(*endo*)-5-hydroxy(*exo*)-*cis*-3:6-endomethylenehexahydrophthalic acid (corresponding lactone and its *Ac* derivative, m.p. 150—151°, and *Ac Me* ester, m.p. 65°). H. W.

**cycloHexane series. III. 1-Carboxy-3:3-dimethylcyclohexane-1-acetic acid.** R. D. DESAI, M. O. FAROOQ, and R. F. HUNTER (J.C.S., 1936, 1162—1163).—1-Carboxy-3:3-dimethylcyclohexane-1-acetic acid (I), m.p. 166° (effervescence) (Ba, Ca, Pb, and Cu salts; anhydride, m.p. 67°; anilic acid, m.p. 205°; anil, m.p. 132°), together with its imide, m.p. 204°, an amic acid, m.p. 145° [hydrolysed to (I)], and a compound, m.p. 85—86°, result from the hydrolysis (conc. HCl; 48 hr.) of the dinitrile obtained by the interaction of aq. KCN and Et 3:3-dimethylcyclohexylidene-1-cyanoacetate, b.p. 155—157°/14 mm. [from 3:3-dimethylcyclohexanone (II) and CN·CH<sub>2</sub>·CO<sub>2</sub>Et in presence of piperidine and Na<sub>2</sub>SO<sub>4</sub> (48 hr.; 100°)]. (II) with aq. KCN and NaHSO<sub>3</sub> affords 1-hydroxy-1-cyano-3:3-dimethylcyclohexane, b.p. 128—129°/15 mm., which with CN·CHNa·CO<sub>2</sub>Et (24 hr., room temp., and 2 hr., 100°) yields Et 1-cyano-3:3-dimethylcyclohexane-1-α-cyanoacetate, b.p. 190—191°/15 mm., hydrolysed (HCl; 48 hr.) to (I). F. N. W.

**Diene synthesis. I. Direct differentiation of cyclic penta- and hexa-dienes.** K. ALDER and H. F. RICKERT (Annalen, 1936, 524, 180—189).—The readiness of addition of PhN<sub>3</sub> to the simpler cyclopentadienes (I) is much > to cyclohexadienes (II), but the difference in rate tends to disappear in the presence of heavy substituents. Adducts of (I) and maleic anhydride (III) dissociate into their components when heated whereas those of (II) afford (·CH<sub>2</sub>·CO)<sub>2</sub>O and a C<sub>6</sub>H<sub>6</sub> derivative. With complex derivatives of (I) decomp. frequently occurs with liberation of H, which converts (III) into (·CH<sub>2</sub>·CO)<sub>2</sub>O, so that the isolation of the latter is not a certain criterion of the presence of (II). A safer guide is found in (·C·CO<sub>2</sub>R)<sub>2</sub>, the adducts of which with (I) dissociate when distilled into their components, which re-unite in the receiver giving esters which are hydrolysed to acids identical with those obtained by the direct union of (I) with (·C·CO<sub>2</sub>H)<sub>2</sub>. Derivatives of (II) when distilled yield C<sub>6</sub>H<sub>4</sub> and ester of phthalic acid or its derivatives readily identified after hydrolysis. The following transformations are cited: α-phellandrene to 4-methylphthalic acid; cyclohexadiene to o-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>, also obtained from trans-1:2-dihydrophthalic acid; 2-benzylcyclopentadiene to 4-benzyl-3:6-endomethylene-Δ<sup>1,4</sup>-dihydrophthalic acid, m.p. 232°, identified by partial hydrogenation (colloidal Pd) to 4-benzyl-3:6-endomethylene-Δ<sup>1</sup>-tetrahydrophthalic acid, m.p. 218°. H. W.

**Reaction of phthalic anhydride with glycerol.** A. I. KOGAN (J. Appl. Chem. Russ., 1936, 9, 1070—1081).—Condensation of o-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O with glycerol leads to the production of a series of esters, with, in presence of excess of glycerol, condensation between OH-groups; in the latter case the mol. wt. rises more rapidly with time of heating than in the former.

R. T.

**Derivatives of tert.-alcohols. Hydrogen phthalates.** W. A. FESSLER and R. J. SHRINER (J. Amer. Chem. Soc., 1936, 58, 1384—1386).—CR<sub>3</sub>·O·MgBr and o-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O (I) or its derivatives in Et<sub>2</sub>O-dioxan at 0—55° give 36—66% of the CR<sub>3</sub>H phthalate. The following are described: Bu<sup>n</sup>H

phthalate, m.p. 85.5—86.5°, 3-nitrophthalate, decomp. 145°, and tetrabromophthalate, decomp. 147°; Bu<sup>i</sup>, decomp. 142°, tert.-amyl, decomp. 126°, CEt<sub>3</sub>, decomp. 145°, CPr<sup>n</sup><sub>3</sub>, decomp. 138°, CBu<sup>n</sup><sub>3</sub>, decomp. 112°, and tri-n-amylcarbinyl, decomp. 102°, H tetra-chlorophthalates. o-CO<sub>2</sub>H·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>CHPh<sub>2</sub> is obtained in 74% yield from CHPh<sub>2</sub>·O·MgBr and (I); CHPh<sub>2</sub>·OH and (I) at 110° give 18%. OBu<sup>n</sup>·MgBr (+0.5Et<sub>2</sub>O) is isolable from Bu<sup>n</sup>OH and MgEtBr in Et<sub>2</sub>O. H. B.

**2:4-Dinitrophenylhydrazides.** J. CEREZO and E. OLAY (Anal. Fis. Quím., 1934, 32, 1090—1099).—2:4-Dinitrophenylhydrazine heated with org. acids and 5N-H<sub>2</sub>SO<sub>4</sub> gives 2:4-dinitrohydrazides; those of the following acids are new: formic, m.p. 183—184° (decomp.); CH<sub>2</sub>Cl·CO<sub>2</sub>H, m.p. 199—200°; CH<sub>2</sub>Ph·CO<sub>2</sub>H, m.p. 177° (decomp.); CH<sub>2</sub>Ph·CH<sub>2</sub>·CO<sub>2</sub>H, m.p. 196—197°; stearic, from stearyl chloride, m.p. 120° (softens 116°). The derivatives of dibasic acids are of three types, normal monohydrazides [A], bishydrazides [B], and cyclic monohydrazides,

R<CO>N·NH·C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub> [C]. Derivatives of the following are described: malonic acid, type [A], m.p. 185—186° (decomp. to give the corresponding aceto-derivative); succinic, type [C], m.p. 269—270° (decomp.), also from the aceto-hydrazide and succinic acid; glutaric, type [B], m.p. 253—254°; phthalic, type [C], m.p. 268—269° (decomp.), also from the aceto-hydrazide and phthalic acid, converted by successive treatment with N-NaOH and N-HCl into type [A], which reverts to type [C] at 120—130°; 3-nitrophthalic, type [C], m.p. 249—250°; 3:6-dihydroxyphthalic, type [A], m.p. 277—278°, giving type [C] at 150°; phthalamic, from phthalimide, m.p. 298—299°. Derivatives could not be obtained from lactic, p-toluic, salicylic, cinnamic, iso- and terephthalic, tartaric, citric, and camphoric acids.

F. R. G.

**Improvement in the synthesis of hydroxycinnamic acids.** F. VORSATZ (J. pr. Chem., 1936, [ii], 145, 265—269).—The Knoevenagel synthesis of hydroxycinnamic acids from the appropriate hydroxy-aldehyde, CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub>, C<sub>6</sub>H<sub>5</sub>N, and a little C<sub>5</sub>H<sub>11</sub>N (or better, in some cases, NH<sub>2</sub>Ph) gives yields up to > 80%, provided the temp. does not exceed 80° for mono- and 60° for di-hydroxycinnamic acids. Daphnetin-3-carboxylic acid, prepared in this way (temp. 37°), had m.p. 272° (cf. A., 1934, 79). H. G. M.

**Preparation of some esters. II. F. ADICKES** (J. pr. Chem., 1936, [ii], 145, 235—242; cf. A., 1931, 822).—The prep. of the following is described: [C(CO<sub>2</sub>Et)<sub>2</sub>]<sub>2</sub>, Et fluorene-9-carboxylate, HCO<sub>2</sub>Pr, o-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>CH<sub>2</sub>Ph)<sub>2</sub>, Et<sub>2</sub> α-diphenylethylene-ββ-di-carboxylate, m.p. 71—72°, b.p. 175°/high vac. [from CPh<sub>2</sub>Cl<sub>2</sub> or CPh<sub>2</sub>Br<sub>2</sub>, b.p. 170—180°/13 mm. (cf. lit.), and Na (or, better, Mg) derivative of CH<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub>], hydrolysed by MeOH-KOH to the acid, m.p. 194—195°, Me<sub>3</sub> phenylmethanetricarboxylate, m.p. 84.5°, b.p. 141—142°/0.9 mm., and p-tolyl-9-fluorenylsulphone, m.p. 224—225°. An improved prep. of 9-bromofluorene from fluorene through Et 9-bromofluorene-9-glyoxylate is described. H. G. M.

**Unsaturated aralkyl ketones. III. Polymorphism of ethyl p-methoxycinnamoylpyruv-**

ate. E. FRIEDMANN (J. pr. Chem., 1936, [ii], 145, 341—352; cf. this vol., 1254).—*Et p-methoxycinnamoylpyruvate*, prepared from  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{CH}\cdot\text{COMe}$ ,  $\text{Et}_2\text{C}_2\text{O}_4$ , and  $\text{NaOEt}$ , exists in polymorphic forms, m.p.  $93^\circ$  (stable) and  $89^\circ$ , respectively, which differ slightly in colour and adsorption and in that hydrogenation of the former is slightly faster. Both forms give the same acid when hydrolysed. The stable form absorbs 6.27 and the unstable 5.68 mols. of  $\text{H}_2$  in 30 hr., but the reason for this excess is not evident.

R. S. C.

**1:4-Bridging of diethyl succinosuccinate.** P. C. GUHA (Current Sci., 1936, 5, 19—20).—The Na derivative of  $\text{Et}_2$  succinosuccinate and  $(\text{CH}_2\text{Br})_2$  yield the  $\text{Et}_2$  ester (I), m.p.  $112^\circ$ , of 1:4-endoethylene-cyclohexa-2:5-dione-1:4-dicarboxylic acid, m.p.  $274^\circ$ . With  $\text{KOH}\cdot\text{MeOH}$ , (I) gives *hexane- $\alpha\beta\epsilon\zeta$ -tetracarboxylic acid*, m.p.  $170^\circ$ , and with neutral  $\text{KMnO}_4$ , an acid, m.p.  $150^\circ$ . Using  $\text{CH}_2(\text{CH}_2\text{Br})_2$ , the  $\text{Et}_2$  ester, m.p.  $132^\circ$  of 1:4-endotrimethylenecyclohexa-2:5-dione-1:4-dicarboxylic acid, m.p.  $238^\circ$ , is similarly prepared. The *disemicarbazones* of the esters and acids are prepared.

E. W. W.

**Diveratrylacetic acid and triveratrylmethane.** P. DREYFUSS and F. SERRA (Rend. Semin. Fac. Sci. R. Univ. Cagliari, 1934, 4, 139—142; Chem. Zentr., 1935, ii, 3650).—3:4-Dimethoxymandelonitrile with veratrole and  $\text{H}_2\text{SO}_4$  yields *diveratrylacetoneitrile*, m.p.  $147^\circ$ , hydrolysed ( $\text{KOH}\cdot\text{EtOH}$ ) to *diveratrylacetic acid*, m.p.  $114^\circ$ . Condensation ( $\text{H}_2\text{SO}_4\text{-AcOH}$ ) of veratrole and veratraldehyde affords *triveratrylmethane*, m.p.  $142.5^\circ$ .

H. N. R.

**Oxidation of bisphenylpyruvic [ $\alpha$ -hydroxy- $\gamma$ -keto- $\beta$ -phenyl- $\alpha$ -benzylglutaric] acid.** J. JARROUSE (Compt. rend., 1936, 203, 259—261).—Oxidation of bisphenylpyruvic acid with  $\text{KMnO}_4$  in  $\text{NaOH}$  affords  $\alpha$ -hydroxydibenzyl ketone (I), m.p.  $114^\circ$  (cf. A., 1934, 523) (erroneously described as an aldehyde; cf. this vol., 73), and  $\text{H}_2\text{C}_2\text{O}_4$ . Ph  $\alpha$ -hydroxy- $\beta$ -phenylethyl ketone (J.C.S., 1914, 105, 1589) with dil.  $\text{NaOH}$  affords (I), and when oxidised gives  $\text{CH}_2\text{Ph}\cdot\text{COBz}$ , as does (I).

J. L. D.

**Toad poisons. IX. Questions of constitution.** H. WIELAND, G. HESSE, and R. HUTTEL [in part with H. BEHRINGER] (Annalen, 1936, 524, 203—222; cf. A., 1935, 749).—A new, mainly chromatographic, method of isolating bufotalin (I) and the subsidiary poisons from the dried secretion is described. The absorption spectrum of (I) indicates the presence of three, mutually conjugated double linkings as expressed by (I). This view harmonises with the production of  $\text{CHO}\cdot\text{CO}_2\text{H}$  by the ozonolysis of acetylbufotalin and the almost complete identity of the absorption spectra of (I) and scillariden A (II) for which Stoll has established the same skeleton.

Further, (I) and (II) appear to suffer similar fission by  $\text{KOH}\cdot\text{MeOH}$  and in the case of bufotalinin (III) the

corresponding *Me* ester, m.p.  $210\text{--}211^\circ$ , of the enolcarboxylic acid is obtained cryst. The presence of *tert.* OH at  $\text{C}_{14}$ , is rendered probable by the results of the alkaline fission of bufotalone and the analogy of the reaction with those of strophanthidin and scillaren. The *sec.* OH at  $\text{C}_{13}$  is not established with certainty but is placed there in analogy with the bile acids and sterols. The ready hydrolysis of (I) by cold  $\text{HCl}$  and the optical behaviour of bufotaliene indicates  $\text{OAc}$  attached to  $\text{C}_9$ . Bufotoxin has the same absorption spectrum as (I) and hence the same arrangement of double linkings. The increment of 1  $\text{H}_2\text{O}$  in it is due to firmly bound  $\text{H}_2\text{O}$  of crystallisation. It has therefore the structure (I) or (Ia) and the OH at  $\text{C}_{14}$  is esterified by the residue of suberylarginine. The absorption spectrum of bufotalidin (IV) shows the presence of the same, doubly-unsaturated lactone group as in (I) which is opened by  $\text{KOH}\cdot\text{MeOH}$  with formation of the *Me* ester, m.p.  $237^\circ$ , of the enolcarboxylic acid. When catalytically hydrogenated it absorbs 3  $\text{H}_2$  and yields a saturated acid. It does not contain  $\text{OMe}$  or  $\text{OAc}$ , and has  $[\alpha]_D +0.78^\circ$  in 80%  $\text{EtOH}$ ; it contains 1 OH and one double linking more than (I), but their location remains undecided. The separation of (III) from (IV) is difficult on account of its instability and the great firmness with which it retains solvent of crystallisation. (III) has the composition  $\text{C}_{24}\text{H}_{30}\text{O}_6$ , is without definite m.p., and has  $[\alpha]_D +14.14^\circ$  in 80%  $\text{EtOH}$ . It does not contain  $\text{OAc}$ . The *Ac* derivative has m.p.  $247^\circ$ . The ultra-violet absorption spectrum shows it to contain the same absorbing groups as (I) and (IV). The presence of two active H at  $28^\circ$  and of three at  $95^\circ$  in (III) is indicated. Since a stepwise action of (III) towards  $\text{MgMeI}$  is also observed it appears that two *sec.* OH and one *tert.* OH groups are present whereas the nature of the fourth O is undetermined. It absorbs  $>4 \text{ H}_2$  and therefore contains four double linkings or three double linkings and CO. The absorption spectra of gamabufogenin and arenobufogenin resemble those of (I), (III), and (IV) so that they belong to the same structural type.

H. W.

**Constituents of "senso." V. Constitution of  $\psi$ -bufotalin.** S. IKAWA (J. Pharm. Soc. Japan, 1935, 55, 748—757).—Deacetyltetrahydromethyl- $\psi$ -bufotalonic acid (*Me*<sub>1</sub> ester, m.p.  $95\text{--}97^\circ$ ) is ozonised to deacetyltetrahydromethyl- $\psi$ -bufotalonic peroxide and deacetyltetrahydromethyl- $\psi$ -bufotalonolactone,  $\text{C}_{19}\text{H}_{28}\text{O}_5$  (diacetate, m.p.  $111\text{--}113^\circ$ ; *Et*<sub>2</sub> acetal, m.p.  $91\text{--}92^\circ$ ). Ozonolysis of *Me* deacetyltetrahydro- $\psi$ -bufotalinate (I) yields a *keto-aldehyde*,  $\text{C}_{20}\text{H}_{30}\text{O}_8$ , m.p.  $114\text{--}116^\circ$ , and a *ketonic acid*,  $\text{C}_{23}\text{H}_{33}\text{O}_6\cdot\text{CO}_2\text{H}$ , which, when heated, yields a *dilactone*,  $\text{C}_{24}\text{H}_{32}\text{O}_7$ , decomp.

$172\text{--}174^\circ$  (oxime, m.p.  $180\text{--}181^\circ$ ). Se-dehydrogenation of (I) yields 3'-methyl-1:2-cyclopentenophen-

anthrene, m.p. 123—124°, the picrate of which is also obtained from the dehydrogenation product from  $\psi$ -bufotalin bromide. The appended structure is suggested for  $\psi$ -bufotalin.

CH. ABS. (r)

**Dihydroresorcinols.** III. Condensation of *p*-methoxystyryl methyl and ethyl ketone with ethyl ethane- $\alpha\alpha\beta$ -tricarboxylate. E. FRIEDMANN (J. pr. Chem., 1936, [ii], 146, 79—87).—Treatment of  $\text{CO}_2\text{Et}\cdot\text{CH}_2\cdot\text{CH}(\text{CO}_2\text{Et})_2$  with *p*-methoxystyryl Me ketone and  $\text{NaOEt}$  in  $\text{EtOH}$  at 115° yields *Et*<sub>2</sub> 2-*p*-anisylcyclohexane-4 : 6-dione-1-carboxylate-1-acetate, b.p. 243°/11 mm., m.p. 82.5°, which could not be hydrogenated ( $\text{Pd}-\text{BaSO}_4$  in  $\text{EtOH}$  at 20°). It is hydrolysed by aq.  $\text{NaOH}$  at room temp. to *Et* 1-carboxy-2-*p*-anisylcyclohexane-4 : 6-dione-1-acetate, m.p. 134°, decarboxylated at 140—160° to *Et* 2-*p*-anisylcyclohexane-4 : 6-dione-1-acetate, m.p. 71—72°, which probably exists in two cryst. forms. Similarly, *p*-methoxystyryl *Et* ketone affords *Et*<sub>2</sub> 2-*p*-anisyl-5-methylcyclohexane-4 : 6-dione-1-carboxylate-1-acetate, b.p. 243—245°/11 mm., whence *Et* 1-carboxy-2-*p*-anisyl-5-methylcyclohexane-4 : 6-dione-1-acetate, m.p. 127° (decomp.), and *Et* 2-*p*-anisyl-5-methylcyclohexane-4 : 6-dione-1-acetate, m.p. (indef.) 59—62°, apparently a mixture of isomerides. H. W.

Comparison of the action of the Grignard reagent on thiodiazolines and thioacylhydrazines. H. WUYTS and (Mlle.) A. LACOURT (Bull. Soc. chim. Belg., 1936, 45, 445—453; cf. A., 1933, 498, 831; 1935, 1360).—Thiodiazolines are unchanged in dry  $\text{Et}_2\text{O}$  by  $\text{MgMeI}$  or  $\text{MgEtBr}$  in excess at room temp. if the 2 position is unsubstituted. Benzaldehyde- $\beta$ -thiobenzoyl-, *o*-tolualdehyde- $\beta$ -*o*-toluoyl-, and *p*-tolualdehyde- $\beta$ -*p*-toluoyl- $\beta$ -methylhydrazones (I) with  $\text{MgMeI}$ ,  $\text{MgMeI}$ , and  $\text{MgEtBr}$ , respectively, in dry  $\text{Et}_2\text{O}$  at room temp., followed by hydrolysis, afford oily products (+ $\text{HgCl}_2$ , m.p. 99°, 83°, and 195°, respectively) which contain 1 labile H as well as S. (I) with  $\text{MgMeI}$  gives a compound, m.p. 98° (+ $\text{HgCl}_2$ , m.p. 87°), which does not react with  $\text{Ac}_2\text{O}$  or  $\text{BzCl}$ . Analysis indicates that in each case two alkyl groups have been introduced into the mol. Benzaldehydephenylmethylhydrazone is unaffected by  $\text{MgMeI}$  in boiling  $\text{Pr}_2\text{O}$ , whereas benzaldehydephenylhydrazone affords  $\text{NH}_2\text{Ph}$  and  $\text{COPhMe}$ .  $\alpha$ -Naphthaldehydephenylmethylhydrazone is unaffected by  $\text{MgMeI}$  in boiling  $\text{Pr}_2\text{O}$ .

J. L. D.

**Polyatomic co-ordinate valency rings with meta- and para-condensation.** P. PFEIFFER and H. PFITZNER (J. pr. Chem., 1936, [ii], 145, 243—256; cf. A., 1933, 824).—The Schiff's bases (apparently new; m.p. in parentheses) of  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  with the following diamines form co-ordinated Cu compounds by reaction with  $\text{Cu}(\text{OAc})_2$ : *o*- (164°), *m*- (109—110°), and *p*- (212°)  $\cdot\text{C}_6\text{H}_4(\text{NH}_2)_2$ ; 2-hydroxy- (162—163°), 1-methoxy- (165°) 3 : 5-phenylenediamine; 1 : 4- (141°), 1 : 5- (219—220°), and 2 : 7- (202°) naphthylenediamine; 3 : 3'-dimethyl- (202°) and 3 : 3'-dimethoxy- (162°) 4 : 4'-diaminodiphenylhydrazine (213°); 2 : 4-toluylenediamine (109°); 1 : 4'- (136°) and 4 : 4'- (256°) diaminodiphenyl. The properties of the complex with the last of these bases depends on the mode of prep. Resorcyalde-

hyde,  $\text{Ni}(\text{OAc})_2$ , and 3 : 5-diaminobenzoic acid give a Ni complex of the appropriate Schiff's base, and a Ni complex from the second of the above Schiff's bases is described. Most of these complexes are new (cf. *loc. cit.*). Mol. wt. determinations (b.p. elevation of  $\text{CHCl}_3$  or f.p. depression of  $\beta$ -naphthaquinoline or acridine; mol. f.p. depression const. 12.4° and 12.0°, respectively) on suitable

complexes show that only the *o*-diamine complexes have the simple unimol. structure (as inset), whilst those of the *m*-phenylene and benzidine series have a bi-

mol. structure with two metallic atoms. This accords with stereochemical requirements. H. G. M.

Reactions of aldoxime derivatives with bases. III. Reactions of geometrically isomeric acetyl-3 : 4-methylenedioxybenzaloximes with amines. C. R. HAUSER and E. JORDAN (J. Amer. Chem. Soc., 1936, 58, 1419—1422; cf. this vol., 332).—Acetyl- $\alpha$ -3 : 4-methylenedioxybenzaloxime with  $\text{NH}_2\text{Bu}^a$ ,  $\text{NH}_2\text{Ph}$ ,  $\text{NH}_2\text{Et}$ , or piperidine gives an almost quant. yield of the  $\alpha$ -oxime;  $\text{C}_5\text{H}_5\text{N}$  and  $\text{NEt}_3$  have little or no effect. Acetyl- $\beta$ -3 : 4-methylenedioxybenzaloxime with  $\text{NH}_2\text{R}$  and  $\text{NHR}_2$  affords the  $\beta$ -oxime (practically the sole product with weak bases and at <0° with strong bases) and/or 3 : 4-methylenedioxybenzonitrile (which is the sole product with  $\text{NR}_3$ ); analogous results are obtained with aq. solutions of the amines. H. B.

**Ketimine dyes and related compounds.** J. D. REID and D. F. J. LYNCH (J. Amer. Chem. Soc., 1936, 58, 1430—1432; cf. A., 1933, 826).—4 : 4'-*Di-n-butyl*-, m.p. 45° (all m.p. are corr.), 4 : 4'-*tetra-n-propyl*-, b.p. 260°/7 mm. [*dipicrate*, decomp. 175° (sinters at 165°)], and 4 : 4'-*tetra-n-butyl*-, b.p. 270—280°/6 mm. (*dipicrate*, m.p. 156°), -diaminodiphenylmethane are prepared from 40%  $\text{CH}_2\text{O}$  and  $\text{NHPhBu}^a$ ,  $\text{NPhPr}^a$ , and  $\text{NPhBu}^a$ , respectively, in dil.  $\text{HCl}$  at 90°. *p*-*Di-n-propylaminobenzoic acid*, m.p. 142°, is obtained from  $\text{NPhPr}^a$  and  $\text{COCl}_2$ . 4-*Di-n-propylaminobenzophenone*, m.p. 100°, is prepared from  $\text{NPhPr}^a$ ,  $\text{NHBzPh}$ , and  $\text{POCl}_3$  at <200°; the 4- $\text{NBu}^a$ -derivative could not be similarly obtained. *p*- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{COPh}$  (I),  $\text{NH}_2\text{Ph}$ , and  $\text{NH}_2\text{Ph}\cdot\text{HCl}$  at 160—180° give 4-aminobenzophenoneanil, m.p. 154° [*hydrochloride* (II), m.p. >400° (sinters about 275—280°)]. Repeated treatment of (II) in  $\text{EtOH}$  with gaseous  $\text{NH}_3$  affords a little 4-aminobenzophenoneimine (3 : 5-dinitrobenzoate, m.p. 198°), better obtained from (I) and  $\text{PCl}_5$  in  $\text{PhMe}$  followed by liquid  $\text{NH}_3$ . 4-Dimethyl- and 4-diethylaminobenzophenoneimine (3 : 5-dinitrobenzoates, m.p. 214° and 141°, respectively) are similarly formed from *p*- $\text{NAlk}\cdot\text{C}_6\text{H}_4\cdot\text{COPh}$ ,  $\text{POCl}_3$  (not  $\text{PCl}_5$ ), and  $\text{NH}_3$  in  $\text{PhMe}$ . The *Bz* derivative, m.p. 165°, of 4 : 4'-tetraethylaminobenzophenoneimine, prepared using  $\text{Bz}_2\text{O}$  in  $\text{C}_6\text{H}_6$ , is an indicator (yellow  $\rightarrow$  blue;  $p_H$  4—5.2). The 3 : 5-dinitrobenzoates of  $\text{NPhEt}_2$ ,  $\text{NPhPr}^a$ ,  $\text{NPhBu}^a$ , and  $\text{NHPbBu}^a$  have m.p. 120°, 118°, 104°, and 98.5°, respectively. H. B.

**Michael condensation.** IV. Active methylene group in sulphones. R. CONNOR, C. L. FLEMING,

jun., and T. CLAYTON (J. Amer. Chem. Soc., 1936, 58, 1386—1388).— $p$ -C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub>·CH<sub>2</sub>Ph (I) undergoes the Michael condensation; with CHPh·CH·COPh and MeOH—NaOMe in C<sub>6</sub>H<sub>6</sub>  $\alpha$ -benzoyl- $\gamma$ - $p$ -toluenesulphonyl- $\beta$ - $\gamma$ -diphenylpropane, stereoisomeric forms, m.p. 139—141° (corr.) and 197—197.5° (corr.), results. (I) thus resembles deoxybenzoin (II). (I) and (II) do not react with CHPh·CH·CO<sub>2</sub>Me. CH<sub>2</sub>(SO<sub>2</sub>Ph)<sub>2</sub>, but not (I), gives a positive HgCl<sub>2</sub> test (this vol., 1133); neither reacts with PhCHO,  $p$ -C<sub>6</sub>H<sub>4</sub>Cl·CHO, SeO<sub>2</sub>, HNO<sub>3</sub>, or isoamyl nitrite. H. B.

**Applications of the Rosenmund-von Braun nitrile synthesis.** C. F. KOELSCH (J. Amer. Chem. Soc., 1936, 58, 1328—1330).— $p$ -Iodobenzylidene-phthalide, m.p. 172—173° [from  $p$ -C<sub>6</sub>H<sub>4</sub>I·CH<sub>2</sub>·CO<sub>2</sub>H,  $o$ -C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>)<sub>2</sub>O, and a little NaOAc at 225—235°], is converted by MeOH—NaOMe into 2- $p$ -iodophenyl-1:3-indanedione, colourless and reddish-violet forms, both m.p. 145—146° (red melt), which with MgPhBr gives 3-phenyl-2- $p$ -iodophenylindone (I), m.p. 141—143°. (I) and CuCN at 240° (cf. von Braun and Manz, A., 1931, 1044) afford 3-phenyl-2- $p$ -cyanophenylindone, m.p. 142—144°.  $\alpha$ -Diphenyl- $\beta$ - $p$ -iodophenylpropan- $\beta$ -ol, m.p. 117—117.5° (from  $p$ -C<sub>6</sub>H<sub>4</sub>I·CO<sub>2</sub>Et and CH<sub>2</sub>Ph·MgCl), is dehydrated (AcOH—H<sub>2</sub>SO<sub>4</sub>) to the propylene, m.p. 92—92.5°, which with Br in boiling AcOH gives 1-phenyl-2- $p$ -iodophenylindene (II), m.p. 184—185°, and (probably)  $\alpha$ -bromo- $\alpha$ -diphenyl- $\beta$ - $p$ -iodophenylpropylene, m.p. 165—168° (decomp.). (II) and PhCHO in EtOH—NaOEt afford 3-phenyl-2- $p$ -iodophenyl-1-benzylideneindene, m.p. 173—174°, oxidised (CrO<sub>3</sub>, AcOH) to (I). 2-Phenyl-1:3-indanedione and  $p$ -C<sub>6</sub>H<sub>4</sub>Br·MgBr give 2-phenyl-3- $p$ -bromophenylindone, m.p. 172—174°, which with CuCN at 250° yields 2-phenyl-3- $p$ -cyanophenylindone, m.p. 184—187°. The mixture of phthalides from CH<sub>2</sub>Ph·CO<sub>2</sub>H, 4-bromophthalic anhydride, and a little NaOAc at 220—240° is converted by MeOH—NaOMe into 5-bromo-2-phenyl-1:3-indanedione, colourless and violet-black forms, both m.p. 166—167° (red melt), which with MgPhBr affords 5- (III), m.p. 167—168°, and 6- (IV), m.p. 192—194°, -bromo-2:3-diphenylindones. (III) is oxidised (CrO<sub>3</sub>, AcOH) to 4-bromo-2-benzoylbenzoic acid, whilst (IV) and CuCN at 250° give 6-cyano-2:3-diphenylindone, m.p. 209—211°.

Diphenyl- $p$ -bromobenzylcarbinol, m.p. 124—126° (from  $p$ -C<sub>6</sub>H<sub>4</sub>Br·CH<sub>2</sub>·MgBr and COPh<sub>2</sub>), is converted by Br in AcOH into  $\beta$ -diphenyl- $\alpha$ - $p$ -bromophenylvinyl bromide, m.p. 109—110°, which is resinified by CuCN at 240°. CPh<sub>2</sub>·CPh·CN is similarly obtained in quant. yield from CPh<sub>2</sub>·CPhBr, whilst  $\alpha$ -phenyl- $\beta$ -diphenyl-nevinyl bromide (A., 1932, 1024) affords  $\alpha$ -phenyl- $\beta$ -diphenyleneacrylonitrile, m.p. 188—189°. H. B.

**Halogen analogues of adrenaline and ephedrine.** III. Derivatives of propiophenone and general discussion. R. P. EDKINS and W. H. LINNELL (Quart. J. Pharm., 1936, 9, 203—229).—4-Hydroxypropiophenone, m.p. 149° (prepared by action of AlCl<sub>3</sub> on EtCO<sub>2</sub>Ph in CS<sub>2</sub>), is nitrated to the 3-NO<sub>2</sub>-derivative, m.p. 66°, reduced to the 3-NH<sub>2</sub>-compound (hydrochloride, m.p. 217°) in poor yield; this yields through the diazo-compounds 3-chloro-4-hydroxypropiophenone, m.p. 79° (Bz compound, m.p.

107.5°), which on nitrosation and reduction affords 3-chloro-4-hydroxy- $\alpha$ -aminopropiophenone hydrochloride, m.p. 138.6°. 4-Chloropropiophenone, m.p. 35.8° (4-Br-compound, m.p. 47°), prepared from PhCl and (EtCO)<sub>2</sub>O, with HCl and Bu nitrite yields 4-chloro-oximinopropiophenone, m.p. 114° (4-Br-compound, m.p. 133.6°), reduced (SnCl<sub>2</sub>—HCl) to 4-chloro- $\alpha$ -aminopropiophenone hydrochloride, m.p. 259° (4-Br-compound, m.p. 252°).  $\alpha$ -Aminopropiophenone hydrochloride, m.p. 187°, obtained from oximinopropiophenone, is hydrogenated to norephedrine. The stability of the aminoketones towards NaOH and EtOH—KOH has been determined and it is shown that there is no obvious relationship between the stabilities of the substances and their toxicity or pharmacological activity. F. R. S.

**Unsaturated aralkyl ketones.** I. Anisylidenemethyl methyl, [ethyl,] and  $n$ -propyl ketones. E. FRIEDMANN. II.  $o$ -Tolylidenebenzylidene- and di- $o$ -tolylidene-acetone. E. FRIEDMANN and W. E. VAN HEYNINGEN (J. pr. Chem., 1936, [iii], 145, 321—336, 337—340).—I.  $p$ -OMe·C<sub>6</sub>H<sub>4</sub>·CHO (I), when shaken with 10% NaOH and COMe<sub>2</sub>, COMeEt, or COMePr for 3, 16, or 11 days, respectively, gives about 50% yields of 4-methoxystyryl Me ketone (II), m.p. 73—74°, b.p. 176—177°/11 mm. (2:4-dinitrophenylhydrazones, m.p. 229°), 4-methoxystyryl Et (III), b.p. 180—181°/11 mm., m.p. 61° (oxime, +H<sub>2</sub>O, m.p. 105°; 2:4-dinitrophenylhydrazones, m.p. 200—201°), and  $Pr^a$  ketone (IV), b.p. 170—189°/11 mm., m.p. 40—41° (2:4-dinitrophenylhydrazones, m.p. 190°). Hydrogenation (Pd—BaSO<sub>4</sub>; EtOH) gives pure saturated ketones if continued until the reaction slows down, which occurs only after absorption of rather >2 H; cessation of reaction after absorption of exactly 2 H leaves some unsaturated ketone. Thus are prepared anisylacetone, b.p. 150—151°/9 mm. (2:4-dinitrophenylhydrazones, m.p. 145°, clears at 149—150°),  $\beta$ -anisylethyl Et (V), b.p. 160—162° (2:4-dinitrophenylhydrazones, m.p. 103—104°), and  $Pr^a$  ketone, b.p. 170—172°/9 mm. (2:4-dinitrophenylhydrazones, transparent at 104°, m.p. 112—114°). (I), CH<sub>3</sub>(CO<sub>2</sub>H)<sub>2</sub>, and piperidine in C<sub>5</sub>H<sub>5</sub>N give  $p$ -OMe·C<sub>6</sub>H<sub>4</sub>·CH·CH·CO<sub>2</sub>H (52% yield), m.p. 175°, clears at 192° (cf. lit.), reduced by Na—Hg to  $p$ -OMe·C<sub>6</sub>H<sub>4</sub>·[CH<sub>2</sub>]<sub>2</sub>·CO<sub>2</sub>H (74.1%), the Ca salt, +2H<sub>2</sub>O, of which with (EtCO<sub>2</sub>)<sub>2</sub>Ca at 305° gives a poor yield of (V). The relative rates of hydrogenation and solubilities in olive oil or mixtures thereof with OMe·CH<sub>2</sub>·CH<sub>2</sub>·OH are (II) > (III) > (IV). (II), (III), and (IV) spread well on H<sub>2</sub>O at  $p_H$  7.5, having a surface potential of about 400 mv. M.p. are corr.

II.  $o$ -OMe·C<sub>6</sub>H<sub>4</sub>·CHO and NaOH—aq. EtOH with CHPh·CH·COMe or COMe<sub>2</sub> give 2'-methoxy-2-methyldistyryl, m.p. 61—62°, and 2:2'-dimethyldistyryl ketone, m.p. 99°, respectively, which with 2:4-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·NH·NH<sub>2</sub> give pyrazoline derivatives, m.p. 193° and 202.5°, respectively. R. S. C.

**Phenyl mesityl diketone** [2:4:6-trimethylbenzil]. H. H. WEINSTOCK, jun., and R. C. FUSON (J. Amer. Chem. Soc., 1936, 58, 1233—1236).—2:4:6-Trimethylbenzil (I), m.p. 136—137° (oxime, m.p. 155°; 2:4-dinitrophenylhydrazones, m.p. 232—232.5°),

now prepared (cf. A., 1934, 525) by oxidation ( $\text{SeO}_2$ , dioxan, little  $\text{H}_2\text{O}$ ) of  $\text{C}_6\text{H}_2\text{Me}_3\cdot\text{CO}\cdot\text{CH}_2\text{Ph}$  (*p*-chlorobenzylidene derivative, m.p.  $141^\circ$ ), does not react with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  in EtOH or AcOH, is oxidised (30%  $\text{H}_2\text{O}_2$ , dioxan) to  $\text{BzOH}$  and  $s\text{-C}_6\text{H}_2\text{Me}_3\cdot\text{CO}_2\text{H}$ , and with  $\text{MgPhBr}$  gives 2:4:6-trimethylbenzoyl-diphenylcarbinol, m.p.  $169.5\text{--}170^\circ$ . (I) is reduced (Zn, AcOH) to 2:4:6-trimethylbenzoin (II) (designated 2':4':6'- in A., 1935, 1499),  $\text{C}_6\text{H}_2\text{Me}_3\cdot\text{CO}\cdot\text{CHPh}\cdot\text{OH}$ , m.p.  $101\text{--}102^\circ$  [phenylcarbamate, m.p.  $160\text{--}161^\circ$ ; attempted prep. of 2:4-dinitrophenylhydrazones gives that of (I)], and 2':4':6'-trimethylbenzoin (III),  $\text{C}_6\text{H}_2\text{Me}_3\cdot\text{CH}(\text{OH})\cdot\text{COPh}$ , m.p.  $93.5\text{--}94^\circ$  (phenylcarbamate, m.p.  $141\text{--}142^\circ$ ; 2:4-dinitrophenylhydrazone, m.p.  $211.5\text{--}212^\circ$ ); more vigorous reduction (Zn, AcOH) of (I)—(III) affords Ph 2:4:6-trimethylbenzyl ketone (IV), m.p.  $163.5\text{--}164^\circ$  (phenylhydrazone, m.p.  $104\text{--}105^\circ$ ; 2:4-dinitrophenylhydrazone, 2 forms, m.p.  $163^\circ$  and  $190^\circ$ ), also obtained by reduction of (I) with Zn+aq. EtOH-KOH or Sn+EtOH-conc. HCl and of (II) with Sn+HCl. (IV) is synthesised from  $s\text{-C}_6\text{H}_2\text{Me}_3\cdot\text{CH}_2\cdot\text{COCl}$ ,  $\text{C}_6\text{H}_6$ , and  $\text{AlCl}_3$ . Oxidation ( $\text{SeO}_2$ ) of (IV) gives (I), whilst treatment with an excess of  $\text{MgEtBr}$  or  $\text{MgPr}^n\text{Br}$  affords  $\beta\gamma$ -dihydroxy- $\beta\gamma$ -diphenyl- $\alpha\delta$ -dimesitylbutane, m.p.  $241\text{--}242^\circ$ . (I) is converted by aq. MeOH-KOH into phenylmesitylglycollic acid (+MeOH), m.p.  $87\text{--}89^\circ$ , (+EtOH), m.p.  $84\text{--}85^\circ$  (Me ester, m.p.  $111\text{--}111.5^\circ$ ), reduced (P, I or Zn, AcOH) to  $s\text{-C}_6\text{H}_2\text{Me}_3\cdot\text{CHPh}\cdot\text{CO}_2\text{H}$ .

H. B.

**1:2-Diketo-3-phenylhydrindene.** C. F. KOELSCH (J. Amer. Chem. Soc., 1936, 58, 1321—1324).—3-Phenylhydrindone,  $\text{BuO}\cdot\text{NO}$ , and conc. HCl in 95% EtOH give 2-oximino-3-phenylhydrindone, m.p.  $198\text{--}203^\circ$  (decomp.) (Me ether, m.p.  $148\text{--}149^\circ$ ), hydrolysed ( $\text{AcCO}_2\text{H}$ , AcOH, and aq. HCl) to the violet 1:2-diketo-3-phenylhydrindene (I), dimorphous, both m.p.  $140\text{--}147^\circ$  [quinoxaline, m.p.  $169\text{--}172^\circ$ , from  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ ], which is oxidised (3%  $\text{H}_2\text{O}_2$ , 0.5N-NaOH) to diphenylmethane- $\alpha\alpha$ -dicarboxylic acid, m.p.  $171\text{--}172^\circ$  (decomp.). (I) does not give a colour with  $\text{FeCl}_3$  [oxidation to a compound,  $\text{C}_{30}\text{H}_{18}\text{O}_4$ , m.p.  $200\text{--}205^\circ$  (decomp.) (darkens at  $180^\circ$ ), occurs], but it appears to exist completely in the enolic form (i.e., 2-hydroxy-3-phenylindone; not an *o*-quinonoid form). Methylation ( $\text{Me}_2\text{SO}_4$ , N-NaOH) of (I) thus gives the unstable 2-methoxy-3-phenylindone, m.p.  $67\text{--}68^\circ$  (oxime, m.p.  $184\text{--}186^\circ$ ), which is reduced (Zn dust, AcOH) to 2-methoxy-3-phenylhydrindone, m.p.  $96\text{--}98^\circ$ , whilst (I) and  $\text{MgPhBr}$  afford 1-hydroxy-2-keto-1:3-diphenylhydrindene, m.p.  $195\text{--}200^\circ$  (decomp.), which is oxidised ( $\text{CrO}_3$ , AcOH) to  $o\text{-C}_6\text{H}_4\text{Bz}$ , and is reduced (HI, AcOH) to 2-keto-1:3-diphenylhydrindene, m.p.  $169^\circ$  (decomp.). (I) and  $\text{CH}_2\text{Ph}\cdot\text{MgCl}$  give 1-hydroxy-2-keto-3-phenyl-1-benzylhydrindene, m.p.  $155\text{--}157^\circ$ . 3-Bromo-1:2-diketo-3-phenylhydrindene (II), m.p.  $77\text{--}79^\circ$  [from (I) and Br in  $\text{CCl}_4$ ], and MeOH lead to 2:2:3-trimethoxy-3-phenylhydrindone, m.p.  $102\text{--}103^\circ$ , hydrolysed ( $\text{AcOH}\text{--}\text{H}_2\text{SO}_4$ ) to 1:2-diketo-3-methoxy-3-phenylhydrindene, m.p.  $86\text{--}87^\circ$  [hydrate, m.p.  $115\text{--}120^\circ$  (loss of  $\text{H}_2\text{O}$ ); quinoxaline]. 2:2:3-Triethoxy-3-phenylhydrindone, m.p.  $89\text{--}90^\circ$  [from (II) and EtOH], is similarly hydrolysed to 1:2-diketo-3-ethoxy-3-phenylhydrindene, m.p.  $102\text{--}$

$103^\circ$ . Replacement of the enolisable H of (I) by OAlk thus activates the 2-CO. H. B.

**Attempted synthesis of compounds containing the isoindene nucleus.** C. F. KOELSCH (J. Amer. Chem. Soc., 1936, 58, 1331—1333).—Compounds containing the isoindene nucleus (A) could not be prepared. 2-Anisyl-1:3-indanedione, m.p.  $152\text{--}154^\circ$

(from phthalide and  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  in EtOH-NaOEt), and  $\text{MgPhBr}$  in PhMe give 3-phenyl-2-anisylindone (I), m.p.  $117\text{--}118^\circ$ , demethylated (40% HBr, AcOH) to 3-phenyl-2-p-hydroxyphenylindone, m.p.  $163\text{--}165^\circ$  (benzoate, m.p.  $145^\circ$ ), which with  $\text{MgPhBr}$  in  $\text{C}_6\text{H}_6$  affords 1-hydroxy-1:3-diphenyl-2-p-hydroxyphenylindene, m.p.  $196\text{--}197^\circ$ . This could not be dehydrated (heat; AcOH); AcOH- $\text{H}_2\text{SO}_4$  gives amorphous material. 3-Phenyl-2-p-cyanophenylindone is hydrolysed (dil.  $\text{H}_2\text{SO}_4$ ) to the 2-p-carbamyl, m.p.  $248\text{--}254^\circ$  (decomp.), and 2-p-carboxy-derivatives (II), m.p.  $212\text{--}214^\circ$ . The Me, m.p.  $167\text{--}168^\circ$ , and Et ester, m.p.  $120\text{--}121^\circ$ , of (II) or 3-phenyl-2-p-benzoylphenylindone, m.p.  $169\text{--}171^\circ$  [from the chloride of (II) and  $\text{AlCl}_3$  in  $\text{C}_6\text{H}_6$ ], with  $\text{MgPhBr}$  (excess) give 1-hydroxy-1:3-diphenyl-2-p- $\alpha$ -hydroxybenzylhydrindene. This and its  $\text{Me}_2$  ether (?) and chloride (?) with Zn and AcOH-conc. HCl afford 1:3-diphenyl-2-p-benzhydrilphenylindene, m.p.  $173\text{--}175^\circ$ , which is oxidised ( $\text{CrO}_3$ , AcOH) to  $o\text{-C}_6\text{H}_4\text{Bz}$  and  $p\text{-CO}_2\text{H}\cdot\text{C}_6\text{H}_4\cdot\text{CPh}\cdot\text{OH}$ .  $\alpha\gamma$ -Diphenyl- $\beta$ -anisylpropan- $\beta$ -ol, m.p.  $93\text{--}94^\circ$  (from Me anisate and  $\text{CH}_2\text{Ph}\cdot\text{MgCl}$ ), is dehydrated (AcOH- $\text{H}_2\text{SO}_4$ ) to the propylene, m.p.  $82\text{--}83^\circ$ , which is converted by Br in boiling AcOH into 1-phenyl-2-anisylindene, m.p.  $120\text{--}122^\circ$ . This and PhCHO with EtOH-NaOEt in  $\text{Pr}^n\text{OH}$  give 3-phenyl-2-anisyl-1-benzylideneindene, m.p.  $188\text{--}190^\circ$ , also obtained by dehydration (AcOH- $\text{H}_2\text{SO}_4$ ) of the carbinol from (I) and  $\text{CH}_2\text{Ph}\cdot\text{MgCl}$ . H. B.

**Derivatives of 1:3-diketohydrindene.** W. H. HUNTER and E. C. YACKEL (J. Amer. Chem. Soc., 1936, 58, 1395—1396).—2-Benzoyl-1:3-indanedione (I) is cleaved by Br in AcOH at  $100^\circ$  (bath) to  $\text{BzOH}$  and 2:2-dibromo-1:3-indanedione (II), m.p.  $178\text{--}179^\circ$ . (I) and  $\text{HNO}_3$  (d 1.5) in conc.  $\text{H}_2\text{SO}_4$  at  $-5^\circ$  give 2-m-nitrobenzoyl-1:3-indanedione, m.p.  $228\text{--}229^\circ$  (decomp.), which is similarly cleaved to (II) and  $m\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . The Na (III) and Ag (IV) derivatives of Et 1:3-indanedione-2-carboxylate with AcCl give the readily hydrolysable Et 3-acetoxyindone-2-carboxylate, m.p.  $77\text{--}78^\circ$ ; (IV) [not (III)] and  $\text{BzCl}$  in  $\text{C}_6\text{H}_6$  afford the 3-benzoyloxy-ester, m.p.  $146\text{--}148^\circ$  (Hantzsch and Gajewski, A., 1912, i, 870). (III) and  $\text{BzCl}$  alone at  $80^\circ$  give a compound,  $\text{C}_{14}\text{H}_{10}\text{O}_4$ , m.p.  $140\text{--}141^\circ$ . H. B.

**Diphenacylfluorene; its relationship to fluor-enylideneacetophenone.** C. DUFRAISSE and A. P. DE CARVALHO (Bull. Soc. chim., 1936, [v], 3, 882—884).—Fluorenone (I),  $\text{COPhMe}$  (II),  $\text{Et}_2\text{O}$ , and  $\text{NaNH}_2$  give 9:9-diphenacylfluorene (cf. this vol., 208) (dioxime, m.p.  $214\text{--}215^\circ$ ), which decomposes at  $230^\circ$  into (II) and  $\omega$ -fluorenylideneacetophenone (A., 1930, 1437), also obtained direct from (I), (II), EtOH, and HCl. H. G. M.

**Sterols. VI. Synthetic preparation of oestrone (theelin).** R. E. MARKER, O. KAMM, T. S. OAKWOOD, and J. F. LAUCIUS (J. Amer. Chem. Soc., 1936, 58, 1503—1504).—Dehydroncoergosterol is reduced (Na, amyl alcohol) to the phenolic *tetrahydrodehydroncoergosterol*, m.p. 170.5—171.5°; acetylation, oxidation ( $\text{CrO}_3$ ), and hydrolysis ( $\text{EtOH-NaOH}$ ) of the resultant neutral product gives oestrone, m.p. 259—261.5°,  $[\alpha]_D^{25} +159^\circ$  in  $\text{EtOH}$  [benzoate, m.p. 205—207°; semicarbazone ( $+0.5\text{H}_2\text{O}$ ), m.p. 252—253°]. H. B.

Possible methods of synthesis of the carbon skeleton present in sterols, bile acids, sexual hormones, and plant heart poisons. P. P. T. SAH (Sci. Rep. Nat. Tsing Hua Univ., 1936, 3, 317—343).—Six methods for the synthesis of the skeleton present in female sexual hormones and three methods for the male sexual hormones have been suggested.

F. R. S.

**Dihydroresorcinols. I. Hydrolysis of dihydroresorcinolcarboxylic esters. II. Autoxidation of dihydroresorcinol derivatives.** E. FRIEDMANN (J. pr. Chem., 1936, [ii], 146, 65—70, 71—78).—I. Dihydroresorcinolcarboxylic esters are readily hydrolysed by cold aq. alkali and subsequent decarboxylation of the acids gives the corresponding dihydroresorcinols in excellent yield. Thus Et 2-*p*-anisylcyclohexane-4 : 6-dione-1-carboxylate affords 1-*p*-anisylcyclohexane-3 : 5-dione, m.p. 181°, in 86—100% yield; it is reduced by Zn-Hg and boiling 5*N*-HCl to *p*-anisylcyclohexane, b.p. 141—144°/11 mm.  $\text{CHNa}(\text{CO}_2\text{Et})_2$  and *p*-methoxystyryl Et ketone afford Et 2-*p*-anisyl-5-methylcyclohexane-4 : 6-dione-1-carboxylate, m.p. 119—120°, hydrolysed and decarboxylated to 4-*p*-anisyl-1-methylcyclohexane-3 : 5-dione, m.p. 201—202°, whence 4-*p*-anisyl-1-methylcyclohexane, b.p. 156—159°/11 mm.

II. Condensation of *p*-methoxystyryl Me ketone with  $\text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$  and NaOEt in EtOH affords 1-cyano-2-*p*-anisylcyclohexane-4 : 6-dione (I), m.p. 207° (decomp.) after becoming red (Na derivative; corresponding *O*-Me ether, m.p. 171°). Similarly, *p*-methoxystyryl Et ketone affords 1-cyano-2-*p*-anisyl-5-methylcyclohexane-4 : 6-dione (II), m.p. 173° (*O*-Me ether, m.p. 195—196°). The presence of Me at  $\text{C}_5$  decreases the readiness of autoxidation and catalytic hydrogenation. H. W.

**Synthesis of 2 : 4-dihydroxybenzophenone.** R. C. SHAH and P. R. MEHTA (J. Indian Chem. Soc., 1936, 13, 368—371).— $\text{NHPhBz}$  and  $m\text{-C}_6\text{H}_4(\text{OH})_2$  (I) in presence of  $\text{ZnCl}_2$  and  $\text{POCl}_3$  at 130—140° afford a product which with boiling 2*N*-NaOH is converted into 2 : 4-dihydroxybenzophenone (II).  $\text{NH}_2\text{Bz}$  reacts similarly, but  $\text{PhCN}$  is a by-product. (I) with  $\text{BzOH}$  and  $\text{ZnCl}_2$ ,  $\text{SnCl}_4$ , or  $\text{P}_2\text{O}_5$  gives a poor yield of (II).

J. L. D.

**periNaphthindene [phenalene] series. I. Condensation of  $\beta$ -naphthol with cinnamic acid.** C. F. KOELSCH (J. Amer. Chem. Soc., 1936, 58, 1326—1328).— $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  and  $\beta\text{-C}_{10}\text{H}_7\cdot\text{OH}$  in boiling  $\text{AcOH-H}_2\text{SO}_4$  give 4-phenyl-3 : 4-dihydro-5 : 6-benzocoumarin, m.p. 115—116°, methylated ( $\text{Me}_2\text{SO}_4$ , 10% NaOH) to  $\beta$ -phenyl- $\beta$ -2-methoxy-1-naphthylprop-

ionic acid, m.p. 168—170°, the chloride of which with  $\text{AlCl}_3$  in  $\text{C}_6\text{H}_6$  affords 9-keto-6-methoxy-7-phenyl-7 : 8-dihydroperinaphthindene (I), m.p. 144—145° (oxime, m.p. 207—211°). (I) is demethylated (40% HBr, AcOH) to the 6-*OH*-derivative (II), m.p. 191—193° (sinters at 185°); oxidation ( $\text{CrO}_3$ , AcOH) gives 6a-hydroxy-6 : 9-diketo-7-phenyl-6 : 6a : 7 : 8-tetrahydroperinaphthindene ( $+ \text{H}_2\text{O}$ ), m.p. 105—110° (decomp.), m.p. (anhyd.) 160—163° (darkening), which is readily reduced (alkaline  $\text{Na}_2\text{S}_2\text{O}_4$ ) to (II). H. B.

**Tetramethoxyfluorene-carboxylic acid and the "red substance."** P. DREYFUSS (Rend. Semin. Fac. Sci. R. Univ. Cagliari, 1934, 4, 135—138; Chem. Zentr., 1935, ii, 3651—3652).—Condensation of veratrole with veratroylformic acid yields 2 : 3 : 6 : 7-tetramethoxyfluorene-9-carboxylic acid (monohydrate), which is decarboxylated to 2 : 3 : 6 : 7-tetramethoxyfluorene, oxidised to 2 : 3 : 6 : 7-tetramethoxyfluorenone (see below). H. N. R.

**2 : 3 : 6 : 7-Tetramethoxyphenanthraquinone.** A. OLIVERIO (Rend. Semin. Fac. Sci. R. Univ. Cagliari, 1934, 4, 126—129; Chem. Zentr., 1935, ii, 3651).—2 : 3 : 6 : 7-Tetramethoxyphenanthraquinone (improved prep.) [quinoxaline derivative, m.p. 270—271° (decomp.)] on distillation with CaO yields 2 : 3 : 6 : 7-tetramethoxyfluorenone, m.p. 202—208°, identical with the "red substance" of Vanzetti (A., 1927, 462). H. N. R.

**Synthesis of plumbagin.** J. SAENZ DE BURUAGA and F. VERDU (Anal. Fís. Quím., 1934, 32, 830—837; cf. A., 1933, 1053; Witanowski, A., 1935, 420, 1375; Feiser *et al.*, this vol., 728).—2-Methyl- $\alpha$ -naphthaquinone (A., 1930, 91) with  $\text{H}_2\text{SO}_5$  yields 5-hydroxy-2-methyl- $\alpha$ -naphthaquinone identical with plumbagin, together with, probably, the 3-*OH*-derivative, m.p. 164—167°. F. R. G.

**Constitution and reactivity. XVII. Action of hydrogen sulphates during sulphonation.** K. LAUER and Y. HINATA (J. pr. Chem., 1936, [ii], 145, 287—290; cf. this vol., 1239).—The velocity of sulphonation of anthraquinone by 89.5 and 95.8%  $\text{H}_2\text{SO}_4$  and 3.2% oleum with varying amounts of  $\text{KHSO}_4$  at 150—220° is measured.  $\text{KHSO}_4$  decreases the reaction velocity with conc. acid, but with more dil. acid the first additions cause an increase. Sulphonation is probably due to an unknown pyrosulphate and its hydrate. R. S. C.

**Introduction of side-chains into anthraquinones.** C. MARSCHALK, F. KENIG, and N. OUROUSOFF (Bull. Soc. chim., 1936, [v], 3, 1545—1575).—The leuco-compounds of aminoanthraquinones with  $\text{CH}_2\text{O}$  or, better,  $\text{OH}\cdot\text{CH}_2\cdot\text{SO}_3\text{Na}$  in alkaline  $\text{Na}_2\text{S}_2\text{O}_4$  in absence of  $\text{O}_2$  give sol. compounds with  $\text{CH}_2\cdot\text{SO}_3\text{Na}$  vicinal to the  $\text{NH}_2$ ; reduction by glucose or warm  $\text{Na}_2\text{S}_2\text{O}_4$  changes this substituent to Me and affords after re-oxidation aminomethylantraquinones (Me vicinal to  $\text{NH}_2$ ), which are usually the first products actually isolated. Hydroxyanthraquinones with aldehydes in hot alkaline  $\text{Na}_2\text{S}_2\text{O}_4$  in absence of  $\text{O}_2$  give *vic*-hydroxy-aryl- or -alkyl-anthraquinones (A). In some cases and under certain conditions  $\text{CH}_2\text{O}$  or

$\text{OH}\cdot\text{CH}_2\cdot\text{SO}_3\text{Na}$  gives  $\text{H}_2\text{O}$ -sol. salts,  $\text{R}\cdot\text{CH}_2\cdot\text{SO}_3\text{K}$  [e.g.,  $\text{K}_2$  anthrarufin-2 : 6-di(methylsulphonate)]; these are stable to  $\text{Na}_2\text{S}_2\text{O}_4$ , are converted into (A) only by fusion with alkali, and thus are not intermediates in the formation of the latter, in contrast to the amino-anthraquinone reaction. In the absence of  $\text{O}_2$  or of an excess of  $\text{Na}_2\text{S}_2\text{O}_4$  quinizarin and  $\text{CH}_2\text{O}$  give directly a little 2 : 3-dimethylquinizarin (I); in the complete absence of  $\text{Na}_2\text{S}_2\text{O}_4$  (and of air) much di-3-quinizarinylmethane, m.p. 296—297°, and a little 2-methylquinizarin (I), m.p. 178—179°, are obtained. The normal reaction of hydroxy-quinones is thus to form first the carbinols,  $\text{X}\cdot\text{CHR}\cdot\text{OH}$  ( $\text{R}$ =alkyl, aralkyl, or  $\text{H}$ ;  $\text{X}$ =leucohydroxyanthraquinonyl); the  $\text{CH}\cdot\text{OH}$  is then reduced to  $\text{Me}$  by the 9 : 10-( $\text{OH}$ )<sub>2</sub>; the resultant methylquinones are reduced again to the leuco-compounds by the excess of  $\text{Na}_2\text{S}_2\text{O}_4$  and are finally isolated as quinones only after re-oxidation.  $\text{CH}_2\text{O}$  is more reactive than are other aldehydes. Thus quinizarin gives the  $\text{Me}_2$  compound, but only the mono-Et or  $-\text{CH}_2\text{Ph}$  compounds; these latter products react further with  $\text{CH}_2\text{O}$  to give mixed alkyl derivatives. Similarly 2-hydroxyanthraquinone reacts with only one mol. of  $\text{PhCHO}$ , but with 2 of  $\text{CH}_2\text{O}$ . The quinones described below are prepared by the above-mentioned reactions. (I), m.p. 253° ( $\text{Ac}_2$  derivative). 1-Hydroxy-2-methyl- and -2-benzyl-, 1-amino-2-methyl-, m.p. 202°, 1 : 5-diamino-2 : 6-dimethyl- (III) [converted by diazo-reactions into 2 : 6-dimethylantraquinone or its 2 : 6-( $\text{OH}$ )<sub>2</sub>-derivative], 5-chloro-1-amino-2-methyl-, m.p. 213° (with  $\text{HNO}_3$  gives an indazole derivative), 8-chloro-1-amino-2-methyl-, and 1 : 8-diamino-2 : 7-dimethyl-anthraquinone (IV), m.p. 223° (block). (IV) is also obtained by nitration and subsequent reduction of 2 : 7-dimethylantraquinone, gives (diazo-reactions) the 1 : 8-( $\text{OH}$ )<sub>2</sub>-compound, m.p. 216—217° (cf. lit.), and 2 : 3-dimethylantraquinone (V), and, when treated with  $\text{S}_2\text{Cl}_2$ - $\text{PhNO}_2$  and then with  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$  and finally sulphonated gives a blue acid dye, as also does (II); when nitrated and then reduced it gives a substance dyeing cellulose acetate bluish-violet. 2-Ethyl-, m.p. 168—169° (oxidised by  $\text{H}_3\text{BO}_3$ - $\text{H}_2\text{SO}_4$ - $\text{HNO}_3$  at 140—143° to quinizarin-2-carboxylic acid), 2-methyl-3-ethyl-, m.p. 173—174° (oxidised to quinizarin-2 : 3-dicarboxylic acid), 2-butyl-, m.p. 125°, 2-benzyl-, m.p. 180—181° (very readily sulphonated), 2-benzyl-3-methyl-, m.p. 211°, 2-o-chlorobenzyl-, m.p. 183—184°, 2-p-tolylmethyl-, m.p. 177—178°, and 2-furfurylmethyl-quinizarin, m.p. 165—166°. 2 : 6-Dimethylanthrurufin, m.p. 240—241° ( $\text{Ac}_2$  derivative, m.p. 284—285°), also obtained (diazo-reaction) from (III). 2 : 7-Dimethylchrysazin, m.p. 216—217° ( $\text{Ac}_2$  derivative, m.p. 222—223°), also obtained from (IV). 1-Hydroxyanthraquinone-2-acetic acid (from  $\text{CHO}\cdot\text{CO}_2\text{H}$ ), m.p. 236—237° (block), when distilled, gives 1-hydroxy-2-methylantraquinone, affords 1-keto-5 : 6-phthaloyl-1 : 2-dihydrobenzofuran (VI) by treatment with  $\text{Ac}_2\text{O}$ , a substance,  $\text{C}_{16}\text{H}_{10}\text{O}_3$ , by the action of  $\text{SOCl}_2$ - $\text{PhNO}_2$  at 100° [also obtained similarly from (VI)], and by nitration and reduction a ? 4- $\text{NH}_2$ -derivative, which gives with  $\text{Al}(\text{OH})_3$  a violet lake, not fast to light. Quinizarin-2-acetic acid, m.p. 248—250°, gives similarly 2-methylquinizarin, with  $\text{H}_2\text{SO}_4$  an acid, which gives

a mordant dye, and with  $\text{H}_2\text{SO}_4$ - $\text{MnO}_2$  an orange acid; with  $\text{S}_2\text{Cl}_2$ - $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ - $\text{H}_2\text{SO}_4$  it gives a dye, as does (IV). 1-Hydroxy-2-o-carboxybenzyl-anthraquinone with  $\text{AlCl}_3$ - $\text{NaCl}$  at 150° gives impure 6-hydroxy-7 : 12 : 14-triketo-5 : 7 : 12 : 14-tetrahydro-

pentacene (VII). 2-o-Carboxybenzylquinizarin with  $\text{H}_2\text{SO}_4$ ,  $\text{ClSO}_3\text{H}$ , or  $\text{AlCl}_3$ - $\text{NaCl}$  at 140° gives 6 : 13-dihydroxy-7 : 12 : 14-triketo-5 : 7 : 12 : 14-tetrahydropentacene [cf. (VII)], oxidised by  $\text{MnO}_2$ - $\text{H}_2\text{SO}_4$  to 6 : 13-dihydroxypentacene-7 : 12 : 5 : 14-diquinone, also obtained from  $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$  and leucoquinizarin. 4-Chloro-1-aminoanthraquinone loses the  $\text{Cl}$  during reaction with  $\text{OH}\cdot\text{CH}_2\cdot\text{SO}_3\text{Na}$ - $\text{Na}_2\text{S}_2\text{O}_4$ . (V) and  $\text{HNO}_3$ - $\text{H}_2\text{SO}_4$  at  $-10^\circ$  give 1-nitro- and thence ( $\text{Na}_2\text{S}$ ) 1-amino-2 : 3-dimethyl-anthraquinone, m.p. 211°, which with oleum (2—3%  $\text{SO}_3$ )-paraformaldehyde- $\text{HNO}_3$  affords a  $\text{NO}_2$ -compound, reduced ( $\text{Na}_2\text{S}$ ) to 1 : 4-diamino-2 : 3-dimethyl-anthraquinone; with  $\text{MnO}_2$ - $\text{H}_2\text{SO}_4$  this gives (I), which is also obtained from 2-methylquinizarin (VIII) and  $\text{CH}_2\text{O}$ - $\text{Na}_2\text{S}_2\text{O}_4$ . 2 : 2'-Diquinizarin and  $\text{KOH}$ - $\text{Na}_2\text{S}_2\text{O}_4$ - $\text{CH}_2\text{O}$  at 95° give 3 : 3'-dimethyl-2 : 2'-diquinizarin, m.p.  $>320^\circ$ , reduced to (VIII) by  $\text{Na}_2\text{S}_2\text{O}_4$  in aq.  $\text{C}_6\text{H}_5\text{N}$  at 40—50°. The benzyl-anthraquinones mentioned are sulphonated by 98%  $\text{H}_2\text{SO}_4$  at room temp. or 100° to give dyes, which give bluish-red lakes with  $\text{Al}(\text{OH})_3$ . The quinizarin derivatives with  $\text{HCl}$ ,  $\text{H}_3\text{BO}_3$ ,  $\text{Zn}$  dust, and primary aromatic amines give 1-hydroxy-4-anilino-derivatives, which give dyes when sulphonated. Sulphonation of the carboxybenzyl and pentacene compounds leads to dehydration and often oxidation.

R. S. C.

**2-Deuterocamphane.** E. BILLMANN, K. A. JENSEN, and B. BAK (Ber., 1936, 69, [B], 1947—1949; cf. this vol., 855).—Further experiments show that the decomp. of  $\text{Mg}$  *l*-bornyl chloride (I) with  $\text{H}_2\text{O}$  gives dextrorotatory camphane preps. (II) which do not lose their optical activity when crystallised repeatedly. In contrast with earlier experiences, crude (II) are dextrorotatory instead of levorotatory, and the sign persists in spite of repeated crystallisation of the initial material. The production of (II) is hence a complex process, and the previous results are rendered uncertain. Parallel decomp. of (I) by  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$ , respectively, appear to yield identical products but the yields with  $\text{D}_2\text{O}$  are considerably  $<$  with  $\text{H}_2\text{O}$ .

**Chlorination of camphane.** A. GANDINI (Gazzetta, 1936, 66, 357—365).—Camphane (I) in  $\text{CHCl}_3$  treated in sunlight with 1  $\text{Cl}_2$  gives mainly bornyl chloride (II); (I) with 2  $\text{Cl}_2$ , or (II) in  $\text{CCl}_4$  with 1  $\text{Cl}_2$ , gives 2 : 3-dichlorocamphane (III), m.p. 126—126.5°, b.p.  $>220^\circ$  (decomp.) (of which a small amount is also obtained in the first reaction), oxidised by  $\text{KMnO}_4$  to *i*-camphoric acid, and to an acid, m.p. 100—101°. The structure of (III) is shown by its dechlorination ( $\text{Na}$  in  $\text{Et}_2\text{O}$ ) to bornylene, and its formation from the latter and  $\text{Cl}_2$ . E. W. W.

True constitution of camphenyl and 4-methylcamphenyl chloride and a stereois-

meric  $\alpha$ -fenchocamphorol. G. KOMPPA and G. A. NYMAN (Ber., 1936, 69, [B], 1813—1820).—The "camphenilyl chloride" (I) obtained from camphenilol (II) by the action of  $\text{PCl}_5$  in light petroleum is very resistant towards 0.5*N*-KOH-EtOH at 20°, so that Cl is completely *sec*. The substance A cannot

therefore be an intermediate in the transformation of (I) into santene. Hydrolysis of (I) with milk of lime at 50—60° gives a mixture of (II),  $\beta$ -fenchocamphorol, and  $\alpha$ -isofenchocamphorol (III), m.p. 132—133° (phenylurethane, m.p. 115—116°), oxidised to apocamphoric (IV) and apofenchocamphoric (V) acid and camphenilone. (I) is not therefore a normal derivative of (II), but is formed by change in the C skeleton, and consists mainly of apobornyl chloride. apocyclene hydrochloride is hydrolysed to a mixture of alcohols oxidised to (IV) and (V) and from which (III) is isolated by crystallisation. The non-identity of (III) and the  $\alpha$ -fenchocamphorol obtained by alkaline reduction of the corresponding ketone is established by the non-identity of the corresponding *H* phthalates, m.p. 168—169° and 166.5—167.5°, respectively, which show depression in mixed m.p. 4-Methylcamphenilol is similarly converted into the "chloride," which with milk of lime gives a (?) hydrocarbon and, mainly, *dl*-epiborneol, m.p. 179—181° (phenylurethane, m.p. 94—95°), oxidised to *dl*-camphoric acid. H. W.

**Physical identity of enantiomers. II. (a) Rotatory dispersion of *d*-, *l*-, and *dl*-oximinocamphor and their sodium derivatives. (b) Differences in the physiological action of *d*-, *l*-, and *dl*-forms of sodio-oximinocamphor.** B. K. SINGH and S. PRASAD (Proc. Indian Acad. Sci., 1936, 3, A, 586—593).—1-Oximinocamphor is obtained in the stable form, m.p. 152°, and unstable form, m.p. 114°, by the action of  $\text{C}_6\text{H}_{11}\text{ONO}$  on Na and *l*-camphor at 0°. The *dl*-compound, m.p. 108°, is similarly obtained from *dl*-camphor. The rotatory dispersions of *d*- and *l*-oximinocamphor in  $\text{C}_6\text{H}_6$ , EtOH, and  $\text{CHCl}_3$  and of their Na derivatives in  $\text{H}_2\text{O}$  are recorded, as are the physiological activities of *d*-, *l*-, and *dl*-sodio-oximinocamphor. F. N. W.

**Different reaction velocities of enantiomers with a common optically active reagent. I. New reactions of *d*- and *l*-camphor-10-sulphonyl chlorides.** A. S. GALLOWAY and J. READ (J.C.S., 1936, 1219—1222).—*d*-Camphor-10-sulphonyl chloride (I) and *p*-aminoacetanilide give the *Ac* derivative, m.p. 136—137°,  $[\alpha]_D +40.5^\circ$  in  $\text{CHCl}_3$ , hydrolysed to mono-*d*-camphor-10-sulphonyl-*p*-phenylenediamine (II), m.p. 185°,  $[\alpha]_D +41.1^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ . *p*-Acetamidophenyl *d*-camphor-10-sulphonate, m.p. 79°,  $[\alpha]_D +34.1^\circ$  in  $\text{CHCl}_3$ , is similarly obtained and is hydrolysed to the *p*-aminophenyl compound (III) m.p. 102—103°,  $[\alpha]_D +42.3^\circ$  in  $\text{CHCl}_3$ . (I) and (II) form *di*-*d*-, m.p. 188°,  $[\alpha]_D +52.3^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ , and *d*-camphor-10-sulphonyl-*p*-phenylenediamine, m.p. 206°,  $[\alpha]_D \pm 0.0^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ ; in this reaction, the proportion of *D*-*d* and *L*-*d* forms from the *d*- and *l*-forms of (I) is 58 : 42. *d*- and *l*-forms of (I) react with (III) to give *p*-*d*-, m.p. 133°,  $[\alpha]_D +69.9^\circ$  in  $\text{CHCl}_3$  and *p*-*l*-camphor-10-sulphonamidophenyl *d*-camphor-10-sul-

*phonate*, m.p. 135°,  $[\alpha]_D -2.4^\circ$  in  $\text{CHCl}_3$ , in the proportion 61 : 39. F. R. S.

**Homologues of the camphor group. X. Benzyldenecamphane, a dehydration product of *tert*-benzylbornyl alcohol.** S. S. NAMETKIN and M. K. STRUGATSKI (J. Gen. Chem. Russ., 1936, 6, 862—867).—*tert*-Benzylbornyl alcohol and anhyd.  $\text{KHSO}_4$  (150—160° : 3 hr.) yield benzyldenecamphane, m.p. 25° [wrongly identified by Haller *et al.* (A., 1906, i, 440) as  $\beta$ -benzylcamphene], also obtained synthetically from phenylbornylcarbinol by heating with K in PhMe, and treating the alkoxide so formed with  $\text{CS}_2$ , adding MeI to the ppt. of xanthate obtained, and decomp. the Me ester at 160°. R. T.

**New methods in stereochemistry. III. New optically active reagents for ketones and aldehydes.** A. S. GALLOWAY and J. READ (J.C.S., 1936, 1222—1225).—*p*-Hydroxynitrosomethylaniline and *d*-camphor-10-sulphonyl chloride give *p*-*d*-camphor-10-sulphonoxy-nitrosomethylaniline, m.p. 115°,  $[\alpha]_D +40.0^\circ$ , hydrolysed to the -methylaniline, m.p. 67—68°,  $[\alpha]_D +44.5^\circ$ , and reduced (Zn-AcOH) to the -phenyl- $\alpha$ -methylhydrazine, m.p. 45—46° (benzylidene, m.p. 138°, and *p*-nitrobenzylidene derivatives, m.p. 200°). *l*-Menthylamine and *p*- $\text{C}_6\text{H}_4\text{MeSO}_2\text{Cl}$  yield *p*-toluenesulphonbenzyl-*l*-menthylamide, m.p. 96—97°,  $[\alpha]_D -39.9^\circ$ , which with  $\text{HNO}_2$  gives benzyl-*l*-menthyl-nitrosoamine, m.p. 52°,  $[\alpha]_D -2.5^\circ$ . *p*-Nitrobenzyl-*l*-menthylamine, m.p. 53°,  $[\alpha]_D -89.4^\circ$  (*p*-toluenesulphonyl derivative, m.p. 115°,  $[\alpha]_D -49.3^\circ$ ), with AcOH and  $\text{NaNO}_2$  forms *p*-nitrobenzyl-*l*-menthyl-nitrosoamine, m.p. 132°,  $[\alpha]_D +17.6^\circ$ , reduced (Zn-AcOH) to the *p*-*NH*<sub>2</sub>-compound, m.p. 88°,  $[\alpha]_D +21.8^\circ$ . Et *l*-menthylglycine and  $\text{N}_2\text{H}_4$  yield *l*-menthylglycine-hydrazide,  $[\alpha]_D -57.7^\circ$ , which gives acetone-, m.p. 55°,  $[\alpha]_D -52.5^\circ$ , and *l*-menthone-*l*-menthylglycine-hydrazone,  $[\alpha]_D -69.1^\circ$ , and the benzylidene derivative of benzaldehyde-*l*-menthylglycinehydrazone, m.p. 158°,  $[\alpha]_D -266.9^\circ$ . Et *d*-neomenthylglycine, b.p. 139—141°/11 mm.,  $[\alpha]_D +32.7^\circ$ , with  $\text{N}_2\text{H}_4$  gives *d*-neomenthylglycinehydrazide, m.p. 51°,  $[\alpha]_D +40.0^\circ$ , which affords acetone-, m.p. 79.5°,  $[\alpha]_D +24.5^\circ$ , benzaldehyde-, m.p. 110°,  $[\alpha]_D +20.8^\circ$ , *l*-menthone-, m.p. 102—103°,  $[\alpha]_D -9.0^\circ$ , and *dl*-menthone-*d*-neomenthylglycinehydrazone, m.p. 98—99°,  $[\alpha]_D +9.3^\circ$ . All rotations are in  $\text{CHCl}_3$ . F. R. S.

**Sesquiterpene series. III. Synthesis of 1 : 10-dimethyl-7-isopropyldecyl-2-one.** A. E. BRADFIELD, E. R. JONES, and J. L. SIMONSEN (J.C.S., 1936, 1137—1143).—*l*-Tetrahydracarvone, condensed with  $\text{CH}_2\text{Cl-CH}_2\text{-CO}_2\text{Et}$ , gave fractions, b.p. 172—182°/14 mm. (I) and b.p. 182—240°/14 mm. (II). From (I), following hydrolysis, a liquid acid (semicarbazone, m.p. 186—187°) was obtained, corresponding with  $\text{CHPr}^a < \begin{array}{c} \text{CH}_2\text{---CH}_2 \\ | \\ \text{CH}_2\text{---CO} \end{array} > \text{CMe-}[\text{CH}_2]_2\text{-CO}_2\text{Et}$ . (I) with  $\text{Et}_2\text{C}_2\text{O}_4$  gave a neutral substance (III) and an oil (IV) extracted from the acidified mother-liquors. (III) gave rise to more of (I), whilst (IV), when heated, lost CO, yielding Et 3-carbetoxy-1-methyl-4-isopropylcyclohexan-2-one-1- $\beta$ -propionate, b.p. 186—189°/4 mm.,  $[\alpha]_{5461} -82^\circ$  (semicarbazone, m.p. 155°), which on hydrolysis and re-esterification gave Et 1-methyl-4-isopropylcyclohexan-2-one-1- $\beta$ -propionate (V), b.p.

174°/11 mm.,  $[\alpha]_{5461} -112^\circ$ , the parent acid of which gives the semicarbazone, m.p. 186—187°, above. (V) with  $\text{CH}_2\text{Br}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$  and Zn yielded a main fraction, b.p. <185°/10 mm., and a small fraction b.p. 185—220°/10 mm. Further treatment of the main fraction with the same reagents yielded ultimately a product, b.p. 170—220°/11 mm., and from the fraction boiling up to 190°/11 mm. a 2:4-dinitrophenylhydrazone, m.p. 187—189°. Catalytic reduction of the whole condensation product, led to two fractions, (A) b.p. up to 175°/10 mm., and (B) 175—220°/10 mm., the former of which gave a ketone, b.p. 165—170°/16 mm. (2:4-dinitrophenylhydrazone identical with the above), reduced catalytically to 1:10-dimethyl-7-isopropyldecal-2-one (VI), b.p. 146—155°/11 mm., m.p. 102—103°,  $[\alpha]_{5461} +22.2^\circ$ , [semicarbazone, m.p. 210°; 2:4-dinitrophenylhydrazone, m.p. 221—223° (decomp.)]. In the total distillate some hydrocarbon was apparently present. (VI) when treated with  $\text{MgMeI}$  and then dehydrogenated with Se gave an oil, b.p. 130—160°/14 mm., the picrate and  $s\text{-C}_6\text{H}_5(\text{NO}_2)_3$  derivatives of which had m.p. and mixed m.p. identical with those of 1:2:7- $\text{C}_{10}\text{H}_5\text{Me}_2\text{Pr}^{\text{a}}$ . Et 1:3-dimethylcyclohexan-2-one-3-carboxylate, b.p. 115—116°/16 mm., gives a semicarbazone, m.p. 181°, in the prep. of which 2-carbamyl-3-keto-7:9-dimethyl-3:4:5:6:7:9-hexahydroindazole, m.p. 144—147°, was obtained as by-product. Et 3-carbethoxy-1:3-dimethylcyclohexan-2-ol-2-acetate, b.p. 172—173°/17 mm. (from the above ketone,  $\text{CH}_2\text{Br}\cdot\text{CO}_2\text{Et}$ , and Zn), with  $\text{SOCl}_2$  gave Et 3-carbethoxy-1:3-dimethylcyclohexylidene-2-acetate (VII), b.p. 159°/13 mm., which was hydrolysed to acids, m.p. 148—150°, and m.p. 120—121°, together with the H ester (?). Re-esterification, following hydrolysis, yielded a lactonic acid, m.p. 194—195° (Et ester, b.p. 174—176°/11 mm.), and an isomeric lactonic acid, m.p. 128—129°. Reduction of (VII), in two stages, gave Et 3-carbethoxy-1:3-dimethylcyclohexane-2-acetate, b.p. 155°/12 mm., and 1:3-dimethyl-3-hydroxymethyl-2- $\beta$ -hydroxyethylcyclohexane (VIII), b.p. 150—180°/15 mm. (diacetate, b.p. 136—137°/4 mm.), with an unsaturated alcohol. A by-product in the prep. of (VIII) was 3-carboxy-1:3-dimethylcyclohexane-2-acetic acid, m.p. 185°. 6-Methyl-3:4:5:8-tetrahydrocoumaran-1:2-dione (?), b.p. 170—178°/12 mm., m.p. 139—140°, was obtained from distillation residues of Et 1-methylcyclohexan-2-one-3-carboxylate, and 2-methylcyclohexyl-1-methylcyclohexan-2-one-3-carboxylate, b.p. 181—182°/19 mm. (semicarbazone, m.p. 152—153°; 2:4-dinitrophenylhydrazone, decomp. 109—110°), from by-products of  $\text{Et}_2\text{C}_2\text{O}_4$  condensation. J. T. A.

**Catalytic dehydration of  $\beta$ -fenchyl alcohol.** N. J. TOIVONEN (Suomen Kem., 1936, 9, A, 72—73).—By heating with kaolin to 200°,  $\beta$ -fenchyl alcohol yields  $\beta$ -fenchene; under similar conditions  $\alpha$ -fenchyl alcohol is dehydrated much less readily to a mixture of fenchene and methylsantene. H. N. R.

**Action of isomerisation catalysts on tricyclic hydrocarbons of the terpene series.** N. J. TOIVONEN (Suomen Kem., 1936, 9, A, 75—76).—cycloFenchene is readily polymerised on keeping with

Florida earth; tricyclene and apocyclene are scarcely attacked by this reagent even under drastic conditions.

H. N. R.

**Racemisation of methylsantene.** N. J. TOIVONEN (Suomen Kem., 1936, 9, A, 73—75).—After purification, the methylsantenes obtained by dehydration of  $\alpha$ -fenchyl alcohol (I) with Florida earth and with  $\text{ZnCl}_2$  are optically inactive; a mechanism is suggested to account for this. A tricyclic terpene, b.p. 154—155°, possibly (II), is produced in small amount in the dehydration of (I) with kaolin. H. N. R.

**Primary resin acids.** K. KRAFT (Annalen, 1936, 524, 1—13).—The filtrates obtained after removal of pimaric acids as  $\text{NH}_4$  salts from the crude acids from the resin of *Pinus palustris* are treated with  $\text{CO}_2$  and the liberated acids are again purified through the  $\text{NH}_4$  salts followed by crystallisation, whereby proabietic acid (I),  $\text{C}_{20}\text{H}_{30}\text{O}_2$ , m.p. 159—160°,  $[\alpha]_{\text{D}} +11.5^\circ$  in 96% EtOH, is obtained. It is also obtained from French galipot. It is isomerised by  $\text{HCl}$ -EtOH at room temp. to abietic acid (II), and comparison of the  $[\alpha]_{\text{D}}$ -t graph thus observed with that for the isomerisation of *l*-pimaric acid (III) indicates that it is probably an intermediate product in the latter change. The transformation of (I) and (III) into (II) by boiling AcOH indicates a common C skeleton. The absorption spectrum of (III) indicates the probable presence of three conjugated double linkings (cf. A., 1935, 1372), but treatment of dihydro-*l*-pimaric acid with  $\text{BzO}_2\text{H}$  shows the presence therein of a single double linking, whilst two only are observed in (II) and (III). Probably these are present in the same ring. Ozonisation of (III) does not give  $\text{CH}_2\text{O}$ , indicating thus the absence of terminal  $\text{CH}_2$ . The view that the majority of the sapic acids are mixtures of (III) and *d*-pimaric acid requires modification in view of the isolation of (I). Probably the no. of primary resin acids does not exceed four. H. W.

**Ammoresinol.** H. RAUDNITZ, F. PETRU, E. DIAMANT, K. NEURAD, and K. LANNER (Ber., 1936, 69, [B], 1956—1961).—According to analyses and determinations of mol. wt., diacetylammoresinol (I), m.p. 102—103°, is  $\text{C}_{28}\text{H}_{34}\text{O}_6$ . It contains 2 Ac; hence ammmoresinol (II), m.p. 111°, is  $\text{C}_{24}\text{H}_{30}\text{O}_4$ , confirmed by analysis and mol. wt. determinations. Hydrogenation ( $\text{PtO}_2$  in AcOH) of (I) at 50° yields diacetylhexahydroammoresinol (III), m.p. 64°, unaffected by Br or  $\text{C}(\text{NO}_2)_4$ . Ozonolysis of (I) gives 0.8 mol. of  $\text{COMe}_2$  1:1  $\text{CMe}_2$ . Oxidation of (III) by  $\text{KMnO}_4$  in  $\text{COMe}_2$  affords  $\beta\gamma$ -dimethylundecan- $\kappa$ -one (semicarbazone, m.p. 97°),  $\gamma$ -hydroxy- $\gamma\lambda$ -trimethyldecylolactone (IV), b.p. 130—135°/0.2 mm.,  $\beta$ -resorecylic and 2-hydroxy-4-acetoxybenzoic acid. (IV) is stable to  $\text{SOCl}_2$ . Moderated oxidation of (II) with  $\text{CrO}_3$  gives a saturated acid,  $\text{C}_{20}\text{H}_{20}\text{O}_8$ , m.p. 199°, and an unsaturated neutral substance,  $\text{C}_{22}\text{H}_{26}\text{O}_5$ , m.p. 99°. When heated in a high vac. (I) is decomposed with evolution of gas whereas (II) affords a hydrocarbon,  $\text{C}_{13}\text{H}_{22}$ , b.p. 64°/0.08 mm.

No evidence of a fourth, difficultly saturated double linking is obtained (cf. Spath *et al.*, this vol., 1118).

H. W.

**Rhodocladonic acid.** G. KOLLER and H. HAMBURG (*Monatsh.*, 1936, 68, 202—206).—Rhodocladonic acid,  $C_{16}H_{10}O_8 \cdot OMe$ , decomp. 250—300° (Ac. derivative, m.p. 216—218°), is best purified by sublimation at 210—230°/0.008 mm., is sol. in  $NaHCO_3$  etc., and, when repeatedly recryst. from AcOH, gives an Ac derivative. It is probably a Me tetrahydroxy-hydroxymethylantraquinonecarboxylate.

R. S. C.

**Spirilloxanthin.**—See this vol., 1155.

**Dracorubin, the red pigment of dragon's blood.** I. H. BROCKMANN and R. HAASE (*Ber.*, 1936, 69, [B], 1950—1954).—Powdered Indian dragon's blood is extracted with boiling  $C_6H_6$ ; the cold, filtered extract is treated with picric acid and the ppt. is decomposed with  $KOH-MeOH-H_2O$ . The crude pigment is purified by adsorption with  $Al_2O_3$  thus giving dracorubin (I),  $C_{19}H_{14}O_8$ , m.p. 315° (Berl) (also +0.5  $CHCl_3$  and +1  $MeOH$ ) (picrate; hydrochloride; perchlorate). It does not contain N,  $CMc_2$ , OMe, or active H. Oxidation with  $CrO_3$  (Kuhn) affords 1.7 mol. of acid. (I) is moderately stable to dil.  $KOH-EtOH$  but prolonged boiling with conc. solutions causes decolorisation with production of  $BzOH$  and  $COPhMe$ . Hydrogenation (Pt in  $MeOH$  or  $EtOAc$ ) causes decolorisation and ceases after absorption of 1  $H_2$  and (I) is regenerated from the solution by air. In AcOH decolorisation occurs after absorption of 2  $H_2$  and after that of 5  $H_2$  a colourless product, m.p. 242°, is produced. (I) closely resembles 2-phenylbenzopyran derivatives.

**New pterins.** C. SCHOPF and E. BECKER (*Analen*, 1936, 524, 49—123).—Examination of *Appias nero*, F., *Catopsilia argante*, F., *Euchloe cardamines*, and *Colias edusa* shows the presence of xanthopterin (I), erythropterin (II), and guanopterin (III), whilst in addition to leucopterin (IV) and (I), chrysopterin (V) is isolated from *Gonepteryx rhamni*, L. After a preliminary extraction of the wings with  $Et_2O$  and  $EtOH$  the pterins are isolated and purified by repeated fractional extraction with dil.  $NH_3$  and fractional pptn. or extraction with acid. Chromatographic analysis is useful only for identification or enrichment. They and their derivatives have no definite m.p. and proof of homogeneity rests on absorption spectrum and elementary analysis, particularly the determination of N (Kjeldahl-Friedrich), and isolation of individuals from various sources. They appear to form a complex natural group containing 19 C per mol. in the case of (I), (III), and (IV) and probably also of (II) and (V). The very high N content is characteristic. The individuality of the pterin preps. cannot generally be guaranteed and in some cases there is distinct evidence that they are mixtures of isomerides or closely allied substances.

(II) is obtained from *A. nero*, *E. cardamines*, *C. argante*, *Col. edusa*, and *G. rhamni* and is best freed from (I) by crystallisation from 0.1N-HCl. Analyses of the products thus obtained are not very concordant and are best expressed by  $C_{19}H_{17-18}O_{8-10}N_{13-11}$  in

which  $xO + yN = 20$  or 21. In spite of this uncertainty a peculiar group is at any rate concerned; this is characterised by red colour, relatively low N content, and violet-blue fluorescence in 0.5N-AcOH. (II) is much better adsorbed by (I) by  $Al_2O_3$  from dil. aq. HCl or HCl-MeOH. The solubility of (II) in  $H_2O$  is considerable. It does not give cryst. salts with acids or alkalis. The alkaline-earth salts are very sparingly sol. in hot  $H_2O$  and separation of (II) from (I) by hot aq.  $Ba(OH)_2$  is therefore possible. The Ag and Fe salts are very dark ppts.  $HNO_3$  (conc. and 1 : 1) readily decomposes (II) and the residues do not give the murexide reaction. (II) tends to pass into a dark violet, amorphous transformation product probably of high mol. wt. The absorption spectra of various samples of (II) do not show good concordance.

(I) is best purified by repeated crystallisation of the  $\beta$ -Ba salt (VI), re-analyses of which agree with  $C_{19}H_{14}O_8N_{16}Ba_3$ ; for (I)  $C_{19}H_{14}O_8N_{12}$  is most probable. Analyses and X-ray diagrams of the Ba salt obtained from *A. nero*, *C. argante*, and *S. rhamni* are identical, and preps. of (I) from these sources have identical absorption spectra. As far as can be judged an identical material is derived from *E. cardamines* and *Col. edusa* so that (I) appears chemically homogeneous. During the isolation of (I) from *C. argante* a more acidic isomeride is obtained, converted by aq.  $Ba(OH)_2$  into (VI). During the isolation of (VI) from crude (I) the formation of a dark brown, very sparingly sol. Ba salt is observed from which (V),  $C_{19}H_{16}O_8N_{14}$ , purified through the Na salt, is obtained. Probably it is derived from (I) by replacement of 2 NH by 2 O. Its solution in 0.5N-AcOH has a violet-blue fluorescence. It is more strongly adsorbed than (I) by  $Al_2O_3$  from very dil. aq. HCl, but the difference is less marked from HCl-MeOH.

(III), first observed in *E. cardamines*, is separated from (II) and (IV) by its readier solubility in most acids and from (V) and (I) by its ready solubility in aq.  $Ba(OH)_2$  and purified through the very sparingly sol. sulphate,  $C_{19}H_{22}O_4N_{20} \cdot 2H_2SO_4$ , from which NaOAc liberates it. It is  $C_{19}H_{22}O_4N_{20}$  or, after desiccation at 120°/high vac.,  $C_{19}H_{20}O_3N_{20}$ . Fluorescence is not shown by it or its solutions. It is adsorbed by Frankonit KL. The Ag salt is stable in boiling solution. It does not give the "lepidoporphyrin" reaction when warmed with 20%  $H_2SO_4$  or the murexide reaction with  $HNO_3$ . The absorption spectrum has a single max. at 284  $m\mu$ , probably corresponding with a pyrimidine nucleus.

The possible constitution of the pterins is discussed.

H. W.

**Acetylation of lignin, and its isolation from wood.** II. F. KOMAROV and G. FILMONOVA (*J. Appl. Chem. Russ.*, 1936, 9, 1096—1105).—Acetylation of lignin (I) prepared by the König, Willstätter, and Freudenberg methods gives products yielding respectively 33, 31, and 26.7% of AcOH, whilst the acetylated products of resinification of fructose yield <15% of AcOH. It is concluded that the differences are due to slight modifications of (I) arising from differences in the extraction procedures, but are not due to production of (I) from sugars.

**Ursolic acid. III. Acid from the leaves of *Rhododendron hymenanthos*, Makino.** S. KUWADA and T. MATSUKAWA (J. Pharm. Soc. Japan, 1933, 53, 1065—1070).—Extraction of the leaves with Et<sub>2</sub>O affords  $\beta$ -ursolic acid (I), m.p. 290—291° (decomp.) (acetate, m.p. 294—295°; Me ester of acetate, m.p. 245—246°; Me ester of benzoate, m.p. 215—216°). (I) gives a Me ester, m.p. 230°, with Me<sub>2</sub>SO<sub>4</sub> or, after treatment with alkali, with CH<sub>2</sub>N<sub>2</sub>; with CH<sub>2</sub>N<sub>2</sub> (I) yields another Me ester, m.p. 170—172°.

CH. ABS. (r)

**Bitter constituents of colombo root. III. F. WESSELY, K. SCHÖNOL, and W. ISEMANN** (Monatsh., 1936, 68, 274).—A minor correction (cf. this vol., 995).

R. S. C.

**Bitter principles of colombo root. V. K. FEIST, R. BRACHVOGEL, and W. VOLKSEN** (Annalen, 1936, 523, 289—294; cf. this vol., 730).—COMe<sub>2</sub> is formed from columbin and 50% KOH at about 270°. The K compound of carboxyiso-V-columbin, isolated impure as intermediary product in the prep. of this compound, with Me<sub>2</sub>SO<sub>4</sub>—5% aq. KOH gives the Me ether, C<sub>20</sub>H<sub>21</sub>O·OMe, m.p. 241°. When merochamanthic acid Me ether, m.p. 248°, is distilled with Zn dust, it yields 1 : 2 : 5-C<sub>10</sub>H<sub>14</sub>Me<sub>3</sub> and a trace of a phenol.

R. S. C.

**Constitution of acid sapogenins. X. Hederagenin and oleanolic acid.** Z. KITASATO [with C. SONE and H. SHISHIDO] (Acta Phytochim., 1936, 9, 43—60; cf. A., 1935, 1126).—The following oxidations by CrO<sub>3</sub> in AcOH are recorded: diacetyl-hederagenin to *ketodiacetylhederagenin* (I), m.p. 217° or (+H<sub>2</sub>O) m.p. 162° [Me ester (II), m.p. 237°]; acetyloleanolic acid to *ketoacetyloleanolic acid* (II), m.p. 278° (Me ester, m.p. 237°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +99.2° in CHCl<sub>3</sub>); hederagenin acid to *ketohederagenic acid*, m.p. 275° (decomp.) [Me ester, m.p. 237°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +149.2° in CHCl<sub>3</sub>]; Me<sub>2</sub> hederagenonedicarboxylate to Me<sub>2</sub> *ketohederagenonedicarboxylate*, m.p. 165—166°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +53.7° in CHCl<sub>3</sub>; Me acetyloleanolate to Me *ketodehydroacetyloleanolate*, m.p. 195°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —8.4° in CHCl<sub>3</sub>. The following conversions are effected with HBr—AcOH: (I) to  $\psi$ -ketohederagenin, m.p. >300°; (III) to  $\psi$ -keto-oleanolic acid, m.p. 267—271° (decomp.); ketodiacetylhederageninlactone (IV) to *isoketodiacetylhederagenin* (V), m.p. 275—279°; ketoacetyloleanolactone to *isoketoacetyloleanolic acid* (VII), m.p. 324—330° (Me ester, m.p. 216°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +25.7° in CHCl<sub>3</sub>). The following reductions with Na—Hg are described: (IV) to ketodehydrohederagenin, m.p. >300°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —11.6° in CHCl<sub>3</sub>; ketoacetyloleanolactone to Me ketodihydro-oleanolate, m.p. 198—200°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —19.6° in CHCl<sub>3</sub>;  $\psi$ -ketodiacetylhederagenin to dehydrohederageninlactone;  $\psi$ -ketodiacetylhederagenin Me ester to dehydrohederagenin Me ester, m.p. 219—220° (Ac<sub>2</sub> derivative, m.p. 199°, [ $\alpha$ ]<sub>D</sub> —124.5°); Me  $\psi$ -ketoacetyloleanolate to Me *dehydro-oleanolate*, m.p. 175°; (V) to *isodehydrohederagenin* (Ac<sub>2</sub> derivative, m.p. 247—250°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +222.1°, and its Me ester, m.p. 140—145°, [ $\alpha$ ]<sub>D</sub> +223.3° in CHCl<sub>3</sub>); (VI) to *isodehydro-oleanolic acid* (Ac derivative, m.p. 235°); (V) to *dehydrodiacetylhederagenin*, m.p. 212—215°, after loss of H<sub>2</sub>O of crystallisation at 152°, [ $\alpha$ ]<sub>D</sub> —122.2° in CHCl<sub>3</sub>;

(III) to *dehydroacetyloleanolic acid* (Ac derivative, m.p. 205°, [ $\alpha$ ]<sub>D</sub> —105.9° in CHCl<sub>3</sub> and its Me ester, m.p. 224°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —115.4° in CHCl<sub>3</sub>); (III) to *isodehydrodiacetylhederagenin* Me ester and impure dehydrodiacetylhederagenin Me ester; oleanolic acid to oleanylenic acid (Me ester, m.p. 136—140°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +119.2° in CHCl<sub>3</sub>).

Hedratricarboxylic acid is converted by boiling conc. HCl—MeOH into the Me H<sub>2</sub> ester, m.p. 185°, and by KOH—Me<sub>2</sub>SO<sub>4</sub> followed by HCl—MeOH into the Me<sub>3</sub> ester (VII), m.p. 124°, also obtained by use of CH<sub>2</sub>N<sub>2</sub>. Regulated hydrolysis of (VII) affords the Me<sub>2</sub> H ester. Oxidation of the Me ester of hederagenonedicarboxylomonolactone with CrO<sub>3</sub>—conc. H<sub>2</sub>SO<sub>4</sub>—AcOH yields the Me<sub>2</sub> ester of hedratricarboxylomonolactone, m.p. 170°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> ±0° in CHCl<sub>3</sub>, also obtained from (VII) and HBr—AcOH at room temp., and the monolactone of the Me<sub>3</sub> ester of a tetracarboxylic acid, m.p. 195°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> —23.9° in CHCl<sub>3</sub>.

H. W.

**Constitution of acid sapogenins. XI. Z. KITASATO** (Acta Phytochim., 1936, 9, 61—74).—The conditions of Ruzicka's dehydrogenations are regarded as too drastic to form a completely trustworthy guide to the structure of hederagenin (I) and oleanolic acid (II) and attempts are made to deduce their constitutions from oxidative observations. The presence of the group  $\cdot\text{CMe}(\text{CH}_2\text{OH})\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot$  in ring A is established and the behaviour of hedratricarboxylic acid towards esterification and of its esters towards hydrolysis combined with that of the Me ester of hederagenonedicarboxylomonolactone towards CrO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> in AcOH establishes the possibilities (X) and (VI) for the rings A and B. The presence of a sec.-OH in (II) is established, with the probability that it occupies

the same position as in (I). Reasons are advanced for assigning structure (III) to the ring containing the

double linking and CO<sub>2</sub>H and the results combined with the application of the isoprene rule indicate the constitution (IV) or (V) for (I).

H. W.

**Constitution of acid sapogenins. XII. Z. KITASATO** [with H. SHISHIDO] (*Acta Phytochim.*, 1936, 9, 75—82).—Oxidation of Me *isoketo-oleanolate* with  $\text{CrO}_3\text{--H}_2\text{SO}_4$  in AcOH affords *Me\_3 isoketo-oleanoltricarboxylate*, m.p. 219—220°,  $[\alpha]_D^{25} -16.4^\circ$  in  $\text{CHCl}_3$ , whilst similar treatment of its Ac derivative yields a small amount of substance, m.p. 278°, and much unchanged materials without any tricarboxylic acid or dicarboxylolactone expected on the basis of Ruzicka's formulation (this vol., 477). On the other hand, oxidation of Me *ketoacetyloleanolate* affords the lactone of Me, *acetyloleanoldicarboxylate* (I), m.p. 202—204°,  $[\alpha]_D^{25} +14.8^\circ$  in  $\text{CHCl}_3$ , also obtained from hydroxyacetyl-oleanolactone and identical with Ruzicka's product, so that his scheme is devoid of experimental basis. (I) is hydrolysed by KOH—MeOH to *oleanolpenta-carboxylic acid* (*Me\_5* ester, m.p. 205°,  $[\alpha]_D^{25} -15.5^\circ$  in  $\text{CHCl}_3$ ). Oxidation of dehydro- or  $\psi$ -*keto-diacetyl-hederagenin* Me ester gives substances,  $\text{C}_{35}\text{H}_{55}\text{O}_8$ , m.p. 165° (m.p. 235° after desiccation), and  $\text{C}_{35}\text{H}_{55}\text{O}_7$ .

H. W.

**Constitution of jegosapogenin. II. C. SONE** (*Acta Phytochim.*, 1936, 9, 83—88; cf. A., 1934, 1223).—Jegosapogenol (I) is shown to contain one primary OH (probably esterified by tiglic acid in jegosapogenin), one *sec.* OH, and two acylatable *tert.* OH. Oxidation of tri-bromojegosapogenin with  $\text{CrO}_3$  in AcOH gives the compound,  $\text{C}_{35}\text{H}_{53}\text{O}_6\text{Br}_3$ , m.p. 251° (decomp.). Treatment of (I) with  $\text{Pb}(\text{OAc})_4$  in AcOH gives the *aldoketone*,  $\text{C}_{30}\text{H}_{46}\text{O}_5$ , m.p. 208° (decomp.) (also  $+1\text{H}_2\text{O}$ ) [*dioxime*, m.p. 242° (decomp.)], oxidised by  $\text{CrO}_3$  in AcOH to the *ketolactone*,  $\text{C}_{30}\text{H}_{42}\text{O}_5$  (also  $+1\text{H}_2\text{O}$ ), m.p. 325° (decomp.) from  $\text{CHCl}_3\text{--MeOH}$ , m.p. 351° (decomp.) from EtOAc [*monoxime*, m.p. 298—300° (decomp.) (also  $+1\text{H}_2\text{O}$ ); *monoacetate*, m.p. 348—349°; *monobenzoate* (also  $+2\text{H}_2\text{O}$ ), m.p. 320—325° (decomp.)].

H. W.

**Viburnitol.**—See this vol., 1307.

**Furan series. I. Synthesis of 4-2-ketotetrahydrofurylacetic acid. R. GHOSH** (*J. Indian Chem. Soc.*, 1936, 13, 323—328).— $\text{OMe}\cdot\text{CH}_2\cdot\text{CHO}$ ,  $\text{CH}_2(\text{CO}_2\text{Et})_2$ , and  $\text{C}_5\text{H}_{11}\text{N}$  give a mixture of *Et methoxyethylidene mono-*, b.p. 128—130°/8 mm., and *di-malonate*, b.p. 190—200°/10 mm. The di-ester with HCl yields  $\beta$ -*methoxymethylglutaric acid*, b.p. 184—190°/4 mm. (*anhydride*, m.p. 77—78°; *Et* ester, b.p. 125—135°/8 mm.), which undergoes ring-closure (HCl) to 4-2-ketotetrahydrofurylacetic acid, m.p. 87—88°.

F. R. S.

**Relative aromaticities. VI. 2-Furonitrile. H. GILMAN and M. LICHTENWALTER** (*Rec. trav. chim.*, 1936, 55, 588—590; cf. A., 1934, 778).—The relative rates of reaction of  $\text{MgPhBr}$  with nitriles,  $\text{RCN}$ , are  $p\text{-C}_6\text{H}_4\cdot\text{NMe}_2$  5.1,  $p\text{-C}_6\text{H}_4\cdot\text{OMe}$  3.9,  $\alpha$ - 1.09, and  $\beta\text{-C}_{10}\text{H}_7$  1.64,  $o$ - 1.74,  $m$ - and  $p\text{-C}_6\text{H}_4\cdot\text{Me}$  0.55,  $\text{Ph}$  0.31,  $p\text{-C}_6\text{H}_4\cdot\text{Cl}$  0.09,  $\text{Me}$  0.25,  $\text{Pr}^i$  0.2,  $\text{Bu}^i$  0.17,  $n$ - 0.11, and *iso*- $\text{C}_5\text{H}_{11}$  0.23,  $n\text{-C}_{11}\text{H}_{23}$  0.1,  $n\text{-C}_{17}\text{H}_{35}$  0.09,  $\text{CH}_2\text{Ph}\cdot\text{CH}_2$  0.13,  $\text{OPh}\cdot[\text{CH}_2]_3$  0.11, and 2-furonitrile (I) 0.02. The great reactivity of (I) in Grignard reactions classes (I) as an aliphatic or "super-aliphatic" compound, whereas other reactions class it as "super-aromatic." The reality of "relative aromaticities" is thus doubtful.

R. S. C.

**Catalytic reduction of 2-furylpropylcarbinol. H. KONDO and K. TAKEDA** (*J. Pharm. Soc. Japan*, 1935, 55, 734—740).—Furylpropylcarbinol (I) (*phenylurethane*, m.p. 79.5°) is hydrogenated ( $\text{PtO}_2$ ; 2.5  $\text{H}_2$ ) to *tetrahydrofurylpropylcarbinol*, b.p. 84—88°/12 mm. (*phenylurethane*, m.p. 89°), and octane-8 $\epsilon$ -diol (*bisphenylurethane*, m.p. 193—194°), which is also obtained by hydrogenation of dipropenylethylene. Hydrogenation of (I) with Pd—C gave a substance, b.p. 95—100°/20 mm., and another substance, b.p. 120—125°/20 mm.

CH. ABS. (r)

**Furan and pyrrole derivatives from sugars and ethyl acetoacetate. Relation of the mechanism of this reaction to antiketogenesis. F. GARCÍA GONZÁLEZ** (*Anal. Fís. Quím.*, 1934, 32, 815—829; cf. this vol., 972).—The compound described by West (A., 1927, 1173) as Et dextrosecycloacetate is *Et 5-methyl-2- $\alpha\beta\gamma\delta$ -tetrahydroxybutylfuran-4-carboxylate* (*mono-*, b.p. 155—175°/0.2 mm., and *di-isopropylidene*, b.p. 150—160°/0.2 mm.,  $[\alpha]_D^{20} -10.9^\circ$  in  $\text{CHCl}_3$ , derivatives), oxidised ( $\text{H}_2\text{O}_2$  or  $\text{KMnO}_4$ ) to 5-methylfuran-2:4-dicarboxylic acid, m.p. 270—275° (decomp.) (*dichloride*, b.p. 133—135°/14 mm., m.p. 25—26°; *diamide*, m.p. 210—211°; *dianilide*, m.p. 196—197°; *Me\_2* ester, m.p. 61—62°); this sublimes with loss of  $\text{CO}_2$  at 270—280° to yield 2-methylfuran-3-carboxylic acid (*amide*, m.p. 90°; *anilide*, m.p. 111—112°).

F. R. G.

**Lichen substances. LXIX. Usnic acid. I. Y. ASAHINA and M. YANAGITA** (*Ber.*, 1936, 69, [B], 1646—1649).—Oxidation of usnetic (I) or pyrrousnic acid with 3%  $\text{H}_2\text{O}_2$  in 3% KOH gives 4:5-dicarboxy-3-methylfuran-2-acetic acid, m.p. 251—252° (decomp.) after becoming discoloured at about 220°, the *Me\_3* ester, b.p. 193—195°/10 mm., 162°/2 mm., of which gives an *oximino*-derivative, hydrolysed and dehydrated by  $\text{Ac}_2\text{O}$  at 120° to 2-cyano-3-methylfuran-4:5-dicarboxylic acid (II), m.p. 171—172° after softening at about 165° and m.p. 260° after re-solidification. Decarboxylation of (II) by Cu powder in quinoline at 210° and subsequent hydrolysis of the nitrile yields 3-methylfuran-2-carboxylic acid, thus establishing the position of Me and  $\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ . Since decarboxusnic acid, formed from (I) by elimination of  $\text{COMe}_2$ , condenses with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  to the substance  $\text{C}_{23}\text{H}_{23}\text{O}_4\text{N}_2$  (*hydrochloride*, decomp. 274—275° after softening at 260°), it is  $\text{R}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}_2\text{Ac}$  and usnic acid is

**Addition of iodine to coumarin derivatives. W. RUZICZKA** (*Monatsh.*, 1936, 68, 233—236).—Coumarin, osthol, and ostruthin absorb 0.1985, 0.0601, and 0.0898 mol., respectively, of I.

R. S. C.

**Synthesis of coumarin derivatives. I. T. SAKAI and C. KATO** (*J. Pharm. Soc. Japan*, 1935, 55, 691—704).—4-Methyl-daphnetin [*Me\_2* ether (I), m.p. 132°; *diacetate*, m.p. 178°; *dibenzoate*, m.p. 178°; *dibenzyl ether*, m.p. 157°] yields 3-bromo-4-methyl-daphnetin (II), m.p. 254—255°, and 3:4-dibromo-4-methyl-daphnetin, m.p. 265° [*Me\_2* ether (III), m.p. 138—139°; *dibenzoate*, m.p. 198—199°; *dibenzyl ether*, m.p. 151—152°]. Bromination of (I) gave the *Me\_2* ether

(IV), m.p. 166—167° (*dibenzoate*, m.p. 184—185°; *dibenzyl ether*, m.p. 148—149°), of (II). (III) with KOH yields 3-bromo-6:7-dimethoxy-4-methylcoumaran-2-carboxylic acid (V), m.p. 248°; (IV) similarly yields 6:7-dimethoxy-3-methylcoumarone-2-carboxylic acid, m.p. 188°, whilst the *dibenzoate* of (II), under these conditions, yields 6:7-dibenzoyloxy-3-methylcoumarone-2-carboxylic acid, m.p. 123°, converted into *Et* 6:7-dihydroxy-3-methylcoumarone-2-carboxylate, m.p. 191—192°. The *dibenzyl ether* of (II) similarly yields 6:7-dibenzoyloxy-3-methylcoumarone-2-carboxylic acid, m.p. 184—185°. (V) with HCl in a sealed tube yields a substance,  $C_{22}H_{24}O_6$ , m.p. 127—128°, whilst with  $MgMeBr$  it yields 6-hydroxy-7-methoxy-3-methylcoumarone (?), b.p. 119—122°/1 mm., converted into 6-benzoyloxy-7-methylcoumarone, m.p. 144—145°.

CH. ABS. (r)

Optically active flavanones. II. Optical resolution of hydroxyflavanones. S. FUJISE and A. NAGASAKI (Ber., 1936, 69, [B], 1893—1896; cf. A., 1935, 91).—Treatment of *dl*-demethoxymatteucinol (I) in  $C_6H_5N$  with *l*-menthoxyacetyl chloride (II) in  $C_6H_6$  and repeated crystallisation of the product from MeOH affords *l*-demethoxymatteucinol *l*-menthoxyacetate, m.p. 125—125.5°,  $[\alpha]_D -51.6^\circ$ , which becomes partly racemised when hydrolysed. Similarly, (I) and (II) (2 mols.) give *d*-demethoxymatteucinol *di-l*-menthoxyacetate, m.p. 118—119°,  $[\alpha]_D -81.3^\circ$  in  $COMe_2$ , whence the partly racemised *d*-compound. 7-Hydroxyflavanone and (II) yield *d*-7-hydroxyflavanone *l*-menthoxyacetate, m.p. 96—97°,  $[\alpha]^{14.5} -30.0^\circ$ , whence *d*-7-hydroxyflavanone, m.p. 181—182°,  $[\alpha]_D^{17} +33.3^\circ$ .

H. W.

Anthocyanin of the blue blossoms of *Hyalcinthus orientalis*.—See this vol., 1307.

Spectrographic investigations of the blue pigments of the benzopyrylium type. V. Relationships between the absorption of light and hydroxyl or sugar substitution in the 2-phenylbenzopyrylium pigments. K. HAYASHI (Acta Phytochim., 1936, 9, 1—24).—The following general conclusions are reached. As frequently observed with hydroxyflavones, OMe is spectroscopically similar to OH in the same position. With cyanidin and delphinidin derivatives replacement of OH of the benzopyrylium nucleus by OMe has a more or less hypsochromic effect.  $HO_2CH_2$  behaves similarly to two corresponding vicinal OH or OMe groups. Introduction of acyl or aroyl into flavones is an important method of elucidating their constitution because of the pronounced optical effect but has less significance with anthocyanidins since it does not invariably yield a homogeneous product and not infrequently involves change of structure. Apart from a slight alteration in the shape of the graph, nuclear Me has the same optical effect as H.

Benzopyrylium pigments with a single OH in the benzopyrylium nucleus (I) generally show bands *i* (frequency 1800—2300), *iv* (3400—3800), and *v* (4000—4100) and it is characteristic of the group that *iv* never becomes divided. OH at 5 has a bathochromic effect on *i* and the complete curve becomes more hypsochromic. The influence of 2 OH in (I) is discussed. Introduction of a single OH into

the side Ph (II) causes resolution of *iv* into two bands. Hypsochromism of *i* and *iv* increases in the sequence,  $2' < 3' < 4'$ . Only the pigment with 4'-OH shows the band *iii* (2600—3200) and *v*. Two OH (OMe) groups in (II) generally exert a marked bathochromic effect on *i* and the otherwise usually small and therefore indistinct *iv* becomes better developed and is never divided. *i* is unchanged by alteration of the position of three or four OH (OMe) groups in (II) and *iv* usually consists of a homogeneous, very small band. Introduction of OH at 3 causes bathochromic displacement of *i* by 180—200 units and sometimes induces fission of *iv*; it has no pronounced influence on the other bands. The sugar residue at 3 or 5 in the flavylum mol. appears to exert a not unimportant, diffuse influence on the absorption spectrum. Generally the changes introduced in the spectrum of flavylum derivatives by the position and no. of substituents are not very marked and somewhat complex so that proof of constitution is not so readily secured as with the flavones. Nevertheless the moderately purified aglucone of an unknown anthocyanin can thus be assigned to its anthocyanidin type. The prep. of  $\omega$ -methoxyresacetophenone and its condensation with  $\beta$ -resorcaldehyde to 7:2':4'-trihydroxy-3-methoxyflavylum chloride are described.

H. W.

Thermal decomposition of dioxan.—See this vol., 1208.

1:3-Dioxins. V. Preparation of  $\alpha\beta$ -naphtho-1:3-dioxin and comparison with 1:8-naphtho-1:3-dioxin. M. C. CARNERO and F. CALVET. VI. Condensation of *p*-hydroxybenzoic acid with formaldehyde at low temperatures. M. N. MEJUTO and F. CALVET (Anal. Fis. Quím., 1934, 32, 1157—1167, 1168—1181).—V. 4'-Nitro- $\alpha\beta$ -naphtho-1:3-dioxin (cf. Borsche *et al.*, A., 1904, i, 415) (I) reduced by Zn and HCl yields 4'-amino- $\alpha\beta$ -naphtho-1:3-dioxin, m.p. 107—110° (hydrochloride, decomp. about 225°), which on diazotisation and decomp. of the product with  $SnCl_2$  in KOH yields  $\alpha\beta$ -naphtho-1:3-dioxin, m.p. 35—37° (picrate m.p. 133—135°); this in AcOH with conc.  $HNO_3$  yields (I) and in  $COMe_2$  with  $KMnO_4$  gives  $\alpha\beta$ -naphtho-4-keto-1:3-dioxin, m.p. 65—70° characterised by hydrolysis (dil. NaOH) to 1:2-OH- $C_{10}H_6$ - $CO_2H$ . 1:8- $C_{10}H_6(OH)_2$  in  $COMe_2$  with  $Me_2SO_4$  and dil. NaOH yields 1':8'-naphtho-1:3-dioxin, m.p. 29—30° (picrate, m.p. 135—137°; Br-, m.p. 70—72°; Br<sub>3</sub>-, m.p. 212—214° (decomp.),  $NO_2$ -, m.p. 146—148°;  $NH_2$ -, m.p. 93—95°; 4:5(?)-( $NO_2$ )<sub>2</sub>-, m.p. 198—200° (hydrolysed to a compound, m.p. 218—220°, and reduced to the diamine hydrochloride, m.p. about 310° {decomp.}), derivatives].

VI. *p*-OH- $C_6H_4$ - $CO_2H$  with 2 mols. of para-formaldehyde (I) (cf. Epstein, A., 1910, i, 117) in conc.  $H_2SO_4$  at -15° yields 1:3-benzdioxin-6-carboxylic acid (I), m.p. >350°; excess of (II) at -10° produces 8:8'-di-(6-carboxy-1:3-benzdioxin)methane (III), m.p. >320° ( $Me_2$ , m.p. 175—178°, *Et*<sub>2</sub>, m.p. 138—140°, and *Pr*<sub>2</sub> esters, m.p. 109—111°; *Ag* salt), and 8-hydroxymethyl-1:3-benzdioxin-6-carboxylic acid (IV), m.p. 229—230° (*Me* ester, m.p. 116—118°; *Ac* derivative, m.p. 192—194°). Further action of (I)

on (II) yields (III). 6:1:3-OH·C<sub>6</sub>H<sub>3</sub>(CO<sub>2</sub>H)<sub>3</sub> with (I) gives (IV). *p*-OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H with CH<sub>2</sub>Cl·OH and ZnCl<sub>2</sub> yields 8-chloromethyl-1:3-benzodioxin-6-carboxylic acid, m.p. 201—203°, which with H<sub>2</sub>O gives (IV). (II) in COMe<sub>2</sub> with KMnO<sub>4</sub> yields 4-keto-1:3-benzodioxin. (IV) hydrolysed (2*N*-NaOH) and oxidised (KMnO<sub>4</sub>) yields *Me phenol*-2:4:6-tricarboxylate, m.p. 143—145°, hydrolysed to 1:2:4:6-OH·C<sub>6</sub>H<sub>2</sub>(CO<sub>2</sub>H)<sub>3</sub> (cf. Ullmann *et al.*, A., 1909, i, 590). F. R. G.

**Furylfuran and its derivatives.** II. H. KONDO, H. SUZUKI, and K. TAKEDA (J. Pharm. Soc. Japan, 1935, 55, 741—747).—Reduction (Pd-C) of 2:2'-difuryl (I) affords 2-furyldihydrofuran (II), b.p. 55—60°/8 mm., and a substance, b.p. 95—108°/8 mm. (maleic anhydride adduct, C<sub>12</sub>H<sub>12</sub>O<sub>5</sub>, m.p. 94.5—95°). Hydrogenation (PtO<sub>2</sub>) of a mixture of (I), (II), and furyltetrahydrofuran yields octahydro-2:2'-difuryl, b.p. 77—80°/13 mm., octane- $\alpha$ -diol, m.p. 60°, and a substance, b.p. 120—124°/13 mm. CH. ABS. (r)

**Correlation of toxicity with optical activity of *Derris* derivatives.**—See this vol., 1295.

**Possibility of dynamic isomerism in certain heterocyclic compounds.** E. W. McCLELLAND and C. E. SALKELD (J.C.S., 1936, 1143—1148).—

The compounds  $\text{C}_6\text{H}_4\langle\text{S}\rangle\text{NR}$  (I),  $\text{C}_6\text{H}_4\langle\text{S}\rangle\text{C(NR)}\text{S}$  (II) [R=Me, CH<sub>2</sub>·CH<sub>2</sub>·OH, Ph, NH<sub>2</sub>, or NHPh; (II) R=OH, OMe, or NH·CO<sub>2</sub>C<sub>6</sub>H<sub>11</sub>, and C·NR=C(SH)·NH·NH·CO·NH<sub>2</sub>] have been hydrolysed (HCl) to 2:2'-dithiobenzoic acid and (in most cases) 2-dithiobenzoyl and this is in accord with the equilibrium, (I)  $\rightleftharpoons$  (II). It is suggested that the compounds, (I) or (II), which on treatment with H<sub>2</sub>S give  $\text{C}_6\text{H}_4\langle\text{S}\rangle\text{S}$  and are oxidised to saccharins

are an equilibrium mixture of the two forms, whilst those [(II), R=OH, OMe] which do not react with H<sub>2</sub>S and are oxidised to a sulphone have the structure (II). The oxime, m.p. 208°, of 2:3-dithiosulphindene (III), is oxidised (H<sub>2</sub>O<sub>2</sub>) to a sulphone, m.p. 177°, and the *O-Me ether* of the oxime, m.p. 55°, is oxidised to the corresponding sulphone, m.p. 135°. (III) condenses with NH<sub>2</sub>·[CH<sub>2</sub>]<sub>2</sub>·OH to a substance, m.p. 107° (*Ac* derivative, m.p. 64.5°), with N<sub>2</sub>H<sub>4</sub> to a product, m.p. 125° (with ClCO<sub>2</sub>Et gives a product, m.p. 96°), with NHPh·NH<sub>2</sub> to a solid, m.p. 106°, with semicarbazide to a compound, m.p. 205—212° (with *iso*-C<sub>6</sub>H<sub>11</sub>·OH gives *isoamyl* 1-keto-2:3-dithiobenzohydrazone- $\beta$ -carboxylate, m.p. 105°). The following have been synthesised: 2-methylthiobenzomethylamide, m.p. 140°; 2-methylthiobenzo-, m.p. 71°, and 2-methylthiobenzo-NS-di-methylthioamide, m.p. 68.5°; 2-methylthiobenzomethylamidoxime, m.p. 194°; and 2-methylthiobenzodimethylamide, b.p. 168—170°/10 mm., and -thioamide, m.p. 83°. H<sub>2</sub>Se in EtOH reduces (I) (II) (R=Me) to a thiol, which on methylation (Me<sub>2</sub>SO<sub>4</sub>) gives mainly SMe·C<sub>6</sub>H<sub>4</sub>·C(NMe)·SMe, whilst reduction in Et<sub>2</sub>O and methylation (CH<sub>2</sub>N<sub>2</sub>) yields SMe·C<sub>6</sub>H<sub>4</sub>·CS·NHMe. The significance of the results is discussed.

F. R. S.

**Syntheses by means of magnesylpyrroles.** Series II. XXII. B. ODDO and G. ACUTO (Gaz-

zetta, 1936, 66, 380—386).—The Mg derivative of 2:5-dimethylpyrrole reacts with CO<sub>2</sub>, ClCO<sub>2</sub>Et, and COCl·CH<sub>2</sub>·CO<sub>2</sub>Et, respectively, to form 2:5-dimethylpyrrole-3-carboxylic acid and its Et ester, and *Et* 2:5-dimethylpyrrole-3- $\beta$ -ketopropionate (I), m.p. 62°. (I) is hydrolysed to 3-acetyl-2:5-dimethylpyrrole, and with NHPh·NH<sub>2</sub> yields 1-phenyl-3-(2':3'-dimethyl-3'-pyrryl)pyrazolone, decomp. 247—252°. The Mg derivative of 2:4-dimethylpyrrole and CO<sub>2</sub> give 2:4-dimethylpyrrole-5-carboxylic acid, m.p. 137° (decomp.). E. W. W.

**Catalytic transformations of heterocyclic compounds.** V. Transformation of furan into 1-phenyl-, 1-*o*-tolyl-, and 1-*p*-tolyl-pyrrole. J. K. JURIEV (Ber., 1936, 69, [B], 1944—1948; cf. this vol., 858).—Mixtures of furan with excess of NH<sub>2</sub>Ph, *o*- and *p*-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> when passed over Al<sub>2</sub>O<sub>3</sub> at 465° afford 1-phenyl-, m.p. 61—62°, 1-*o*-tolyl-, b.p. 114°/12 mm., and 1-*p*-tolyl-, m.p. 79—79.5°, -pyrrole respectively in 24%, 40.6%, and 21% yield. Crude furan, b.p. 205—210°, obtained by pyrolysis of pyromucic acid, may be employed. H. W.

**Nitration with nitrogen dioxide.** II. Nitration of pyridine and quinoline. P. SCHORGEN and A. TOPTSCHIEV (Ber., 1936, 69, [B], 1874—1877; cf. A., 1934, 996).—Nitration of C<sub>5</sub>H<sub>5</sub>N vapour by N<sub>2</sub>O<sub>4</sub> in presence of CO<sub>2</sub> proceeds best at 115—120° and gives 3-nitropyridine in 7—10% yield; irradiation with ultra-violet light is without influence. The same yield is obtained at 220—230° whereas at 300—330° violent explosions take place which are also observed with C<sub>5</sub>H<sub>5</sub>N and liquid N<sub>2</sub>O<sub>4</sub> at room temp. Pyridine nitrate, m.p. 117—118°, and nitrite (+1H<sub>2</sub>O), m.p. 58—60°, are described. Quinoline and N<sub>2</sub>O<sub>4</sub> afford 7-nitro- (optimal temp. 95—100°) and 5:7-dinitro- (best at 155—160°) -quinoline. H. W.

**Structure of 2-amino- and 2:6-diaminopyridine.** Hydrolysis of the amino-group in 2-aminopyridine. 2:6-Diamino- and 2-amino-6-hydroxy-pyridine and 7-amino-2-hydroxy-4-methyl-1:8-naphthyridine. O. A. SEIDE and A. T. TITOV (Ber., 1936, 69, [B], 1884—1893).—Evidence is adduced, based mainly on hydrolysis,

that the structure *A* in preference to *B* should be assigned to 2-aminopyridine (I). (I) and 2:6-diaminopyridine (II) are unchanged by conc. aq. or alcoholic alkali at 130° and 2-amino-6-hydroxypyridine (III), m.p. 214° (also +1H<sub>2</sub>O) [hydrochloride (also +1H<sub>2</sub>O); sulphate (C<sub>5</sub>H<sub>6</sub>ON<sub>2</sub>)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub> and +1H<sub>2</sub>O; picrate], and 7-amino-2-hydroxy-4-methyl-1:8-naphthyridine (IV) do not evolve NH<sub>3</sub> when boiled with 10% NaOH. (I) and 70% H<sub>2</sub>SO<sub>4</sub> do not interact at 15° whereas (IV) suffers considerable hydrolysis; (II) rapidly and quantitatively loses 1 NH<sub>3</sub> whilst (III) gives NH<sub>3</sub> probably with opening of the C<sub>5</sub>H<sub>5</sub>N ring. H<sub>2</sub>SO<sub>4</sub>+NaHSO<sub>3</sub> rapidly attacks (II), involving the ring N; under like conditions (I) and 2-pyridone (V) are somewhat affected. (III) is converted by an excess of cold Ac<sub>2</sub>O into the *Ac*. derivative, m.p. 162—163° (decomp.), which does not give a colour

with  $\text{FeCl}_3$  or react with diazo-compounds but is readily halogenated or nitrated. It is hydrolysed by hot  $\text{H}_2\text{O}$  to 2-acetamido-6-hydroxypyridine, m.p.  $213^\circ$ , which gives an intense red-brown colour with  $\text{FeCl}_3$  and closely resembles (V) in acidity. H. W.

**Pyridylmethylamines.** R. GRAF [with G. PERATHONER and M. TATZEL] (J. pr. Chem., 1936, [ii], 146, 88—104).—Reduction of 2-cyanopyridine with  $\text{Cr}(\text{OAc})_2$  and aq. KOH yields 2-pyridylmethylamine (I), b.p.  $82^\circ/12$  mm. [platinichloride,  $\text{C}_6\text{H}_8\text{N}_2\cdot\text{H}_2\text{PtCl}_6\cdot 3\text{H}_2\text{O}$ , m.p.  $245^\circ$ ; aurichloride,  $\text{C}_6\text{H}_8\text{N}_2\cdot 2\text{AuCl}_3$ , m.p.  $186^\circ$ ; picrate, m.p.  $162^\circ$  (decomp.); dihydrobromide, m.p.  $234^\circ$ ; Bz derivative, b.p.  $235^\circ/11$  mm., m.p.  $53^\circ$ ; p-nitrobenzoyl, m.p.  $136^\circ$ , reduced by Sn and HCl in EtOH to the p-aminobenzoyl, m.p.  $94^\circ$ , derivative]. When preserved (I) passes partly into pyridine-2-aldehyde, also obtained from it by the action of  $\text{PhNO}$  in EtOH or of  $\text{SOCl}_2$  in  $\text{Et}_2\text{O}$ . Treatment of (I) with  $\text{AgNO}_2$  in 0.5N-HCl affords 2-pyridylmethyl alcohol, b.p.  $105^\circ/12$  mm. (picrate, m.p.  $158^\circ$ ; platinichloride, m.p.  $177^\circ$ ; p-nitrobenzoate, m.p.  $92^\circ$ , reduced to the p-aminobenzoate, m.p.  $79$ — $80^\circ$ ). Similarly 3-cyanopyridine gives 3-pyridylmethylamine, b.p.  $102$ — $103^\circ/14$  mm. [dihydrochloride, m.p.  $219$ — $220^\circ$ ; platinichloride, decomp. about  $280^\circ$ ; aurichloride, m.p.  $201$ — $202^\circ$  (decomp.) after darkening; p-nitrobenzoyl derivative, m.p.  $188$ — $189^\circ$ ]. 3-Cyano-6-methylpyridine yields the very hygroscopic 6-methyl-3-pyridylmethylamine (II), b.p.  $118$ — $120^\circ/14$  mm., m.p.  $63^\circ$  [dihydrochloride, m.p.  $247^\circ$  (decomp.) when rapidly heated; platinichloride, decomp.  $240^\circ$  after darkening at  $220^\circ$  in preheated bath; aurichloride ( $+1\text{H}_2\text{O}$ ), m.p.  $199^\circ$  in closed capillary; Bz derivative, m.p.  $121$ — $122^\circ$ ; p-nitrobenzoyl derivative, m.p.  $171^\circ$ ]. (II) and  $\text{NaNO}_2$  in  $\text{H}_2\text{SO}_4$  afford 6-methyl-3-pyridylmethyl alcohol, b.p.  $140^\circ/11$  mm. (hydrochloride, m.p.  $102^\circ$ ; p-nitrobenzoyl derivative, m.p.  $136$ — $138^\circ$ ). (II) and  $\text{SOCl}_2$  in  $\text{Et}_2\text{O}$  give 6-methylpyridine-3-aldehyde [phenylhydrazone, m.p.  $143$ — $144^\circ$ , or ( $+1\text{H}_2\text{O}$ ) m.p. about  $115^\circ$  after softening at  $98^\circ$ ]. 4-Cyanopyridine gives 4-pyridylmethylamine, b.p.  $103^\circ/11$  mm. [platinichloride, m.p.  $>300^\circ$  after darkening at  $260^\circ$ ; aurichloride, m.p.  $190^\circ$ ; monohydrobromide, m.p.  $240^\circ$  (decomp.); Bz derivative, m.p.  $240^\circ/11$  mm., m.p.  $108^\circ$ ]. Pyridine-4-aldehydephenylhydrazone has m.p.  $175^\circ$ . 4-Pyridylmethyl alcohol b.p.  $140$ — $142^\circ/12$  mm., m.p. about  $40^\circ$ , gives a hydrochloride, m.p.  $164^\circ$  (decomp.), platinichloride, m.p.  $220^\circ$ , and aurichloride, m.p.  $138^\circ$ . 2:6-Dicyanopyridine, m.p.  $123^\circ$ , is reduced to 2:6-diaminomethylpyridine (trihydrochloride, decomp.  $250^\circ$  after darkening at  $230^\circ$ ; platinichloride; aurichloride, decomp.  $180^\circ$  after darkening; Bz derivative, m.p.  $190^\circ$ ), apparently accompanied by 6-methyl-2-pyridylmethylamine. 2-Cyanoquinoline affords 2-quinolylmethylamine, b.p.  $104^\circ/10$  mm. (dihydrochloride, m.p.  $205^\circ$ ; platinichloride, decomp.  $220$ — $225^\circ$ ). 2:3:5:6-Tetrachloro-4-cyanopyridine, m.p.  $138^\circ$ , affords 2:3:5:6-tetrachloro-4-pyridylmethylamine, m.p.  $62$ — $63^\circ$  (monohydrochloride, decomp.  $265^\circ$  after darkening when rapidly heated). 2:4:6-Trichlorobenzonitrile yields 2:4:6-trichlorobenzylamine, m.p.  $62^\circ$  (hydrochloride, m.p.  $247^\circ$ ).

[With W. LANGER.] Me nicotinate is converted

into 3-pyridyldimethylcarbinol, b.p.  $130^\circ/11$  mm., m.p.  $53^\circ$  (benzoate, m.p.  $53^\circ$ , and its hydrochloride; p-nitrobenzoate, m.p.  $157^\circ$ , reduced to the p-aminobenzoate, m.p.  $130^\circ$ ). H. W.

**Derivatives of a dicyclic condensed ring system formed from two pyrrole rings [pyrrolizine].** F. MICHEEL and W. KIMPEL (Ber., 1936, 69, [B], 1990—1993).—Treatment of 5-carbethoxy-4-methyl-3-ethylpyrrole-2-vinyl- $\omega\omega$ -dicarboxylic acid,  $\text{C}(\text{CO}_2\text{Et})\cdot\text{NH}>\text{C}\cdot\text{CH}:\text{C}(\text{CO}_2\text{H})_2$ , with boiling  $\text{Ac}_2\text{O}$

(I.)

affords  $\text{CO}_2$  and Et 3:3-dihydroxy-5-methyl-6-ethylpyrrolizine-4-carboxylate (I), m.p.  $234$ — $235^\circ$  (decomp.), which is unchanged when heated in xylene, and does not react with  $\text{NH}_4\text{OH}$  or  $\text{NHPh}\cdot\text{NH}_2$  or yield an Ac derivative with  $\text{Ac}_2\text{O}$ . Its structure is deduced from its transformation by 0.2N-NaOH-MeOH into 3-hydroxy-3-methoxy-5-methyl-6-ethylpyrrolizine-4-carboxylic acid, m.p.  $242^\circ$ . Et 3-hydroxy-3-ethoxy-5-methyl-6-ethylpyrrolizine-4-carboxylate, m.p.  $127.5^\circ$ , is described. H. W.

**Oxidation of acetyltetrahydroquinolinesulphonic acids.** K. V. BOKIL (J. Indian Chem. Soc., 1936, 13, 404—409).—Quinoline-8-sulphonic acid (prep. described) with Sn-HCl affords tetrahydroquinoline-8-sulphonic acid, the K salt of which with  $\text{Ac}_2\text{O}$  at  $135$ — $140^\circ$  affords K N-acetyltetrahydroquinoline-8-sulphonate ( $+1.5\text{H}_2\text{O}$ ), which with aq. 5%  $\text{KMnO}_4$  at room temp. affords mainly  $\text{K}_2$  2-oxalvalacetamido-3-carboxybenzenesulphonate (I) ( $+0.5\text{H}_2\text{O}$ ) and some  $\text{K}_1$  salt. (I) with boiling dil. HCl affords K 2-oxalamido-3-carboxybenzenesulphonate ( $+1.5\text{H}_2\text{O}$ ). K N-acetyltetrahydroquinoline-5-sulphonate ( $+1\text{H}_2\text{O}$ ) with aq.  $\text{KMnO}_4$  at room temp. affords mainly  $\text{K}_2$  2-acetamido-6-sulphobenzoylformate (II) ( $+1.5\text{H}_2\text{O}$ ) and some  $\text{K}_1$  3-acetamido-2-carboxybenzenesulphonate ( $+1\text{H}_2\text{O}$ ) and  $\text{K}_1$  3-amino-2-carboxybenzenesulphonate ( $+1\text{H}_2\text{O}$ ). (II) with warm conc. HCl affords K isatin-4-sulphonate. J. L. D.

**Nitroso-derivative of 4-hydroxycarbostyryl.** A. MEYER and P. HEIMANN (Compt. rend., 1936, 203, 335—337).—The product (I) of the nitrosation of 4-hydroxycarbostyryl (II) separates from EtOH or from  $\text{H}_2\text{O}$  if the solution is rapidly cooled to about  $15^\circ$  in yellow, thermolabile crystals which pass into the red variety at about  $100^\circ$ . From aq. solution at  $>40^\circ$  thermostable yellow crystals, m.p.  $251^\circ$ , separate which lose  $1\text{H}_2\text{O}$  when dried at  $140^\circ$ ; it cannot be diazotised. Since CO cannot be detected in (I) by  $\text{NH}_2\text{OH}$  or  $\text{NHPh}\cdot\text{NH}_2$  and (I) is fixed by metallic mordants the formulæ  $\text{C}_6\text{H}_4\cdot\text{N}=\text{C}(\text{OH})\cdot\text{C}(\text{NO})\cdot\text{OH}$  or

are suggested in place of  $\text{C}_6\text{H}_4\cdot\text{N}=\text{C}(\text{OH})\cdot\text{C}(\text{NO})\cdot\text{OH}$ . (II) is transformed in alkaline solution into 2-hydroxy-4-methoxyquinoline, m.p.  $271^\circ$ , the NO-derivative, m.p.  $220^\circ$ , of which forms greenish-yellow crystals, unchanged by heat and with slight affinity for metallic mordants. (I) yields a Na salt, converted by  $\text{CoCl}_2$  in  $\text{H}_2\text{O}$  into the complex,

$C_9H_5O_3N_2Co(OH)_2$ , giving with HCl the substance  $(C_9H_5O_3N_2)_3Co$ . The salt,  $(C_9H_5O_3N_2)_2Na$ , is described. H. W.

**Halogenation of oxidation products of 2:4-dihydroxyquinoline.** A. MEYER and P. HEIMANN (Compt. rend., 1936, 203, 264—266).—At room temp. 2:4-dihydroxyquinoline (I) in  $HCO_2H$  containing the theoretical amount of Br affords a  $Br_1$ -derivative, m.p. 199° (converted by  $PBr_5$  into a  $Br_3$ -derivative, m.p. 276°, in which 1 Br is in the aromatic nucleus, and when oxidised affords 2:4-dihydroxyquinolinic acid), and with excess of Br in warm  $HCO_2H$  affords 3-bromo-2:4-dihydroxyquinoline, m.p. 281° (converted by  $PBr_5$  into 2:3:4-tribromoquinoline, m.p. 288°, and oxidised to 3-bromo-2:4-dihydroxyquinolinic acid, m.p. 240°). In boiling  $C_6H_6$  with Br, (I) affords a  $Br_1$ -derivative, m.p. 241°. J. L. D.

**Manufacture of 3-aminoquinoline derivatives.**—See B., 1936, 876.

**Azo-dyes from quinolonemethides.** E. KOENIGS and H. BUEREN (J. pr. Chem., 1936, [ii], 146, 119—128).—Gradual addition of quinaldine methosulphate and 2N-NaOH to  $PhN_2Cl$  at 3° gives 1-methyl-2-benzeneazomethylene-1:2-dihydroquinoline, m.p. 141° [hydrochloride, m.p. 241° (decomp.)]; coupling takes 1—2 min. after each addition. Similarly are prepared 1-methyl-2-anisole-p-, m.p. 185° (hydrochloride, m.p. 245°), -phenetole-p-, m.p. 178° (hydrochloride, m.p. 239°), -naphthalene-1'- (hydrochloride, m.p. 242°), -p-aminobenzene- (dihydrochloride, m.p. 242°), -2'-hydroxy-4'-methylquinoline-7'- [hydrochloride, m.p. 252° (decomp.)], and -2'-ethoxy-4'-methylquinoline-7'-azomethylene-1:2-dihydroquinoline (hydrochloride, m.p. 247°), 6-methoxy-1-methyl-2-benzene- (hydrochloride, m.p. 263°), -anisole-p- (hydrochloride, m.p. 258°), and -naphthalene-1'-azomethylene-1:2-dihydroquinoline (hydrochloride, m.p. 256°), 1:6-dimethyl-2-naphthalene-1'-azomethylene-1:2-dihydroquinoline (hydrochloride, m.p. 245°), 1-methyl-2-di-(anisole-p-azo)methylene-1:2-dihydroquinoline (hydrochloride, m.p. 183°), 1-methyl-4-benzene- [hydrochloride, m.p. 246° (decomp.)] and -naphthalene-1'-azomethylene-1:4-dihydroquinoline [hydrochloride, m.p. 256° (decomp.)]. 7-Amino-2-ethoxy-4-methylquinoline, m.p. 106°, is prepared from the 2-Cl-base and NaOEt at 130°. R. S. C.

**7-Hydroxyquinoline-8-aldehyde.** L. KOCHANŠKA and B. BOBRANŠKI (Ber., 1936, 69, [B], 1807—1813).— $m-NO_2 \cdot C_6H_4 \cdot NH_2$  is converted (Skraup) into 7-nitroquinoline, reduced by Fe powder and conc. HCl at 110—120° to 7-aminoquinoline, which is transformed by conc. HCl at 200° into 7-hydroxyquinoline (I), m.p. 239° after becoming black at 200°. (I), very conc. aq. NaOH, and  $CHCl_3$  afford 7-hydroxyquinoline-8-aldehyde (II), m.p. 133—133.5° [also +  $3H_2O$ ; phenylhydrazone, m.p. 181.5° after softening and darkening at 175°; oxime (III), m.p. 201° (decomp.) after darkening at 195°], which does not reduce Fehling's solution and only slowly darkens  $Ag_2O \cdot NH_3$ . (III) is transformed by boiling  $Ac_2O$  into 8-cyano-7-hydroxyquinoline, m.p. 240°, which with NaOH and  $Me_2SO_4$  yields 8-cyano-7-methoxyquinoline (IV), m.p. 140—141°. 8-Nitro-7-methoxyquinoline (V) is reduced to 8-amino-7-methoxyquinoline, trans-

formed through the diazo-compound into (IV), which is very resistant towards acid and alkali. Treatment with a large excess of conc. HCl at 170° causes hydrolysis and subsequent loss of  $CO_2$  with production of (I). Boiling conc. HCl transforms (V) into 8-nitro-7-hydroxyquinoline, m.p. 252—253° (decomp.) after darkening at 220°, the constitution of which is established by its conversion into 7-chloro-8-nitroquinoline, m.p. 185°. 8-Nitro-7-hydroxyquinoline, KI, red P, and boiling HI give 8-aminoquinoline, m.p. 65°. H. W.

**Action of iodine monochloride solutions on heterocyclic bases.** K. GLEU and W. JAGEMANN (J. pr. Chem., 1936, [ii], 145, 257—264).—Solutions of ICl in HCl, prepared from  $KIO_3$ , KI, and HCl, with bases form salts of  $HICl_2$ , some of which lose HCl when washed. Thus  $C_5H_5N$  forms  $C_5H_5N \cdot HICl_2$  and  $C_5H_5N \cdot ICl$ ; quinoline gives  $C_9H_7N \cdot HICl_2$  and  $C_9H_7N \cdot ICl$ , m.p. 157°; isoquinoline gives  $C_9H_7N \cdot HICl_2$ , m.p. 155°, and  $C_9H_7N \cdot ICl$ , m.p. 158°; acridine gives  $C_{13}H_9N \cdot HICl_2$ , m.p. 220°, stable to  $H_2O$ ; o-phenanthroline gives  $C_{12}H_8N_2 \cdot HICl_2$ , m.p. 167°, stable to  $H_2O$ ; and p-phenanthroline gives  $C_{12}H_8N_2 \cdot 2HICl_2 \cdot 2H_2O$ , m.p. 197°. Under similar conditions 8-hydroxyquinoline gives its 5-I- and 5:7-I<sub>2</sub>-derivatives, 8-aminoquinoline its 5-I-, m.p. 125°, and 5:7-I<sub>2</sub>-, m.p. 151°, derivatives, 5-hydroxyquinoline its 8-I-, m.p. 153°, and 6:8-I<sub>2</sub>-, m.p. 134° (decomp.), derivatives; 5- and 6-aminoquinoline give, respectively, their iodochloride, m.p. 198°, and iodochloride hydrochloride, m.p. 206°, and 6-hydroxyquinoline its iodochloride, m.p. 252° (decomp. from 225°). H. G. M.

**Action of phosphorus pentachloride on derivatives of diphenylamine.** R. R. GOODALL and W. O. KERMACK (J.C.S., 1936, 1163—1166).—Cyclisation of 4-methoxy- and 4-chloro-diphenylamine-2'-carboxylic acid is effected by refluxing with  $PCl_5$  in  $PhCl$  (8 hr.; 130°) forming 5-chloro-3-methoxy-, m.p. 148—149° (lit. 152—153°), and 3:5-dichloroacridine (I) m.p. 196—198°, respectively. (I) with boiling aq. HCl gives 3-chloroacridine, m.p. 398°, and with  $PhOH \cdot KOH$  (2 hr.; 100°) affords 3-chloro-5-phenoxyacridine, m.p. 144—145°. 2:4-Dichloro-, 2:5-dichloro-, and 2-bromo-4-methyldiphenylamine-2'-carboxylic acid, m.p. 191° (from  $o-C_6H_4Cl \cdot CO_2K$ , 3-bromo-p-toluidine, and Cu-bronze at 150° during 4 hr.), similarly treated undergo substitution prior to ring-closure to form 2:4:4'-trichloro-, m.p. 188—189° [acid, m.p. 270° (identical with that obtained from 2:5- $C_6H_3Cl_2 \cdot CO_2K$  (II), 2:4- $C_6H_4Cl_2 \cdot NH_2$ , and Cu-bronze in  $C_6H_{11} \cdot OH$  at 150° during 6 hr.)]; Me ester, m.p. 124°; Ph ester, m.p. 108—109°]; a mixture of 2:5:4'- (III) and 2:4:5-trichloro- (?); and 4'-chloro-2-bromo-4-methyldiphenylamine-2'-carboxylic chloride [acid, m.p. 235—237° (identical with that obtained from (II), 3-bromo-p-toluidine, and Cu-bronze), respectively. Pure (III), m.p. 125—126°, is obtained from the corresponding acid, m.p. 254—255°, which results from the interaction of (II), 2:5- $C_6H_3Cl_2 \cdot NH_2$ , and Cu-bronze. F. N. W.

**Acridones. IX. Acridine 10-oxide and 5-hydroxyacridine 10-oxide.** I. TANASESCU and E. RAMONTIANU (Ber., 1936, 69, [B], 1825—1826).—

*ms*-Chloroacridine is oxidised by  $\text{BzO}_2\text{H}$  to 5-chloroacridine 10-oxide, hydrolysed by alkali to Kliegl's "N-hydroxyacridone" which therefore is 5-hydroxyacridine 10-oxide (I). The assumption of tautomeric

is invalidated by the observation that the absorption spectrum of (I) is the same in abs. EtOH as in alkaline solution and that a change of structure does not therefore accompany salt formation.

H. W.

**Anthraquinone derivatives** [carbazoles and acridines].—See B., 1936, 780.

**Benzosemiflavanthrene. I. Reduction.** C. F. KOELSCH (J. Amer. Chem. Soc., 1936, 58, 1325—1326).—N-o-Diphenylphthalimide, m.p. 165—166° [from o-C<sub>6</sub>H<sub>4</sub>Ph·NH<sub>2</sub> and o-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>O at 200°], is converted by ZnCl<sub>2</sub> at 275°/1 min. into o-9-phenanthridylbenzoic acid (I), m.p. 268—270° (decomp.) (Me ester, m.p. 150—151°), which when distilled with Cu(OAc)<sub>2</sub> gives 9-phenylphenanthridine. (I) and conc. H<sub>2</sub>SO<sub>4</sub> at 160° afford benzosemiflavanthrene (II), m.p. 221—222°, which is of little use as a dye. Reduction of (II) with alkaline Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> affords the H<sub>2</sub>-derivative (III) (O → OH; N → NH), m.p. 197°; SnCl<sub>2</sub> and AcOH-HCl lead to the deoxy-derivative (IV) [(III) with :O=H<sub>2</sub>]. Treatment of (III) with Ac<sub>2</sub>O, BzCl-C<sub>5</sub>H<sub>5</sub>N, or boiling aq. HCl causes disproportionation to (II) and (IV). (IV) is converted by HNO<sub>2</sub> into (II).

H. B.

**γ-Ethylidenecanaline.**—See this vol., 1297.

**1-Phenyl-2:3-dimethyl-5-pyrazolone and its 4-dimethylamino-derivative.**—See B., 1936, 908.

**Alkoxyphenyliminazoles.**—See B., 1936, 907.

**Di- and tri-alkylbarbituric acids.** H. A. SHONLE and W. J. DORAN (J. Amer. Chem. Soc., 1936, 58, 1358—1359).—The following are generally prepared from  $\text{CRR}'(\text{CO}_2\text{Et})_2$  and  $\text{CO}(\text{NH}_2)_2$  or  $\text{NHAlk}\cdot\text{CO}\cdot\text{NH}_2$  in EtOH-NaOEt: 5-methyl-5-isoamyl-, m.p. 124.5—125.2° (lit. 108°), -5-n-hexyl-, m.p. 168—169°, -5-α-methylamyl-, m.p. 173—174°, and -5-β-ethylhexyl-, m.p. 132—132.5°; 5-α-methylamyl-5-allyl-, b.p. 218—220°/7 mm.; 5-n-propyl-5-β-methylbutyl m.p. 129—130.5°; 1:5-dimethyl-5-n-amyl-, m.p. 108—109°, -5-isoamyl m.p. 106—107°, -5-α-methylbutyl-, m.p. 116—117°, -5-α-methylamyl-, b.p. 180°/3 mm., -5-n-hexyl- [decomp. on attempted distillation to N-α-methyloctoyl-N'-methylcarbamide (?), b.p. 189°/3 mm., m.p. 63—64°], and -5-β-ethylhexyl- [decomp. when kept at room temp. to N-α-methyl-γ-ethyloctoyl-N'-methylcarbamide (?), m.p. 65—70°]; 1-methyl-5-ethyl-5-n-propyl-, m.p. 94.5—95°, -5-iso-butyl-, m.p. 90—91°, -5-sec.-butyl-, m.p. 94—95°, -5-n-amyl-, b.p. 155—156°/1 mm., -5-α-methylbutyl-, b.p. 188—190°/7 mm., and -5-β-ethylhexyl-; 1-methyl-5-α-methylbutyl-, b.p. 148—150°/1 mm., and -5-α-methylamyl-5-allyl-; 1:5-diethyl-5-isoamyl-, b.p. 192—194°/13 mm. and -5-α-methylbutyl-, b.p. 148—150°/1 mm., -barbituric acids. Pharmacological data are

given. Et methylisoamyl-, b.p. 103—104°/3 mm., methyl-n-hexyl-, b.p. 125°/3.5 mm., methyl-α-methylamyl-, b.p. 126°/6 mm., α-methylamylallyl-, b.p. 139°/5 mm., methyl-β-ethylhexyl-, b.p. 126°/1.5 mm., methyl-n-amyl-, b.p. 99°/8 mm., methyl-α-methylbutyl-, b.p. 124°/10 mm., and n-propyl-β-methylbutyl-, b.p. 100°/1 mm., -malonates are prepared usually using the AlkBr.

H. B.

**N-Alkyl- and N-aryl-substituted barbituric acids.** D. L. TABERN and E. H. VOLWILER (J. Amer. Chem. Soc., 1936, 58, 1354—1356).—The following are generally prepared from  $\text{CR}_2(\text{CO}_2\text{Et})_2$  or  $\text{CN}\cdot\text{CR}_2\cdot\text{CO}_2\text{Et}$  and  $\text{NHR}'\cdot\text{CO}\cdot\text{NH}_2$ : 1:5-dimethyl-5-α-methylbutyl-, m.p. 105—108°, -5-α-ethylpropyl-, -5-cyclohexenyl-, -5-sec.-butyl-, m.p. 81—83°, -5-isopropyl-, m.p. 113—114°, -5-β-ethylbutyl-, m.p. 98—100°, -5-α-methylamyl-, and -5-α-γ-dimethylbutyl-; 1-methyl-5-ethyl-5-α-methylbutyl-, α-ethylpropyl-, -sec.-butyl-, -isopropyl-, m.p. 124—125°, and -β-ethylbutyl-, m.p. 63—65°; 1-methyl-5-sec.-butyl-5-allyl-; 5-methyl-1-ethyl-5-α-methylbutyl-, -sec.-butyl-, and -isopropyl-, m.p. 106—107°; 1:5-diethyl-5-isopropyl-; 5-methyl-5-α-methylbutyl-1-allyl-; 5-methyl-5-sec.-butyl-1-β-methylallyl-, m.p. 130°; 1-phenyl-5-ethyl-5-α-methylbutyl-; 5:5-diethyl-1-sec.- and -tert.-butyl-, m.p. 83—85° and 98°, respectively; 1-n-butyl-5-sec.-butyl-; 5-methyl-5-α-methylbutyl-1-n- and -tert.-butyl-; 5-α-γ-dimethylbutyl-, m.p. 235°; 5-methyl-, m.p. 205°, and 5-ethyl-, m.p. 175°, -5-α-γ-dimethylbutyl-barbituric acids. Some of the acids show promise as short-acting intravenous hypnotics and anaesthetics.

H. B.

**Phenyl nitrogen substitution and reactivity in barbituric acid series.** D. NIGHTINGALE and L. C. MORRIS (J. Amer. Chem. Soc., 1936, 58, 1469—1470; cf. A., 1932, 283; Cope, *ibid.*, 523).—5:5-Dibromobarbituric acid (I) reacts rapidly with  $\text{NH}_2\text{Ph}$  in EtOH to give p-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub> and 5-bromobarbituric acid (II) [stable  $\text{NH}_2\text{Bu}^a$  salt, obtained similarly in 73% yield from (I) and  $\text{NH}_2\text{Bu}^a$ ]. 5:5-Dibromo-1-phenylbarbituric acid (III) reacts more slowly yielding p-C<sub>6</sub>H<sub>4</sub>Br·NH<sub>2</sub> and 5-bromo-1-phenylbarbituric acid (IV) [unstable  $\text{NH}_2\text{Bu}^a$  salt, m.p. 110—120° (decomp.), when prepared from (IV); obtained less pure in small yield from (III) and  $\text{NH}_2\text{Bu}^a$  in C<sub>6</sub>H<sub>6</sub> (not EtOH)]. Cryst. products could not be similarly obtained from 5:5-dibromo-1:3-diphenylbarbituric acid (V). (I) or (II) with  $\text{NHR}\cdot\text{CS}\cdot\text{NH}_2$  gives 9-phenyl-, m.p. 240° (decomp.), 9-o-tolyl-, m.p. 275° (decomp.), and 9-allyl-, m.p. 270° (decomp.), -8-thio-ψ-uric acids; (III) or (IV) similarly affords 1-phenyl-, m.p. >300° [from  $\text{CS}(\text{NH}_2)_2$ ], 1:9-diphenyl-, m.p. 280° (decomp.), and 1-phenyl-9-allyl-, m.p. >300°, -8-thio-ψ-uric acids, whilst (V) and 5-bromo-1:3-diphenylbarbituric acid do not react to any appreciable extent. (III) and (V) with α-C<sub>10</sub>H<sub>7</sub>·NH·NH<sub>2</sub>·HCl in EtOH give 1-phenyl-, m.p. 292°, and 1:3-diphenyl-, m.p. 303°, -allozan-α-naphthylhydrazones, respectively. 1-Phenyl- and 1:3-diphenyl-barbituric acids appear to react with  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$  and  $\text{NHPh}\cdot\text{CH}\cdot\text{NPh}$  at about the same rate (cf. this vol., 864).

H. B.

**Mechanism of the narcosis induced by hypnotics. II. Synthesis of coloured derivatives of**

phenobarbital [5-phenyl-5-ethylbarbituric acid]. A. E. PIERCE and M. M. RISING (J. Amer. Chem. Soc., 1936, 58, 1361—1363; cf. A., 1933, 958).—Nitration (method: Bousquet and Adams, A., 1930, 351) of phenobarbital gives 60% of 5-*m*-nitrophenyl- (I), new m.p. 283—284°, and some 5-*p*-nitrophenyl-, m.p. 216—217°, -5-ethylbarbituric acid. (I) is reduced (Adams) to the 5-*m*-aminophenyl derivative (II), m.p. 208—209°, converted (diazo-method) into the 5-*m*-hydroxyphenyl derivative (III) (+2H<sub>2</sub>O), m.p. (anhyd.) 199.5—200°, which has no hypnotic activity. Diazotised (II) coupled with *m*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>, (II), and (III) affords pharmacologically inactive dyes, m.p. 221—222°, decomp. 210°, and decomp. about 280°, respectively. A method for the micro-determination of diazoamino-N is described. H. B.

5-Ethyl-5-β-ethylhexylbarbituric acids.—See B., 1936, 860.

Homologues of histamine and their pharmacological actions. Y. TAMAMUSHI (J. Pharm. Soc. Japan, 1933, 53, 1080—1088).—2-Methyl-5-hydroxymethylglyoxaline-4-carboxylic acid is converted by SOCl<sub>2</sub> into 2-methyl-5-chloromethylglyoxaline-4-carboxylic acid hydrochloride, which, with KCN, yields 2-methyl-5-cyanomethylglyoxaline-4-carboxylic acid, m.p. 224°, reduced (Na—EtOH) to 2-methyl-5-(β-aminoethyl)glyoxaline-4-carboxylic acid hydrochloride (I), decomp. 237°, accompanied by 2-methylglyoxaline-4-carboxylic-5-acetic acid, decomp. 242°. (I), when heated, yields 2-methyl-5-β-aminoethylglyoxaline hydrochloride, m.p. 217°, which is 1.3 times as active, physiologically, as histamine. CH. ABS. (r)

Synthesis of *d*-carnosine, the enantiomorph of the naturally occurring form. Its depressor effect on the blood pressure. V. DU VIGNEAUD and M. HUNT (J. Biol. Chem., 1936, 115, 93—100).—*l*-Histidine with Ac<sub>2</sub>O—aq. NaOH at 50—55° affords acetyl-*l*-histidine and thence (hydrolysis; resolution by the *d*-tartrate; esterification) *d*-histidine *Me* ester dihydrochloride, m.p. 197° (corr.), [α]<sub>D</sub><sup>20</sup> —9.8° in H<sub>2</sub>O, which yields carbobenzyloxy-*d*-carnosine, m.p. 161° (corr.), [α]<sub>D</sub><sup>24</sup> —11° in H<sub>2</sub>O, and thence *d*-carnosine (I), m.p. 260°, [α]<sub>D</sub><sup>20</sup> —20.4° in H<sub>2</sub>O (hydrochloride, m.p. 245°). *dl*-Carnosine (II), m.p. 260°, and *l*-carnosine hydrochloride, m.p. 245°, are prepared. (I), (II), and *l*-carnosine (III) are crystallographically identical, as are the *d*- and *l*-hydrochlorides. (I) is without effect on the blood pressure of anaesthetised cats or rabbits. (II) has half the effect of (III). R. S. C.

Optically active di- and tetra-methylspiro-5:5-dihydantoin. (SIR) W. J. PORE and J. B. WHITWORTH (Proc. Roy. Soc., 1936, A, 155, 1—11).—*l*-spiro-5:5-Dihydantoin (I) (A., 1932, 171) and Et<sub>2</sub>O—CH<sub>2</sub>N<sub>2</sub> in COMe<sub>2</sub> give 3:7-dimethyl- (II), m.p. 307—308° (decomp.) (softens at 300°), [α]<sub>D</sub><sup>20</sup><sub>461</sub> —100.7° in MeOH, or tetramethyl- (III), m.p. 188—189°, [α]<sub>D</sub><sup>17</sup><sub>461</sub> —36.4° in MeOH, -*l*-spiro-5:5-dihydantoin. 3:7-Dimethyl-*d*-spiro-5:5-dihydantoin (IV), m.p. 307—308° (decomp.) (softens at 300°), [α]<sub>D</sub><sup>17</sup><sub>461</sub> +100.9° in MeOH [1:9-Bz<sub>2</sub>, m.p. 168—169°, [α]<sub>D</sub><sup>13</sup><sub>461</sub> +187.1° in COMe<sub>2</sub>, and 1:9-Ac<sub>2</sub>, m.p. 183—184°, [α]<sub>D</sub><sup>13</sup><sub>461</sub> —15.7° in COMe<sub>2</sub>, derivatives, obtained by

methylation (Et<sub>2</sub>O—CH<sub>2</sub>N<sub>2</sub>) of the 1:9-Bz<sub>2</sub>, m.p. 307—308° (decomp.) (darkens at 280°), and 1:9-Ac<sub>2</sub>, m.p. 262—263°, derivatives, respectively, of *d*-spiro-5:5-dihydantoin (V), are slowly hydrolysed by MeOH to (IV)], can be similarly prepared from (V). The rotatory dispersions of (I)—(V) in neutral solvents are normal and nearly congruent, indicating ketonic structures. (II) undergoes enolisation in aq. NaOH; hydrolysis to 3:8-dimethylallantoin (which appears to exist in cold aq. NaOH in an optical form, but becomes racemic during isolation or in warm solution) then occurs. The absence of racemisation during methylation of (I) and (V) or their acyl derivatives indicates great configurational stability. 1:9-Dibenzoyl-*dl*-spiro-5:5-dihydantoin is similarly methylated to the 1:9-Bz<sub>2</sub> derivative, m.p. 196—197°, of 3:7-dimethyl-*dl*-spiro-5:5-dihydantoin, m.p. 297—298° (1:9-Ac<sub>2</sub> derivative, m.p. 175—176°; similarly prepared), further methylated to the tetramethyl-*dl*-dihydantoin, m.p. 225—226°; these results prove the constitutions assigned to (II), (III), and (IV). H. B.

3-Pyridylpyridinium salts. P. BAUMGARTEN (Ber., 1936, 69, [B], 1938—1944).—Oxidation of C<sub>5</sub>H<sub>5</sub>N with K<sub>2</sub>S<sub>2</sub>O<sub>8</sub> in H<sub>2</sub>O at 100° and treatment of the product with 20% HClO<sub>4</sub> gives 2-pyridylpyridinium monoperchlorate, m.p. 211.5—212.5°, and 3-pyridylpyridinium diperchlorate (I), m.p. 277.5—280° (slight decomp.) after softening [monoperchlorate, m.p. 170—172°, obtained from (I) and boiling EtOH or by aq. NaHCO<sub>3</sub>; dihydrochloride (II); monoplaticchloride, decomp. >300°]. The constitution of (I) is established by its hydrolysis by alkali to the compound 3-C<sub>5</sub>H<sub>4</sub>N·N:CH:CH:CH:CH:CH·ONa (III), transformed by NH<sub>2</sub>Ph and HCl into glutaconaldehydianil hydrochloride and 3-aminopyridine (IV). Addition of conc. HCl to the solution of (III) causes production of glutacondialdehyde (V) and α-3-pyridyl-amino-ε-3-pyridylimino-Δ<sup>α</sup>-pentadiene, isolated as the perchlorate dihydrochloride, m.p. 158° [corresponding trihydrochloride (VI) (+0.5H<sub>2</sub>O), m.p. 175—176°]. In HCl (III) and (IV) yield (VI), which passes in hot solution into (II) and (IV). H. W.

Preparation and physiological properties of some 2-phenyl-4:5:6:7-tetrahydroisindazolones. J. LEE and W. G. CHRISTIANSEN (J. Amer. Pharm. Assoc., 1936, 25, 691—694).—2-Phenyl-4:5:6:7-tetrahydroisindazol-3-one (I) with Me<sub>2</sub>SO<sub>4</sub> and Et<sub>2</sub>SO<sub>4</sub> affords the 1-*Me*, m.p. 105.5—106.5°, and 1-*Et* derivative, m.p. 108—110°, respectively. Methylation of the 6-*Me* derivative yields the 1:6-*Me*<sub>2</sub> derivative, m.p. 105—106°. Et 3-methylcyclohexanone-6-carboxylate with NPh·NH<sub>2</sub> gives 2-phenyl-5-methyl-4:5:6:7-tetrahydroisindazol-3-one, m.p. 198—201°, methylation of which affords the 1:5-*Me*<sub>2</sub> derivative, m.p. 110—110.5°. Et 3-methylcyclohexanone-2-carboxylate with NPh·NH<sub>2</sub> yields the phenyl-hydrazone, m.p. 136—138°, which with Na affords the 7-*Me* derivative of (I), m.p. 176°. (I) with NaOEt followed by CH<sub>2</sub>·CBr·CH<sub>2</sub>·Br gives the 1-β-bromoallyl derivative (unstable oil). The above compounds possess antipyretic activity and moderate toxicity (rats, mice). F. O. H.

Reaction of certain diazosulphonates derived from  $\beta$ -naphthol-1-sulphonic acid. XV. Derivatives of 2'-nitro-4'-methylbenzene-2-naphthol-1-diazosulphonate and synthesis of 2-(2'-nitro-4'-methylphenylamino)isoindolinone-3-acetic acid. F. M. ROWE, A. S. HAIGH, and A. T. PETERS (J.C.S., 1936, 1098—1108; cf. this vol., 737).—The previous investigations have been extended to compounds derived from *m*-nitro-*p*-toluidine (I). 2 : 1-OH·C<sub>10</sub>H<sub>6</sub>·SO<sub>3</sub>Na and diazotised (I) give 2'-nitro-4'-methylbenzene-3-naphthol-1-diazosulphonate, which with Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O gives Na 1-(2'-nitro-4'-methylbenzeneazo)- $\beta$ -naphthaquinone-1-sulphonate (II). This when treated with NaOH and then HCl gives Na benzaldehyde-2'-nitro-4'-methylphenylhydrazide- $\omega$ -sulphonate-2- $\beta$ -acrylic acid (III), which with boiling HCl·H<sub>2</sub>O gives benzo-2'-nitro-4'-methylphenylhydrazide-2- $\beta$ -acrylic acid (IV), m.p. 224—244° with ring-closure and partial decomp., and 2-(2'-nitro-4'-methylphenylamino)isoindolinone-3-acetic acid (V), m.p. 248° [Me ester (VI), m.p. 167°; anilide, m.p. 258°], also obtained by boiling the former acid with H<sub>2</sub>O, EtOH, AcOH, or PhNO<sub>2</sub>, or better by refluxing the mixture of these two acids with Ac<sub>2</sub>O·C<sub>6</sub>H<sub>5</sub>N, and treating the resulting 2 : 5-diketo-3-(2'-nitro-4'-methylphenyl)isoindolinopyrazolidocoline (VII), m.p. 233°, with warm conc. H<sub>2</sub>SO<sub>4</sub> and then pouring on to ice. (VII) can also be obtained from (V) with Ac<sub>2</sub>O·C<sub>6</sub>H<sub>5</sub>N, PCl<sub>3</sub>, or SOCl<sub>2</sub>, and is reduced by Fe-AcOH to 2 : 5-diketo-3-(2'-amino-4'-methylphenyl)isoindolinopyrazolidocoline (VIII), m.p. 233° [Ac<sub>2</sub> derivative (IX), m.p. 194°]. Neither (VII) nor (VIII) reacts with *p*-nitrophenylhydrazine. (VIII) when refluxed (4 hr.) with PhMe and PCl<sub>3</sub>, or when heated to the b.p. with dil. H<sub>2</sub>SO<sub>4</sub> and then basified, gives 2 : 2'-anhydro-2 : 5-diketo-3-(2'-amino-4'-methylphenyl)isoindolinopyrazolidocoline (X), m.p. 242° [sulphate (XI), m.p. 269° (decomp.); picrate, m.p. 239°]. *o*-Carboxycinnamionitrile when treated successively with PCl<sub>5</sub> at 100° and (after removal of POCl<sub>3</sub>) *m*-nitro-*p*-tolylhydrazine in CHCl<sub>3</sub> gives benzo-2'-nitro-4'-methylphenylhydrazide-2- $\beta$ -acrylonitrile, m.p. 201° from PhMe, which with MeOH-HCl gives (VI), hydrolysed to the acid. (VII), (V), or (IV) when refluxed with aq. NaOH-EtOH is converted into 1-hydroxy-6-methyl-1 : 2 : 3-benzotriazole (cf. J.C.S., 1922, 121, 720) and a little *o*-carboxycinnamic acid (good prep. described), m.p. 205° with conversion into phthalideacetic acid, m.p. 152° [diamide, m.p. 228° (cf. lit.); dianilide, m.p. 172°], also obtained when *o*-cyanocinnamic acid is boiled with aq. HCl. *o*-Cyanocinnamic acid (*allo* or *trans*) when refluxed with aq. NaOH gives isoindolinone-3-acetic acid, m.p. 182° (amide, m.p. 221°), also obtained when *o*-carboxycinnamdiamide is refluxed with aq. NaOH. (V) or (VII) is reduced by aq. NaOH-Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> to 2-(2'-amino-4'-methylphenylamino)isoindolinone-3-acetic acid (XII), m.p. 185° (decomp.) [Me ester hydrochloride, m.p. 204° (decomp.)], which does not form an Ac derivative, but yields (IX), and gives (X), instead of an anilide, in presence of PCl<sub>3</sub> and PhMe. (XII) with cold 10% H<sub>2</sub>SO<sub>4</sub> and NaNO<sub>2</sub> gives 2-(5'-methyl-1' : 2' : 3'-benzotriazolyl)isoindolinone-3-acetic acid, m.p. 253° (amide, m.p. 214°; anilide, m.p. 221°; Me ester). (X) or (XI) but not (XII) when refluxed with dil. H<sub>2</sub>SO<sub>4</sub> gives 2-(2'-aminophenylamino)isoindolinone-3-

acetic acid lactam, m.p. 231° (picrate, m.p. 226°). Na H 3-(2'-nitro-4'-methylphenyl)-3 : 4-dihydrophthalazine-1-sulphonate-4-acetate is obtained (a) when (II) is kept at room temp. for 2 days and then acidified, (b) when (III) is kept similarly with 20% NaOH or heated (sealed vessel; 150°; 6 hr.), and is converted by boiling aq. HCl into 1-hydroxy-3-(2'-nitro-4'-methylphenyl)-3 : 4-dihydrophthalazine-4-acetic acid (XIII), m.p. 233° [Me ester, m.p. 169°; N-Me ether, 1-keto-3-(2'-nitro-4'-methylphenyl)-2-methyltetrahydrophthalazine-4-acetic acid, m.p. 187—188° (decomp.)], which when refluxed (66 hr.) with Ac<sub>2</sub>O·C<sub>6</sub>H<sub>5</sub>N gives (VII), and is reduced by Fe-AcOH-H<sub>2</sub>O to the corresponding 2'-NH<sub>2</sub>-acid (XIV), m.p. 180—200° (impure) [lactam (XV), m.p. 282—284°]. (XV) is stable to hot mineral acids (cf. lower homologue and its 4'-Cl-derivative, this vol., 737) and is not reduced (SnCl<sub>2</sub>, Sn-HCl, or Zn-H<sub>2</sub>SO<sub>4</sub>) to 5-methyl-*o*-benzylenebenzimidazole. (XIV) or (XV) with acid dichromate gives a substance m.p. 311—313° (decomp.); 2'-amino-3-phenyl-4'-methylphthalaz-1-one-4-acetic acid lactam or 2'-amino-3-phenyl-4' : 4'-dimethylphthalaz-1-one were not obtained (cf. loc. cit.). (XIII) when refluxed with aq. H<sub>2</sub>SO<sub>4</sub> gives 2'-nitro-3-phenyl-4'-methylphthalaz-1-one (XVI), m.p. 256—258°, which when heated (120°) with PhNO<sub>2</sub>-Me<sub>2</sub>SO<sub>4</sub> gives the 1-OMe-derivative, m.p. 119—121° from MeOH and m.p. 115—117° from EtOH, decomposed by heat but without formation of 4-keto-1-methoxy-3-(2'-nitro-4'-methylphenyl)-3 : 4-dihydrophthalazine. (XIII) is oxidised by aq. KMnO<sub>4</sub> to 1 : 4-diketo-3-(2'-nitro-4'-methylphenyl)-tetrahydrophthalazine, m.p. 286—288°, of which the Ag salt, when refluxed with EtI·C<sub>6</sub>H<sub>5</sub>, gives 4-keto-1-ethoxy-3-(2'-nitro-4'-methylphenyl)-3 : 4-dihydrophthalazine, m.p. 185° (contains C<sub>6</sub>H<sub>6</sub> of cryst.). (XIII) is oxidised by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>-H<sub>2</sub>SO<sub>4</sub>-H<sub>2</sub>O to 2'-nitro-3-phenyl-4' : 4'-dimethylphthalaz-1-one (XVII), m.p. 236°, the Me derivative of which could not be purified. Reduction of (XVI) and (XVII) with aq. Na<sub>2</sub>S does not give the corresponding NH<sub>2</sub>-compounds. H. G. M.

Synthesis of pyrroles with attached isocyclic ring. A. TREIBS [with F. DORNBERGER, A. ALBRECHT, C. G. SCHRODER, H. REINECKE, and H. EMMERICH] (Annalen, 1936, 524, 285—294; cf. A., 1935, 870).—Gradually addition of a mixture of cyclohexene  $\psi$ -nitrosite and Zn dust to a boiling solution of CH<sub>2</sub>Ac·CO<sub>2</sub>Et in AcOH affords Et 2-methyl-4 : 5 : 6 : 7-tetrahydroindole-3-carboxylate (I), m.p. 133° (yield 35%), and octahydrophenazine (II); possibly the change occurs through the NH<sub>2</sub>-ketone but the imino-amine is also possible. 1 : 2-Dioximes can also be used in this variation of Knorr's synthesis; thus (CMe·N·OH)<sub>2</sub> and CH<sub>2</sub>Ac·CO<sub>2</sub>Et give Et 2 : 3 : 5-trimethylpyrrole-4-carboxylate, m.p. 103—105°. The very unstable cyclopentene  $\psi$ -nitrosite, m.p. 69—70°, passes into Et 4 : 5-cyclopenteno-2-methylpyrrole-3-carboxylate, m.p. 146°, and dicyclopentenopyrazine, m.p. 88—89°, in poor yield. CH<sub>2</sub>Cl·CHO and cyclohexanone in NH<sub>3</sub> give 4 : 5 : 6 : 7-tetrahydroindole (III), m.p. 55°. A more suitable initial material is chlorocyclohexanone, which with CH<sub>2</sub>Ac·CO<sub>2</sub>Et and 10% NH<sub>3</sub> at 60—70° affords (I) (best method of prep.) and with Et<sub>2</sub>C<sub>2</sub>O<sub>4</sub> gives 3-carbethoxy-4 : 5 : 6 : 7-tetrahydroindole-1-carboxylic acid (IV), m.p. 212°

(decomp.). Hydrolysis of the latter with boiling 10% KOH involves loss of  $\text{CO}_2$  and gives 4 : 5 : 6 : 7-tetrahydroindole-3-carboxylic acid (V), m.p.  $201^\circ$  (decomp.) [Et ester, m.p.  $78^\circ$ , also obtained by treatment of (IV) with HCl in boiling EtOH or by decarboxylation of (IV) at  $230^\circ$ ]. At  $210^\circ$ , (V) passes into (III). The substance,  $\text{C}_{20}\text{H}_{27}\text{O}_4\text{N}_3$  or  $\text{C}_{20}\text{H}_{29}\text{O}_4\text{N}_3$ , m.p.  $240^\circ$  (decomp.), is obtained as by-product of the prep. of (IV). (II) and Br in  $\text{H}_2\text{O}$  give a very unstable *perbromide*,  $\text{C}_{12}\text{H}_{16}\text{N}_2\cdot 2\text{Br}_2$ , converted by short treatment with  $\text{COMe}_2$  into *octahydrophenazine dihydrobromide*, decomp.  $210^\circ$ , and by more prolonged treatment into the *monohydrobromide*, decomp.  $160^\circ$ . A complex acid, (?)  $\text{C}_{22}\text{H}_{32}\text{O}_6\text{N}_2$ , m.p.  $194^\circ$  (decomp.), is obtained as by-product of the prep. of (IV).

H. W.

Modern purine chemistry, facts and explanations. H. BILTZ (J. pr. Chem., 1936, [ii], 145, 65—228).—A comprehensive review; the interpretation of results is based on the electronic theory of valency and stereochemical considerations.

H. G. M.

Synthesis of urobilin (urobilin-IX $\alpha$ ) and its isomerides urobilin-III $\alpha$  and -XIII $\alpha$ . W. SIEDEL and E. MEIER (Z. physiol. Chem., 1936, 242, 101—132).—Aldehydoneoxanthobilirubinic acid with colloidal Pd in 0.1N-NaOH and  $\text{H}_2$  gives *aldehydoneobilirubinic acid* (I), m.p.  $228^\circ$  (corr.), and similarly *aldehydoneoxanthobilirubinic acid* gives *aldehydoneobilirubinic acid* (II), m.p.  $242^\circ$  (corr.). (I) mixed with *isoneobilirubinic acid* (III) in AcOH and treated with 2N-HCl under  $\text{N}_2$  at  $70$ — $80^\circ$  gives urobilin (IV), m.p.  $177^\circ$  (corr.) [hydrochloride, m.p.  $199$ — $200^\circ$ ; hydrobromide, m.p.  $200$ — $201^\circ$  (corr.)], also obtained in 25% yield from mesobilirubinogen (V) by heating in AcOH at  $70$ — $80^\circ$  for 30 min. Similarly (II) with neobilirubinic acid (VI) gives (IV). (III) in  $\text{HCO}_2\text{H}$  at  $70$ — $80^\circ$  with  $\text{Ac}_2\text{O}$  gives urobilin-III $\alpha$ , m.p.  $183^\circ$  (corr.) [hydrochloride, m.p.  $203^\circ$  (corr.)]. (I) with (VI) in AcOH and (VI) with  $\text{HCO}_2\text{H}$  and  $\text{Ac}_2\text{O}$  give urobilin-XIII $\alpha$  (VII), m.p.  $176^\circ$  (corr.) [hydrochloride, m.p.  $192^\circ$  (corr.); hydrobromide, m.p.  $194^\circ$  (corr.)]. Mesobilirubin-IX $\alpha$  obtained during the production of (IV) from (V) has m.p.  $301^\circ$  (corr.). The constitution and properties of stercobilin (VIII),  $\text{C}_{33}\text{H}_{46}\text{O}_6\text{N}_4$ , very closely resemble those of (IV), but (VIII) is derived from urobilinogen by a more complicated process. Fuming  $\text{HNO}_3$  gives with (IV) hydrochloride a substance (IX) probably derived from methylethylmaleimide (X), and with (VII) hydrochloride (IX) and (X).  $\text{H}_2\text{SO}_4$ - $\text{CrO}_3$  give with (VII) hydrochloride (IX) and two other substances. (VII) hydrochloride with colloidal Pd and  $\text{H}_2$  in 0.1N-NaOH and with Na-Hg gives mesobilirubinogen-XIII $\alpha$ , m.p.  $194^\circ$ . (I) with  $\text{CH}_2\text{N}_2$  gives a substance, m.p.  $176^\circ$ , but no Me ester.

W. McC.

Porphyrins. XXXVII. Constitution of *Spirographis-hæmin*. H. FISCHER and C. VON SEEMANN (Z. physiol. Chem., 1936, 242, 133—157; cf. this vol., 1128, 1273; Warburg *et al.*, A., 1932, 292).—10.6 kg. of *S. Spallanzanii* yielded 260 mg. of the  $\text{Me}_2$  ester of *Spirographis-hæmin* (I). Treatment of the corresponding porphyrin (II) with HI in air results in a shift towards blue in the spectrum

and the product yields no oxime. The oxime of (II) yields the corresponding nitrile on boiling with  $\text{Ac}_2\text{O}$ . The  $\text{Me}_2$  ester of (II) reacts with  $\text{CHN}_2\cdot\text{CO}_2\text{Me}$  and the product (III) yields an oxime (IV). In (III) the spectrum is shifted towards red, but in (IV) towards blue. The product of hydrogenation ( $\text{Pd-H}_2$ ) of the  $\text{Me}_2$  ester of (II) has m.p.  $242$ — $243^\circ$  and is identical with 1 : 2 : 3 : 5 : 8-pentamethyl-4-ethylporphyrin-6 : 7-dipropionic acid and hence (II) is 2-aldehydo-1 : 3 : 5 : 8-tetramethyl-4-vinylporphyrin-6 : 7-dipropionic acid. The  $\text{Me}_2$  ester of (I) fused with resorcinol yields deuteroporphyrin-IX. 6-Aldehydopyrroporphyrin Me ester in  $\text{HCO}_2\text{H}$  treated with  $\text{Pd-H}_2$  and then oxidised with air gives the corresponding 6-Me derivative, m.p.  $247$ — $248^\circ$ .

W. McC.

Hydrogenated benzisotetrazoles.—See B., 1936, 825.

Chlorophyll. LXIX. Chlorophyll-b. VIII. Purpurins, rhodins, and rhodinoporphyrins from chlorophyll-b. Analogies between chlorophyll-a and -b. H. FISCHER and K. BAUER (Annalen, 1936, 523, 235—284; cf. A., 1935, 763; this vol., 1128).—Many reactions of chlorophyll-b derivatives are reported analogous to those in the -a series, there being no differences except sometimes in conditions and yields, due to the 3-CHO of the -b derivatives. This CHO causes a shift of absorption towards the red and differences in  $\text{Et}_2\text{O}$  colour. Substances with Me at 3,  $\text{CH}_2\cdot\text{CO}_2\text{H}$ , Me,  $\text{CO}_2\text{H}$ , or H at  $\gamma$ , and H or  $\text{CO}_2\text{H}$  at 6 belong to the chlorin type (green  $\text{Et}_2\text{O}$  colour, broad spectrum); substances which are similar except that they have CHO instead of Me at 3 are rhodins (red  $\text{Et}_2\text{O}$  colour, narrow spectrum), but are converted into substances of chlorin type by masking of the CO, *e.g.*, by oximation. Unstable rhodins or chlorins exist in the hydrate form (A), which reverts to the CO form when the  $\text{CO}_2\text{H}$  is esterified; this assumption explains the ready formation of anhydride-purpurins, which occurs by loss of  $\text{HCO}_2\text{H}$  as shown in the partial formulæ (A)—(C). *cyclo*Propanecarboxylates formed by reaction of the  $\text{CH}\cdot\text{CH}_2$  with  $\text{CHN}_2\cdot\text{CO}_2\text{Me}$  are called below “D-products”; spectrographic evidence of this reaction or of oximation, without isolation of the products, is reported below as “positive D- or O-reaction,”

respectively.  $[\alpha]$  are  $[\alpha]_{6900}^{0-7300}$  in  $\text{COMe}_2$ . The D-product of the  $\text{Me}_2$  ester of rhodin-g<sub>7</sub> gives an

oxime,  $C_{36}H_{33}O_5N_5(OMe)_4$ , m.p. 229°, which in boiling  $C_5H_5N$  gives a *pyrophosphoribide-b* derivative,  $C_{37}H_{33}O_4N_5(OMe)_2$ , m.p. 278°; decarboxylation has occurred and this can thus no longer be ascribed to the vicinity of the  $CH:CH_2$  and  $CHO$  in the *-b* series, since in this case the  $CH:CH_2$  and  $CHO$  were masked. Rhodin-*g*, in hot  $C_5H_5N$  gives 30–60% of rhodin-*g*<sub>5</sub> (I) and 10% of rhodin-*g*<sub>5</sub>- $\gamma$ -hydroxymethyl-lactone (II) [*Me* ester, m.p. 215°,  $[\alpha] -431^\circ$  (*Cu* salt, m.p. 162°; *oxime*, m.p. 235°; *D-product*, m.p. 240°)], which decomposes at 230° to yield a little 3-demethyl-3-formylphyllporphyrin (III). The *Me*<sub>2</sub> ester (IV), m.p. 180°,  $[\alpha] -566^\circ$  [*Cu*, m.p. 191°,  $[\alpha] -515^\circ$  (with HI gives a little rhodoporphyrin-*g*<sub>6</sub>), and *Zn* salt], of (I) gives an oxime, m.p. 214°, which with  $Ac_2O-KOAc$  gives the nitrile,  $C_{33}H_{31}O_2N_5(OMe)_2$ , m.p. 181° (*Cu* salt, m.p. 188°,  $[\alpha] -629^\circ$ ). Rhodinporphyrin-*g*<sub>5</sub>,  $C_{33}H_{32}O_3N_4(OMe)_2$  (analysed), purified by the *Fe* salt, m.p. 286°, with  $HI-AcOH-O_2$  gives a substance, the *Me* ester,  $C_{33}H_{31}O_3N_4(OMe)_3$ , m.p. 214°, of which gives no oxime; the *Fe* salt of rhodin-*g* *Me*<sub>3</sub> ester gives similarly a substance, esterified to rhodin-*g*<sub>8</sub> *Me*<sub>4</sub> ester. Phæophorbide-*b* and  $NaOMe-C_5H_5N$  at 140–150° give rhodoporphyrin and traces of phyllo- and pyrrro-porphyrins; (IV) gives a little phylloporphyrin. (II) resists acylation and alkaline hydrolysis and was not obtained from rhodin-*g*-ester, but with  $HI$  in  $N_2$  gives rhodinporphyrin-*g*<sub>5</sub> and a little -*g*<sub>6</sub>.  $C_5H_5N$ -degradation of chlorin-*e*<sub>6</sub>, analogous to that of (I), gives similarly chlorin-*e*<sub>4</sub> and 3% of chlorin-*e*<sub>4</sub>- $\gamma$ -hydroxymethyl-lactone [cf. formula (II)], m.p. 166° (*D*-reaction positive); the lactone with  $HI$  gives chloroporphyrin-*e*<sub>4</sub> very rapidly. (I), m.p. 212°, at 225° gives 1 mol. of  $CO_2$ , rhodin-*g*<sub>3</sub> (V),  $C_{32}H_{31}O_3N_4$  (decomposes entirely on attempted further decarboxylation; *Me* ester, m.p. 243°,  $[\alpha] -428^\circ$ ; positive *O*- and *D*-reactions), and (III), m.p. 233° [negative *D*-reaction; also obtained by short heating of (I) with  $HI$  at 70°, and in 2% yield with (V) by decarboxylation of rhodin-*g* (VI); *oxime*, m.p. 244°].

(VI) in boiling  $HCO_2H$  gives rhodinporphyrin-*g*<sub>3</sub> (*Me* ester, m.p. 230°, and *oxime*, m.p. 275°, give negative *D*-reactions). Chlorin-*e* gives similarly a 5% yield of a *phyllporphyrin* (*Me* ester, m.p. 227°). (VI) and cold  $HCl-MeOH$  give 60% of rhodin-*g*<sub>7</sub> (VII),  $C_{34}H_{32}O_7N_4$ , the *Me*<sub>2</sub> ester, m.p. 274°,  $[\alpha] -230^\circ$  (*Cu* salt, m.p. 246°), of which (a) at about 285° or in

boiling  $Ph_2$  gives  $CO_2$  and 5% of isorhodin-*g*<sub>5</sub> *Me*<sub>2</sub> ester (VIII), m.p. 255°,  $[\alpha] -424^\circ$  [positive *O*- and

*D*-reactions; with  $HI$  at 70° and subsequently  $CH_2N_2$  gives a *porphyrin* (IX),  $C_{33}H_{32}O_3N_4(OMe)_2$ , m.p. 253°, and (b) with  $HI$  at 60° gives *rhodinporphyrin-g-lactone Me*, ester (X),  $C_{34}H_{30}O_5N_4(OMe)_2$ , m.p. 258°, a *porphyrin* (XI),  $C_{34}H_{32}O_5N_4(OMe)_2$ , m.p. 268° [also obtained by decarboxylation of (X) by melting], and a little (IX). The *O*-reactions of (IX), (X), and (XI) are positive, the *D*-reactions negative. When phæophorbide-*b* or methylphæophorbide-*b* is shaken with

20%  $KOH-PrOH-Et_2O$ , there are formed a trace of (VI) and, nearly quantitatively, an unstable rhodin (XII), which, when esterified ( $CH_2N_2$ ), changes its type and yields *b-phæopurpurin-7 Me*<sub>3</sub> ester (XIII),  $C_{34}H_{29}O_5N_4(OMe)_3$ , m.p. 252°,  $[\alpha] +481^\circ$  (*D*-reaction positive; *oxime*, m.p. 238°; a *dioxime* is indicated spectrographically, but could not be isolated); cold, acid hydrolysis of this ester gives a stable purpurin acid, which was not, however, isolated crystalline. If (XIII) is repeatedly evaporated in  $Et_2O$  and then heated at 130° or kept for months in  $Et_2O$ , a 35% yield of *b-phæopurpurin-18* (XIV),  $C_{33}H_{30}O_6N_4$ , m.p. >360° (previous decomp.),  $[\alpha] +340^\circ$  [*Me* ester, m.p. 282°, spectrographically identical with (XIV), both before and after hydrolysis; *D*- and *O*-reactions positive], is obtained. (XII) and  $HCl-Et_2O-MeOH$  give (XIII). With  $KOH-PrOH$ , rhodin-*g* *Me*<sub>3</sub> ester or pure phæophytin-*b* gives (XIII) quantitatively, but (VI) and chlorin-*e* are largely unchanged, and mixtures of phæophytin-*a* and -*b* or chlorophyllide-*a* and -*b* give mixtures of phæopurpurin-7 and -18. Rhodin-*g*-oxime gives the oxime of (XIII). Phæophorbide-*b* and  $KOH-MeOH$  give (VI), but no (XIII). (XIII) in hot  $C_5H_5N$  gives a good yield of 3-demethyl-3-formyl- $\psi$ -verdoporphyrin (XV),  $C_{34}H_{28}O_3N_4(OMe)_2$ , m.p. 250° (*O*-reaction positive; also obtained with another product by 20%  $HCl$ ), which with  $CHN_3 \cdot CO_2Me$  gives the *D-product*, m.p. 228° (*O*-reaction positive). (XIV) and  $KOH-MeOH$  give *b-chlorin-p*<sub>6</sub>, which with  $CH_2N_2$  yields the *Me*<sub>3</sub> ester (XVI),  $C_{33}H_{29}O_4N_4(OMe)_3$ , m.p.

261°,  $[\alpha] +249^\circ$  (*D*- and *O*-reactions positive). In hot  $C_5H_5N$  (XIV) is largely decomposed, but gives a little *b-rhodoporphyrin-g-carboxylic anhydride* and a *porphyrin*, also obtained from (XVI) by  $HI$ . The  $CO-CO_2Me$  of (XIII) is removed by boiling with 20%  $KOH-PrOH$  for 3 min.; *b-rhodochlorin* (XVII) [*Me*<sub>3</sub> ester,  $C_{35}H_{30}O_3N_4(OMe)_2$ , m.p. 198°,  $[\alpha] -230^\circ$ , =the 5 : 6- $H_2$ -derivative of (XV); *O*- and *D*-reactions positive] and a little (XV) are obtained. (XIII) or (XVII) with  $HI$  give a poor yield of *b-rhodoporphyrin*,  $C_{32}H_{30}O_3N_4(OMe)_2$ , m.p. 218° (*O*-reaction positive; *D*-reaction negative).

R. S. C.

**Chlorophyll. LXX.** Partial synthesis of phæoporphyrin-*a*<sub>5</sub> and phylloerythrin. H.

FISCHER and H. KELLERMANN (Annalen, 1936, 524, 25—30; cf. A., 1935, 1382).—*iso*Chlorin- $e_4$  Me<sub>2</sub> ester is converted by protracted hydrogenation (Pd in AcOH) with subsequent re-oxidation of any leuco-compound formed into *isochlorophorphyrin-e<sub>4</sub>* Me<sub>2</sub> ester (I) and thence into the *hæmin* (II), C<sub>35</sub>H<sub>35</sub>O<sub>4</sub>N<sub>4</sub>FeCl, m.p. 289°, from which Fe could be removed only with difficulty. The product obtained from (II), CHCl<sub>3</sub>·OEt, and SnBr<sub>4</sub> is transformed by conc. H<sub>2</sub>SO<sub>4</sub> into 9-hydroxydeoxophæorphyrin- $a_5$  (III), m.p. 282°. The Me<sub>2</sub> ester of (III) is oxidised by CrO<sub>3</sub> in AcOH to phæorphyrin- $a_5$  Me<sub>2</sub> ester, m.p. 281°. (I) is converted by Br in AcOH into 6-bromoisochlorophorphyrin- $e_4$  Me<sub>2</sub> ester, m.p. 249°, which passes at 252° into phylloerythrin. H. W.

Chlorophyll. LXXI. Mesopurpurin, vinyl-chlorin, and their derivatives. H. FISCHER, K. HERRLE, and H. KELLERMANN (Annalen, 1936, 524, 222—250).—To distinguish between H<sub>2</sub>-derivatives in which the atoms are added to the vinyl group and those in which they are added to the porphin nucleus it is proposed to introduce the term phorbin, corresponding with A, for the fundamental

nucleus of chlorophyll. Phorbin derivatives with Et at 2 receive the prefix "meso." The open form obtained by removal of the *isocyclic* ring, B, is termed chlorin, the names thus coinciding with those of the older nomenclature. With purpurins and rhodins it is proposed where necessary to use the prefix "meso" to denote the saturation of the vinyl group, thus causing a change of nomenclature among synthetic phyllo-, pyrro-, and rhodo-chlorins. The use of "meso" for porphyrins is not contemplated since it would be required for nearly all known derivatives and the unsaturated substance when known are therefore to be called vinyl-rhodo-, -phyllo-, etc.

Phæophorbide- $a$  is hydrogenated (Pd in COMe<sub>2</sub>) to mesophæophorbide- $a$  which, in C<sub>5</sub>H<sub>5</sub>N-Et<sub>2</sub>O, is transformed by KOH-PrOH into mesopurpurin-7

(I), the Me ester (II), m.p. 215°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> +210° in COMe<sub>2</sub>, of which passes when heated above its m.p.

or boiled with C<sub>5</sub>H<sub>5</sub>N into rhodoporphyrin Me<sub>2</sub> ester; as by-product, *mesopurpurin-18* (III), m.p. 266°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> +1210° in 25% HCl, is obtained. When heated at about 290° (III) passes into rhodoporphyrin- $\gamma$ -carboxylic anhydride ester, m.p. 256°, [ $\alpha$ ]  $\pm 0^\circ$ , further identified by successive hydrolysis and treatment with CH<sub>2</sub>N<sub>2</sub>, whereby the Me<sub>2</sub> ester, m.p. 252°, is obtained. Under similar conditions (III) is transformed into *mesochlorin-p<sub>6</sub>* Me<sub>2</sub> ester, m.p. 201°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> +334° in COMe<sub>2</sub>. When heated with KOH in PrOH (I) loses the ·CO·CO<sub>2</sub>H residue and passes into *mesorhodochlorin* (IV), C<sub>32</sub>H<sub>36</sub>O<sub>4</sub>N<sub>4</sub>, m.p. (indef.) 275°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -364° in COMe<sub>2</sub> (Cu salt, m.p. 298°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -676° in COMe<sub>2</sub>), which affords rhodoporphyrin when heated at 250° or treated with HI, PhOH, or (·CH<sub>2</sub>·CO<sub>2</sub>H)<sub>2</sub> and *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>; the corresponding Me<sub>2</sub> ester (Cu salt, m.p. 196°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -242° in COMe<sub>2</sub>) has m.p. 176°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -299° in COMe<sub>2</sub>. During the thermal conversion of chlorins into porphyrins H<sub>2</sub> does not appear to be liberated, but pyrrole is produced. (IV) passes in boiling AcOH into *mesopyrrochlorin*, C<sub>31</sub>H<sub>34</sub>O<sub>4</sub>N<sub>4</sub>, m.p. 229°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -536° in COMe<sub>2</sub> (Me ester), converted when heated at 229° or treated with Cu(OAc)<sub>2</sub>-AcOH-air into pyrroporphyrin, also obtained by means of KOH-MeOH.

The chlorin- $f$  Me<sub>2</sub> ester of Conant *et al.* (A., 1931, 368), now designated *rhodochlorin* Me<sub>2</sub> ester, has m.p. 207°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -458° in COMe<sub>2</sub>. It is unchanged when heated above its m.p., or treated with boiling C<sub>5</sub>H<sub>5</sub>N or with (·CH<sub>2</sub>·CO<sub>2</sub>H)<sub>2</sub> and *m*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> or PhOH, but is converted by HI into rhodoporphyrin and by mild alkaline degradation or by Cu(OAc)<sub>2</sub>-AcOH-air into  $\psi$ -verdroporphyrin. It readily adds CHN<sub>2</sub>·CO<sub>2</sub>Et giving the product, C<sub>37</sub>H<sub>42</sub>O<sub>6</sub>N<sub>4</sub>, m.p. 198°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -302° in COMe<sub>2</sub>, which is isomerised by HI in AcOH to "*D.E.E.*- $\psi$ -verdroporphyrin ester," m.p. 244°. Free rhodochlorin in C<sub>5</sub>H<sub>5</sub>N is transformed by boiling AcOH into pyrro- and rhodo-porphyrin and *pyrrochlorin* (V), C<sub>31</sub>H<sub>34</sub>O<sub>2</sub>N<sub>4</sub>, m.p. 220°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -417° in COMe<sub>2</sub>, which absorbs 2 H and adds CHN<sub>2</sub>·CO<sub>2</sub>Et. It is converted by Cu(OAc)<sub>2</sub>-AcOH-air or by KOH-MeOH-air followed by CH<sub>2</sub>N<sub>2</sub> into *vinylpyrroporphyrin* Me ester, m.p. 244°, which is hydrogenated (Pd-COMe<sub>2</sub>) to pyrroporphyrin. Treatment of 2-deethylvinylpyrroporphyrin Me ester with CHN<sub>2</sub>·CO<sub>2</sub>Et causes displacement of the spectrum towards the blue. (V) has therefore the annexed structure. The stability of numerous chlorin, por-

phyrin, and purpurin derivatives towards Cu(OAc)<sub>2</sub>-AcOH-air has been investigated.

Phæopurpurin-7 is converted by HCl-MeOH at 0° into *purpurin* Me<sub>2</sub> ester, m.p. 178°. Mesochlorin- $e_6$  passes above its m.p. into mesophyllochlorin, m.p. 147°, [ $\alpha$ ]<sub>690-730</sub><sup>20</sup> -392° in COMe<sub>2</sub>, the ester of which

is converted by Br in  $\text{CHCl}_3$ -AcOH into the compound,  $\text{C}_{33}\text{H}_{38}\text{O}_2\text{N}_4\text{Br}_2$ , m.p.  $150^\circ$ ,  $[\alpha]_{\text{D}}^{20} -580^\circ$  in  $\text{COMe}_2$ .

H. W.

**Chlorophyll. LXXII.** Isomerism between chlorin- $p_6$  and  $\psi$ -chlorin- $p_6$  and their derivatives. Elucidation of the pyrrole structure of ring III of chlorophyll. H. FISCHER and K. KAHR (Annalen, 1936, 524, 251—268).—Treatment of mesophaeophorbide- $a$  in 1% NaOH with air at  $50^\circ$  and of the product with  $\text{CH}_2\text{N}_2$  gives meso- $\psi$ -chlorin  $Me$  ester, m.p.  $190^\circ$   $[\alpha]_{\text{D}}^{20} -168^\circ$  in  $\text{COMe}_2$ . Whereas chlorin- $p_6$  (I) and mesochlorin- $p_6$  are readily converted into their anhydrides, the change can be effected in the  $\psi$ -series to a minimal degree only in the case of the vinyl compound and not at all with the meso-derivative. The only possible explanation lies in the assumption that the two "superfluous" H atoms are attached to  $\text{C}_{(5)}$  and  $\text{C}_{(6)}$ , thus leading to the constitutions A and B for  $\psi$ -chlorin- $p_6$  (II) and (I).

(I) and (II) are transformed by HI into different rhodoporphyrin- $\gamma$ -carboxylic acids; the  $\text{Me}_3$  ester of that derived from (I) is transformed by conc.  $\text{H}_2\text{SO}_4$  into the green rhodoporphyrin- $\gamma$ -carboxylic anhydride whereas that from (II) gradually suffers total decomp. The results are explained by assuming the formation of a double linking between  $\text{C}_{(5)}$  and  $\text{C}_{(6)}$  in the one case and a wandering of the double linkings in the second instance. Similar relationships obtain between derivatives of (I) and (II). Thus *D.E.E.*-phaeophorbide- $a$  (III) is converted by  $\text{KOH}$ - $\text{PrOH}$  into *D.E.E.*-phaeopurpurin-18 (III) ( $Me$  ester,  $\text{C}_{38}\text{H}_{38}\text{O}_7\text{N}_4$ , m.p.  $211^\circ$ ,  $[\alpha]_{\text{D}}^{20} +104^\circ$  in  $\text{COMe}_2$ ) and *D.E.E.*-phaeopurpurin-7 (V) ( $Me_4$  ester,  $\text{C}_{40}\text{H}_{44}\text{O}_8\text{N}_4$ , m.p.  $195^\circ$ ,  $[\alpha]_{\text{D}}^{20} +303^\circ$  in  $\text{COMe}_2$ ), the former of which is transformed by  $\text{KOH}$ - $\text{MeOH}$  into *D.E.E.*-chlorin- $p$  (V) ( $Me$  ester  $\text{C}_{38}\text{H}_{44}\text{O}_8\text{N}_4$ , m.p.  $220^\circ$ ,  $[\alpha]_{\text{D}}^{20} +411^\circ$  in  $\text{COMe}_2$ ), re-convertible into (IV). Under the action of  $\text{NaOH}$ -air, (III) passes into *D.E.E.*- $\psi$ -chlorin- $p_6$  (VII) ( $Me$  ester, m.p.  $191^\circ$ ,  $[\alpha]_{\text{D}}^{20} -208^\circ$  in  $\text{COMe}_2$ ), also obtained by addition of  $\text{CHN}_2\cdot\text{CO}_2\text{Et}$  to  $\psi$ -chlorin- $p_6$  ester). Isomerisation of (VI) by colourless HI in AcOH at  $60^\circ$  leads to *D.E.E.*-rhodoporphyrin- $\gamma$ -carboxylic acid ( $Me_4$  ester, m.p.  $232^\circ$ ), whereas (VII) gives an isomeric  $Me_4$  ester, m.p.  $232^\circ$  (mixed m.p.  $217^\circ$ ). (IV) passes at  $280$ — $290^\circ$  into *D.E.E.*-rhodoporphyrin- $\gamma$ -carboxylic anhydride ( $Me_2$  ester, m.p.  $204^\circ$ ). (V) is transformed by boiling  $\text{C}_5\text{H}_5\text{N}$  into *D.E.E.*- $\psi$ -verdoporphyrin, m.p.  $246^\circ$ , which is unchanged by colourless HI in AcOH at  $60^\circ$ . Treatment of (III) with  $\text{KOH}$ - $\text{MeOH}$ - $\text{C}_5\text{H}_5\text{N}$ - $\text{MgO}$  at  $160^\circ$  affords *D.E.E.*-phyllorophyrin ( $Me$  ester, m.p.  $207.5^\circ$ ), whereas *D.E.E.*-pyrro- ( $Me$  ester, m.p.  $187^\circ$ ) and *D.E.E.*-rhodo-porphyrin ( $Me$  ester, m.p.  $245^\circ$ )

are derived from (III) and  $\text{KOH}$ - $\text{MeOH}$ - $\text{C}_5\text{H}_5\text{N}$  at  $185^\circ$  and  $125^\circ$ , respectively.

H. W.

**Chlorophyll. LXXIII.** New ring fission of phaeophorbide- $a$  and phaeoporphyrin- $a_5$ . H. FISCHER and S. GOEBEL (Annalen, 1936, 524, 269—284; cf. A., 1935, 362).—Treatment of phaeoporphyrin- $a_5$  (I) with  $\text{Mg}$ - $\text{MgEtBr}$  in  $\text{MeOH}$ - $\text{C}_5\text{H}_5\text{N}$  yields phaeoporphyrin- $a_5$ -phyllin (II),  $\text{C}_{35}\text{H}_{34}\text{O}_5\text{N}_4\text{Mg}$ , transformed by  $\text{CH}_2\text{N}_2$  in  $\text{Et}_2\text{O}$  into the  $Me_2$  ester, decomp. about  $220$ — $310^\circ$ , and by  $\text{CHMeN}_2$ + $\text{EtOH}$  into the  $Et_2$  ester (III), decomp. about  $220$ — $310^\circ$ . (III) is decomposed by 10%  $\text{HCl}$  to phaeoporphyrin- $a_5$   $Et_2$  ester (IV), m.p.  $272^\circ$ ; with  $\text{NH}_2\text{OH}$  it gives an oxime, whence the oxime of (IV) and ultimately (I); with  $\text{Ba(OH)}_2$  it gives chloroporphyrin- $e_6$ , identified as the tri-ester, m.p.  $242^\circ$ . The catalytic hydrogenation ( $\text{PtO}_2$  in dioxan) of (II) and of ethylchlorophyllide (improved prep.) is described.  $\text{Mg}$  is introduced similarly into phylloerythrin (V) giving the substance,  $\text{C}_{34}\text{H}_{34}\text{O}_3\text{N}_4\text{Mg}$ , which could not be obtained by decarboxylation of (II) in boiling  $\text{C}_5\text{H}_5\text{N}$ . The successful introduction of  $\text{Mg}$  into phaeophytin- $a$  necessitates the addition of phytol which could not be satisfactorily removed. Methylphaeophorbide- $a$  in  $\text{NH}_2\text{Me}$ - $\text{COMe}_2$  at room temp. affords the methylamide (VI), m.p.  $234^\circ$ , whereas  $\text{NH}_3$  in  $\text{C}_5\text{H}_5\text{N}$  gives the corresponding amide, m.p.  $195^\circ$ . Treatment of phaeophorbide- $a$  with  $\text{NH}_3$ - $\text{MeOH}$  and of the product with  $\text{CH}_2\text{N}_2$  affords a substance, m.p.  $139$ — $162^\circ$ , degraded by HI to chloroporphyrin- $e_6$  6-amide, m.p.

$278^\circ$ , identical with the product obtained from (I); it is transformed by  $\text{PhOH}$  at  $160^\circ$  into (I), by anhyd.  $\text{H}_2\text{C}_2\text{O}_4$  or 20%  $\text{HCl}$  at  $80^\circ$  (V), and by 33%  $\text{HCl}$ - $\text{MeOH}$  into chloroporphyrin- $e_4$  and - $e_6$ . (I) and  $\text{NHPh}\cdot\text{NH}_2$  or  $\text{NH}_2\text{Ph}$  give the corresponding phenylhydrazide ( $Me$  ester, m.p.  $259^\circ$ ) and (?) anilide. Phaeophorbide- $a$ , suspended in  $\text{MeOH}$ , is converted by  $\text{COCl}_2$  into a mixture of methylphaeophorbide- $a$  and chlorin- $e_6$  tri-ester, the latter being exclusively obtained when it is treated with 1%  $\text{KOH}$ - $\text{MeOH}$  in presence of  $\text{C}_5\text{H}_5\text{N}$ .

[With HAARER.] Passage of  $\text{COCl}_2$  through a suspension of (I) and geraniol in  $\text{CHCl}_3$  gives the corresponding geranyl ester,  $\text{C}_{45}\text{H}_{52}\text{O}_5\text{N}_4$ , m.p.  $194^\circ$ ; the corresponding menthyl, m.p.  $254^\circ$ , bornyl, m.p.  $243^\circ$  after softening, and dimethylaminoethyl, m.p.  $247^\circ$  (decomp.), esters are obtained similarly.

**Fluorescence of the porphyrins.**—See this vol., 1048.

**Optical absorption of porphyrins. VI.** See this vol., 1178.

**Colour reaction of copper and urobilin.**—See this vol., 1221.

**Spirographis-haemin.** H. FISCHER and C. VON SEEMANN (Angew. Chem., 1936, 49, 461—462).—*Spirographis*-haemin (I) (A., 1932, 292) gives spectrum

displacements suggesting the presence of  $\cdot\text{CH}:\text{CH}_2$ . Interaction with  $\text{CHN}_2\cdot\text{CO}_2\text{Et}$  (II) causes, however, a displacement towards the red, but as Warburg's oxime (*loc. cit.*) can be converted into a nitrile, the presence of a CHO (responsible for this anomalous behaviour) is suggested, and is confirmed by conversion of the latter into  $\text{CO}_2\text{H}$ . When the product from (I) and (II) is treated with  $\text{NH}_2\text{OH}$ , a spectrum displaced towards the blue is observed. Catalytic hydrogenation of (I) gives 1 : 2 : 3 : 5 : 8-pentamethyl-4-ethylporphin-6 : 7-dipropionic acid (A., 1930, 1450),  $\cdot\text{CHO}$  and  $\cdot\text{CH}:\text{CH}_2$  being converted into Me and Et, respectively. The resorcinol-melt of (I) yields deuterohæmin-IX-ester (deuteroporphyrin-IX-ester)

(A., 1928, 1385). (I) is thus the Fe derivative of 2-aldehyde-1 : 3 : 5 : 8-tetramethyl-4-vinylporphin-6 : 7-dipropionic acid, and has the annexed structure. (Cf. also this vol., 1271.) E. W. W.

**Local anæsthetics containing the morpholine ring. III. Esters of 2-alkoxycinchonic acids.** J. H. GARDNER and W. M. HAMMEL (J. Amer. Chem. Soc., 1936, 58, 1360—1361; cf. A., 1933, 960).—2-Chloroquinoline-4-carboxylic acid and  $\text{AlkOH}\cdot\text{NaOAlk}$  give 2-methoxy-, 2-ethoxy-, m.p. 142–2–143.8° (lit. 145–146°), 2-n-propoxy-, m.p. 138–139.4° (lit. 136°), and 2-n-butoxy-, m.p. 96.6–97.6° (lit. 111°), -quinoline-4-carboxylic acids [*chlorides*, m.p. 45.6–46.5°, 86–86.5°, 54–55°, and 35.5–37.5°, respectively;  $\beta$ -4-morpholine-ethyl esters, m.p. —, 44–46°, — (*hydrochlorides*, m.p. 198–199°, 147°, 150.6–151.2°, and 150.5–151.4°, respectively);  $\gamma$ -4-morpholinepropyl esters, m.p. —, 57–58°, — (*hydrochlorides*, m.p. 155–160°, 157°, 174.7–175.6°, and 149.2–149.6°, respectively)]. All m.p. are corr. The ester hydrochlorides are local anæsthetics.

H. B.

**N-p-Aminophenylmorpholine and naphthylaminophenylmorpholine.**—See B., 1936, 876.

**Aliphatic polyamines. II.** J. VAN ALPHEN (Rec. trav. chim., 1936, 55, 669–674; cf. this vol., 999).—When crude 2-phenyl-1 : 3-di-( $\beta$ -benzylidene-aminoethyl)tetrahydroglyoxaline is reduced with Na-EtOH and the resulting crude oily  $(\text{CH}_2\text{Ph})_2$  derivative is heated with EtOH-HCl, there are formed PhCHO and NN'-di-( $\beta$ -benzylaminoethyl)ethylenediamine, (anhyd.) an oil and  $+\text{H}_2\text{O}$ , m.p. 58° [*tetrahydrochloride*, m.p. 250–290° (decomp.), -*picrate*, m.p. 209°, and -*oxalate*, m.p. 270–280° (decomp.)];  $(\text{NO})_4$ , m.p. 136°, Bz, m.p. 196°, *tetra-phenylcarbamide*, m.p. 194°, and -*phenylthiocarbamide* derivative, m.p. 197°. This base with  $\text{CS}_2$  gives s-di-(2-thio-3-benzyltetrahydroquinazolin-1-yl)ethane, m.p. 167°, with the appro-

priate aldehyde in EtOH yields s-di-(2-phenyl-, m.p. 181°, -2-p-anisyl-, m.p. 165°, -(2-3' : 4'-methylenedioxyphenyl-, m.p. 170°, and -(2-2'-furfuryl-3-benzyltetrahydroquinazolin-1-yl)ethane, m.p. 142°, and with the  $\text{NaHSO}_3$  compound of  $(\text{CHO})_2$  in hot  $\text{H}_2\text{O}$  gives a cherry-red colour. R. S. C.

**Reactions of methylene derivatives containing cyanide, thiocyanate, or sulphonyl radicals.** C. E. GROTHAUS and F. B. DAINS (J. Amer. Chem. Soc., 1936, 58, 1334–1336).—The reactivity of the  $\text{CH}_2$  in  $\text{C}_6\text{H}_4\text{R}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CN}$  ( $\text{R}=\text{H}$ , *p*-Br) (and  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CN}$ ) resembles that of  $\text{CH}_2\cdot\text{Bz}\cdot\text{CO}_2\text{Et}$  and is  $>$  that of  $\text{COPh}\cdot\text{CH}_2\cdot\text{CNS}$  and still  $>$  that of  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_2\cdot\text{CH}_2\cdot\text{COPh}$ . Phenacyl cyanide (*CHPh*, m.p. 85°, and *p*-dimethylaminoanilo-, m.p. 128°, derivatives) and  $\text{NHPh}\cdot\text{CH}\cdot\text{NPh}$  (I) in xylene at 120° give  $\alpha$ -anilino- $\beta$ -cyano- $\beta$ -benzoylthiophene, m.p. 159°; the  $\alpha$ -o-, m.p. 167°, and -*p*-, m.p. 185°, -*chloro*-,  $\alpha$ -*p*-bromo-, m.p. 205°,  $\alpha$ -o-ethoxy-, m.p. 138°,  $\alpha$ -*p*-phenoxy-, m.p. 135°, and  $\alpha$ -*p*-phenyl- (II), m.p. 161°, -anilino-derivatives are similarly obtained using the appropriate diarylformamidine. The above ethylenes [except (II)] with  $\text{NH}_2\text{OH}$ ,  $\text{N}_2\text{H}_4$ , and  $\text{NHPh}\cdot\text{NH}$ , in EtOH give 5-imino-4-benzoylisooxazole, m.p. 154°, 4-cyano-3-phenylpyrazole, m.p. 134°, and 4-cyano-1 : 5-diphenylpyrazole, m.p. 182° [hydrolysed (conc. EtOH-KOH) at 160–170° to the 4-carboxylic acid, m.p. 173°], respectively. 1 : 3-Diphenyl-4-*p*-bromoanilino-methylene-5-pyrazolone, m.p. 184°, is obtained by fusion of 1 : 3-diphenyl-5-pyrazolone with di-*p*-bromophenylformamidine. *p*-Bromophenacyl cyanide, m.p. 159° (from the chloride and NaCN in EtOH), and (I) at 150° afford  $\alpha$ -anilino- $\beta$ -cyano- $\beta$ -*p*-bromobenzoylthiophene, m.p. 143°; this and the  $\alpha$ -*p*-bromoanilino-derivative, m.p. 209°, with  $\text{NH}_2\text{OH}$ ,  $\text{N}_2\text{H}_4$ , and  $\text{NHPh}\cdot\text{NH}$  give 5-imino-4-*p*-bromobenzoylisooxazole, m.p. 195°, 4-cyano-3-*p*-bromophenylpyrazole, m.p. 195°, and 4-cyano-1-phenyl-5-*p*-bromophenylpyrazole, m.p. 212°, respectively. Phenacyl thiocyanate and (I) in xylene at 160° afford 2-imino-5-benzoyl-3-phenyl-2 : 3-dihydrothiazole, m.p. 257°, probably by rearrangement of the intermediate  $\alpha$ -anilino- $\beta$ -thiocyano- $\beta$ -benzoylthiophene; the 3-*p*-chloro-, m.p. 204°, and -*p*-bromo-, m.p. 214°, -phenyl derivatives are obtained similarly. Phenacyl *p*-tolyl sulphone (*CHPh* derivative, m.p. 142°; phenylhydrazone, m.p. 188°) and (I) in xylene at 180–190° give  $\alpha$ -anilino- $\beta$ -benzoyl- $\beta$ -*p*-toluenesulphonylthiophene (III), m.p. 208° [ $\alpha$ -o-, m.p. 187°, and -*p*-, m.p. 217°, -*chloro*- and  $\alpha$ -*p*-bromo- (IV), m.p. 210°, -anilino-derivatives]. (III) and (IV) with  $\text{NHPh}\cdot\text{NH}$  give 4-*p*-toluenesulphonyl-1 : 5-diphenylpyrazole, m.p. 164°; no reaction occurs with  $\text{NH}_2\text{OH}$  or  $\text{N}_2\text{H}_4$ .  $\alpha$ -Anilino- $\beta$ -cyano- (V), m.p.  $>260^\circ$ , and - $\beta$ -carbethoxy-, m.p. 114–115°, - $\beta$ -*p*-nitrophenylthiophenes are formed from (I) and  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CN}$  and  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ , respectively. (V) does not react with  $\text{NH}_2\text{OH}$ .

H. B.

**Arylaminomethylbenzthiazyl sulphides.**—See B., 1936, 849.

**By-products of thiolbenzthiazole synthesis.** W. COCKER (J.S.C.I., 1936, 55, 228 $\pi$ ).—Benzthiazole is an impurity in technical thiolbenzthiazole (I) prepared from  $\text{NH}_2\text{Ph}$ ,  $\text{CS}_2$ , and S under certain con-

ditions. It is largely responsible for the usually unpleasant odour of (I). It forms well-defined crystals which hydrolyse in  $H_2O$ .

**Thiolbenzthiazole.** F. M. HAMER (Chem. and Ind., 1936, 682; cf. preceding abstract).—Benzthiazole has a not unpleasant odour resembling that of quinoline. H. W.

**5-Chloro- and 5-bromo-1-methylbenzthiazole and certain dyes prepared from them.** B. BEILSEN and (Miss) F. M. HAMER (J.C.S., 1936, 1225—1231).—**5-Bromo-1-methylbenzthiazole**, m.p. 86—87° (cf. Bogert and Naiman, A., 1935, 1386), obtained by oxidation of 4-bromothioacetanilide, gives an *ethobromide*, m.p. 197°, *etho-p-toluenesulphonate*, and *ethiodide* (I), m.p. 214° (decomp.). The following dyes have been prepared from (I), the *ethiodide*, m.p. 239° (decomp.), of 5-chloro-1-methylbenzthiazole, and other salts: **5:5'-dichloro-**, m.p. 288°, and **5:5'-dibromo-2:2'-diethylthiacyanine iodide**, m.p. 286°; **5-chloro-**, m.p. 287°, and **5-bromo-2:1'-diethyl-2'-cyanine iodide**, m.p. 278—279°; **5-chloro-**, m.p. 250°, and **5-bromo-2:2'-diethylthia-1'-cyanine iodide**, m.p. 253°; **5:5'-dichloro-iodide**, m.p. 292°, and **5:5'-dibromo-2:2'-diethylthiacarbocyanine bromide**, m.p. 283°; **5:5'-dichloro-iodide**, m.p. 303°, and **5:5'-dibromo-8-methyl-2:2'-diethylthiacarbocyanine bromide**, m.p. 280°; **5:5'-dichloro-**, m.p. about 258°, and **5:5'-dibromo-2:2':8-triethylthiacarbocyanine iodide**, m.p. 273°; **5:5'-dichloro-**, m.p. 270°, and **5:5'-dibromo-8-phenyl-2:2'-diethylthiacarbocyanine iodide**; **5:5'-dichloro-**, m.p. 278°, and **5:5':9-trichloro-2:2'-diethylthiacarbocyanine iodide**, m.p. 267°; **5:5'-dibromo-2:2'-diethylthiacarbocyanine p-toluenesulphonate**, m.p. 230°; **5:5':9-tribromo-2:2'-diethylthiacarbocyanine bromide**, m.p. 228°; **5:5'-dichloro-2:2'-diethylthiacarbocyanine iodide**, m.p. 227°; and **5:5'-dibromo-2:2'-diethylthiacarbocyanine p-toluenesulphonate**, m.p. about 184°. The absorption spectra of the compounds have been examined. M.p. of the dyes are also decomp. points.

F. R. S.

**Thiazoles obtained by direct thiocyanogenation.** R. Q. BREWSTER and F. B. DAINS (J. Amer. Chem. Soc., 1936, 58, 1364—1366).—Treatment of  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ , **3:4:1-NO<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>Me·NH<sub>2</sub>**, *m*-4-xylylene, **2:4:1-C<sub>6</sub>H<sub>3</sub>BrMe·NH<sub>2</sub>**, **4:2:1-NO<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>Me·NH<sub>2</sub>**,  $p\text{-C}_6\text{H}_4\text{Me·NH·Et}$ ,  $p\text{-C}_6\text{H}_4\text{Me·NH·CH}_2\text{Ph}$ , and  $p\text{-C}_6\text{H}_4\text{Me·NHMe}$  with  $\text{NH}_4\text{CNS}$  and Br in AcOH at <10° gives **5-nitro-1-imino-**, m.p. 252°, **4-nitro-1-imino-5-methyl-**, m.p. 257°, **1-imino-3:5-dimethyl-**, m.p. 140°, **3-bromo-1-imino-5-methyl-**, m.p. 211°, **5-nitro-1-imino-3-methyl-**, m.p. 280°, **1-imino-5-methyl-2-ethyl-** (I), m.p. 106° (*hydriodide*), **1-imino-2-benzyl-5-methyl-** (II), m.p. 80°, and **1-imino-2:5-dimethyl-** (III), m.p. 51° (*hydriodide*), **1:2-dihydrobenzthiazoles**, respectively. (I), (II), and (III) are also obtained by alkylation ( $\text{EtI}$ ,  $\text{CH}_2\text{PhCl}$ ,  $\text{MeI}$  in EtOH) of **1-imino-5-methyl-1:2-dihydrobenzthiazole** (IV).  $\text{NH}_2\text{Ph}$  and (IV) at 220° give **1-anilo-5-methyl-1:2-dihydrobenzthiazole**, m.p. 167°; **5-bromo-1-anilo-**, m.p. 188°, **1-p-tolylimino-5-methoxy-**, m.p. 160°, and **1-p-methoxy-**, m.p. 160°, **1-p-nitro-** (V), m.p. 272°, **1-p-acetamido-** (VI), m.p. 220°, and **1-p-chloro-anilo-** (VII), m.p. 197°, **5-**

**methyl-1:2-dihydrobenzthiazoles** are similarly prepared. (V) is reduced ( $\text{Sn}$ ,  $\text{HCl}$ ) to **1-p-aminoanilino-5-methylbenzthiazole**, m.p. 147°, also obtained by hydrolysis (15%  $\text{HCl}$ ) of (VI). (IV) heated at 270°/30 min. gives **di-(5-methyl-1-benzthiazolyl)amine**, m.p. 278°. (VI) and (VII) are also prepared from  $p\text{-C}_6\text{H}_4\text{Me·NH·CS·NH·C}_6\text{H}_4\text{R}$ -*p* ( $\text{R} = \text{NHAc}$  and  $\text{Cl}$ , respectively) and Br in  $\text{CHCl}_3$ ; similarly,  $p\text{-C}_6\text{H}_4\text{Me·NH·CS·NH·Et}$  gives **1-ethylimino-5-methyl-1:2-dihydrobenzthiazole**, m.p. 133°;  $p\text{-C}_6\text{H}_4\text{Me·NH·CS·NEt}_2$  affords **1-diethylamino-5-methylbenzthiazole**, an oil (picrate, m.p. 174°; *platini-chloride*);  $p\text{-C}_6\text{H}_4\text{Me·NH·CS·NH·CH}_2\text{Ph}$  furnishes **1-benzylimino-5-methyl-1:2-dihydrobenzthiazole**, m.p. 159°;  $p\text{-C}_6\text{H}_4\text{Br·NH·CS·NHPh}$  and  $(p\text{-C}_6\text{H}_4\text{Br·NH})_2\text{CS}$  yield **1-p-bromoanilo-**, m.p. 210°, and **5-bromo-1-p-bromoanilo-**, m.p. 256°, **1:2-dihydrobenzthiazole**, respectively. H. B.

**Cause of the red precipitate of bismuth salts with bismuthiols.** J. V. DUBSKÝ and A. OKAC (Chem. Obzor, 1935, 10, 83—84, 107—108, 123—125; Chem. Zentr., 1935, ii, 3383—3384).—Such ppts.

$$\begin{array}{c} \text{NH} \cdot \text{C} \cdot \text{S} \backslash \\ | \quad \text{S} < \quad \text{C} \cdot \text{S} \backslash \\ \text{N} = \text{C} \cdot \text{C} \cdot \text{C} \end{array} \text{Bi}$$
 are produced only when compounds of the type shown can be formed. H. N. R.

**Photochemical behaviour of thiodiazoline derivatives.** I. LIFSCHITZ and W. FROENTJES (Reo. trav. chim., 1936, 55, 753—760).—18 isomerides of **2:2:5-trisubstituted  $\Delta^4$ -1:3:4-thiodiazolines**,

$\text{CR} \begin{array}{c} \text{S} \\ \diagup \quad \diagdown \\ \text{N} \cdot \text{NR} \end{array}$ , are possible,  $\text{R}'$  is asymmetric.

When solutions of **3:5-diphenyl-2- $\alpha\beta\gamma\delta\epsilon$ -pentahydroxyamyl- $\Delta^4$ -1:3:4-thiodiazolines** (from galactose or arabinose and  $\text{SH·CPh·N·NHPh}$ ) are kept in the dark,  $\alpha$  slowly decreases, but never reaches 0. The ultraviolet absorption does not change, so that only racemisation occurs, being probably complete except for the sugar residue. Illumination greatly accelerates change of  $\alpha$  in MeOH, which falls to a min. (sometimes with change of sign), rises to a max., and then falls again, the changes being the more rapid the more dil. is the solution; this reaction is complex, probably consisting of racemisation, followed by oxidation of the  $\text{CH}_2\text{·OH}$  to  $\text{CHO}$  (development of reducing power), and decomp. of the heterocyclic nucleus. R. S. C.

**Antineuritic vitamin.** V. R. GREWE (Z. physiol. Chem., 1936, 242, 89—96; cf. this vol., 253).—Acetamidine (I) boiled in EtOH for several hr. with *Et* ethylenemalonate gives the *Et* ester (II) [*hydrochloride*, m.p. 205° (decomp.)] of **4-hydroxy-2:6-dimethyldihydropyrimidine-5-carboxylic acid**, m.p. 294° (decomp.). (II) in  $\text{C}_6\text{H}_5\text{N} + \text{CHCl}_3$  gives with 2 Br in  $\text{CHCl}_3$  at 0° the *Et* ester (III), m.p. 164°, of **4-hydroxy-2:6-dimethylpyrimidine-5-carboxylic acid**, m.p. 220° (decomp.) (*Me* ester, m.p. 160—162°), and (III) boiled with excess of  $\text{POCl}_3$  gives an oil which, with  $\text{NH}_3$  in EtOH at 80—100°, yields ***Et* 4-amino-2:6-dimethylpyrimidine-5-carboxylate**, m.p. 129°. (I) with ethoxymethylenemalononitrile gives **4-amino-5-cyano-2-methylpyrimidine**, m.p. 249°, which, treated in AcOH with gaseous  $\text{HCl}$  and then shaken with  $\text{H}_2$  in presence of  $\text{Pd-C}$ , yields **4-amino-2-methyl-5-aminomethylpyrimidine** (IV), identical with the

base  $C_6H_{10}N_4$  obtained from the vitamin by oxidation with  $BaMn_2O_8$ . When 4-amino-2-methyl-5-bromomethylpyrimidine [from (IV) by substitution of  $CH_2Br$  for  $CH_2NH_2$ ] in  $H_2O$  is saturated with  $NaHSO_3$ , treated with excess of  $SO_2$ , and heated at  $100^\circ$  for 2 hr. Br is replaced by  $SO_3H$  giving Williams' compound  $C_6H_9O_3N_3S$ , m.p.  $>350^\circ$  (this vol., 1159). W. McC.

**Structure of aneurin and thiochrome.** F. BERGEL and A. R. TODD (Nature, 1936, 138, 76).—A preliminary note (cf. Williams, A., 1935, 504; this vol., 1159). L. S. T.

**Synthesis of vitamin- $B_1$ .** R. R. WILLIAMS and J. K. CLINE (J. Amer. Chem. Soc., 1936, 58, 1504—1505).—6-Hydroxy-2-methyl-5-ethoxymethylpyrimidine (from Et  $\alpha$ -aldehydo- $\beta$ -ethoxypropionate and  $NH_2CMeNH$ ) is converted through the 6-Cl- into the 6- $NH_2$ -derivative, which with  $HBr$  gives 6-amino-2-methyl-5-bromomethylpyrimidine. This and 4-methyl-5- $\beta$ -hydroxyethylthiazole afford the bromide and thence the chloride (I), m.p.  $232-234^\circ$ , of vitamin- $B_1$ . (I) is identical (absorption; activity) with the natural chloride (II), m.p.  $246^\circ$  (mixed m.p.  $242-244^\circ$ ). (II) is often a mixture of stereoisomerides. (See preceding abstract.) H. B.

**Dihydrionicotyrine, 1-methyl-2-3'-pyridylpyrroline.** II. A. G. OOSTERHUIS and J. B. WIBAUT (Rec. trav. chim., 1936, 55, 727—729; cf. A., 1933, 77).—Dihydrionicotyrine (I) (*loc. cit.*) is resolved by way of the  $\alpha$ -bromocamphor- $\alpha$ -sulphonate [that of the d-base (II), m.p.  $115^\circ$ ], giving (II) (*dipicrate*, m.p.  $163-164^\circ$ ,  $[\alpha]_D^{25} +16^\circ$  in EtOH). (I) is thus 1-methyl-2-3'-pyridyl- $\Delta^3$ - or  $\Delta^4$ -pyrroline. Neither the dihydrionicotyrine nor the idonicotyrine of Pictet *et al.* (A., 1898, i, 688) could be prepared. R. S. C.

**Alkaloids of jaborandi leaves.** X. Synthesis and isomerisation of *r*-pilocarpine. N. A. PREOBRASHENSKI, A. M. POLJAKOVA, and V. A. PREOBRASHENSKI (Ber., 1936, 69, [B], 1835—1837).—*r*-Pilocypyl  $CHN_2$  ketone, m.p.  $113-113.5^\circ$  (corresponding 1-compound, m.p.  $105-107^\circ$ ), is converted by  $Ag_2O$  in abs. EtOH into Et *r*-homopilocate, b.p.  $116-118^\circ/0.5$  mm. (corresponding d-ester, b.p.  $106-108^\circ/0.01$  mm.,  $[\alpha]_D^{25} +64.26^\circ$  in  $C_2H_5Cl_4$ ; l-ester, b.p.  $115-117^\circ/0.5$  mm.,  $[\alpha]_D^{25} -94.33^\circ$  to  $[\alpha]_D^{20} -64.17^\circ$  in  $C_2H_5Cl_4$ ). *r*-Homopilocate acid, m.p.  $106-107^\circ$ , is converted through the corresponding chloride into *r*-homopilocypyl  $CHN_2$  ketone, m.p.  $60-62^\circ$  (corresponding d-ketone, m.p.  $80-81^\circ$ ), transformed by dry HCl in  $Et_2O$  into *r*-homopilocypyl  $CH_2Cl$  ketone (I), m.p.  $64-64.5^\circ$  (corresponding l-ketone, m.p.  $82.5-83.5^\circ$ ,  $[\alpha]_D^{25} -102.06^\circ$  in  $C_2H_5Cl_4$ ). (I) and  $C_6H_4(CO)_2NK$  in EtOH give *r*-homopilocypyl phthalimidomethyl ketone, m.p.  $142.5-143^\circ$ , hydrolysed by boiling HCl (1:1) to *r*-homopilocypyl  $CH_2NH_2$  ketone (*hydrochloride*, m.p.  $163-164^\circ$ ), which with KCNS affords *r*-2-thiopilocarpidine, m.p.  $203-204^\circ$ , oxidised to the corresponding base, whence *r*-pilocarpine nitrate (II), m.p.  $139-140^\circ$ . Treatment of (II) with NaOEt in EtOH gives *r*-isopilocarpine. H. W.

**$\alpha$ -Nicotine, 1-methyl-2-2'-pyridylpyrrolidine.** II. Relation between pharmacological action and chemical constitution in the nicotine group.

A. G. OOSTERHUIS and J. B. WIBAUT (Rec. trav. chim., 1936, 55, 729—736; cf. A., 1933, 1312).—The prep. of *dl*- $\alpha$ -nicotine (I) is improved. Previous data are confirmed (cf. A., 1934, 787); a small amount of a by-product (*picrate*, m.p.  $148^\circ$ ) is obtained. The pharmacological properties of (I) (mostly reported elsewhere) are detailed. (I) is less toxic than nicotine (II). Consideration of the action of other  $C_5H_5N$  derivatives shows that the lowering effect of (I) on blood-pressure as compared with the raising due to (II) is caused by the  $\alpha$ -position of the pyrrolidine nucleus in (I) and its  $\beta$ -position in (II). R. S. C.

**Cotarnine series.** VI. Condensation of cotarnine with carbonyl chloride. B. B. DEY and (Miss) P. L. KANTAM. VII. Action of sulphuric acid on cotarnine: formation of methylenebisphenol-betaine of 6:7-dihydroxy-8-methoxy-2-methyl-3:4-dihydroisoquinolinium hydroxide. B. B. DEY and T. K. SRINIVASAN (J. Indian Chem. Soc., 1936, 13, 281—283, 337—344).—VI. Cotarnine (I),  $COCl_2$ , and NaOH form cotarnomethylcarboxyl chloride, m.p.  $106^\circ$  (*anil*, m.p.  $132^\circ$ ), which could not be hydrolysed to the acid. It forms Et, m.p.  $100^\circ$  (*oxime*, m.p.  $129^\circ$ , and its *Ac* derivative, m.p.  $127^\circ$ ; *phenylhydrazone*, m.p.  $120^\circ$ ), and Me cotarnomethylcarboxylate, m.p.  $139^\circ$ . 5-Bromocotarnomethylcarboxyl chloride, m.p.  $142^\circ$  (*anil*, m.p.  $149^\circ$ ), similarly forms an Et ester, m.p.  $90^\circ$  (*oxime*, m.p.  $155^\circ$ ; *phenylhydrazone*, m.p.  $165^\circ$ ).

VII. (I) and 90%  $H_2SO_4$  at room temp. for 3 days give the methylenebisphenol-betaine of 6:7-dihydroxy-8-methoxy-2-methyl-3:4-dihydroisoquinolinium hydroxide ( $+H_2O$ ) (II), m.p.  $308^\circ$  (decomp.) [*dihydrochloride*, m.p.  $200^\circ$  (decomp.); *mono*-, m.p.  $222^\circ$ , and *dinitrate*, m.p.  $93^\circ$ ; *platinichloride* ( $+H_2O$ ), m.p.  $198^\circ$  (decomp.); *dipicrate*, m.p.  $230^\circ$  (decomp.); *monomethiodide* ( $+H_2O$ ), m.p.  $220^\circ$  (decomp.); *monomethiodide*, m.p.  $222^\circ$ ]. The monomethiodide and NaOH form (II), but demethylation (HI) of (II) yields the methylenebisphenol-betaine of 6:7:8-trihydroxy-2-methyl-3:4-dihydroisoquinolinium hydroxide, m.p.  $275^\circ$  (decomp.) [*dihydrochloride*, m.p.  $220^\circ$  (decomp.); *dinitrate*, m.p.  $195^\circ$  (decomp.)]. Methylation ( $Me_2SO_4$ ) of (II) leads to the methylenebisphenol-betaine of 7-hydroxy-6:8-dimethoxy-2-methyl-3:4-dihydroisoquinolinium hydroxide, m.p.  $268^\circ$  (decomp.) [*dihydrochloride*, m.p.  $191^\circ$  (decomp.); *dinitrate*, m.p.  $235^\circ$  (decomp.); *platinichloride*, m.p.  $248^\circ$  (decomp.); *picrate*, m.p.  $114^\circ$ ; *dimethiodide* (III), m.p.  $180^\circ$  (decomp.)]. (III) is reduced ( $Zn-H_2SO_4$ ) to methylenebis-6:7:8-trimethoxy-2-methyl-1:2:3:4-tetrahydroisoquinoline, m.p.  $201^\circ$ . F. R. S.

**Alkaloids of ergot.** VI. Ergometrine. S. SMITH and G. M. TIMMS (J.C.S., 1936, 1166—1169; cf. A., 1935, 1256).—Ergometrine (I), decomp.  $195-197^\circ$ ,  $[\alpha]_{D^{461}}^{25} +520^\circ$  in  $CHCl_3$ , forms a *hydrochloride*, decomp.  $175-180^\circ$ , *hydrobromide*, *perchlorate*, decomp.  $225^\circ$ , *nitrate*, decomp.  $235^\circ$ ,  $[\alpha]_{D^{461}}^{25} +361^\circ$  in  $H_2O$ , and *H sulphate*, decomp.  $250^\circ$ ; it has little or no pharmacological or clinical action. Hydrolysis of (I) and of ergometrine (II) with HCl affords *d*- $NH_2CHMeCH_2OH$  and of (I) with KOH-MeOH yields lysergic acid. (I) and (II) are interconvertible by acids or alkalis and it is suggested that physiological

activity may be dependent largely on the configuration of the lysergic acid group, although other forms of isomerism susceptible to facile reversibility cannot be excluded from consideration. F. R. S.

**New alkaloid and an acid salt from ergot, and an acid derived from the salt.** G. W. HOLDEN and G. R. DRIVER (Quart. J. Pharm., 1936, 9, 230—234).—During the manufacture of ergotamine, a phenolic alkaloid, *ergomonamine*,  $C_{19}H_{19}O_4N$ , m.p. 132—132.5° (*picrate*, m.p. 163—164°), has been obtained. From ergot, an acid *K salt*,  $C_7H_9O_{11}NK$  (?), has been isolated, from which the Ag salt gives *citergic acid*,  $C_6H_8O_{10}$ , m.p. 157—158° ( $Ac_4$  derivative, m.p. 128—129°); the acid is probably  $\alpha\beta\gamma$ -tetrahydroxypropane- $\alpha\beta\gamma$ -tricarboxylic acid. F. R. S.

**Ergot alkaloids. XI. Isomeric dihydrolysergic acids. Structure of lysergic acid.** W. A. JACOBS and L. C. CRAIG (J. Biol. Chem., 1936, 115, 227—238; cf. this vol., 742).—Ergotamine with  $H_2$ -PtO<sub>2</sub> in AcOH absorbs 1.8 H<sub>2</sub> to give an oily product, hydrolysed to  $\gamma$ -*dihydrolysergic acid* (I), decomp. 300—330°,  $[\alpha]_D^{25} + 32^\circ$  in  $C_6H_5N$ , the oily *Me* ester of which with Na-BuOH gives  $\gamma$ -*dihydrolysergol*, m.p. about 255° (decomp. from 234°),  $[\alpha]_D^{25} + 33^\circ$  in  $C_6H_5N$ . Ergotamine and ergine absorb 1.67 and 1.6 H<sub>2</sub>, respectively, to give oily products,  $[\alpha]_D^{25} + 382^\circ$  in  $CHCl_3$  and  $+332^\circ$  in MeOH, respectively, hydrolysed to (I). Ergotamine absorbs about 3 and ergotamine 1.6 H<sub>2</sub> (to give a product with  $[\alpha]_D^{25} - 140^\circ$  in  $CHCl_3$ ); hydrolysis of the products gives  $\alpha$ -*dihydrolysergic acid* (II) [obtained from lysergic acid (III) and not previously given the prefix], also obtained from ergometrine (IV). Hydrogenation of (III) gives a mixture of (I) and (II). The *Me* ester (V) of (II) with Na-BuOH gives  $\alpha$ -*dihydrolysergol*. *Me* lysergate mutarotates in hot MeOH (only oils were isolated), but (V) is stable; similarly dihydroergometrine does not mutarotate, whereas (IV) does. The ethylenic linking is thus involved in mutarotation. These and other facts are discussed on the basis of the annexed formula for (III). The positions of the CO<sub>2</sub>H and ethylenic linking

are uncertain but probable. Position 4 for the CO<sub>2</sub>H is improbable, because (III) sublimes largely unchanged. Mutarotation involves alternation of the ethylenic linking between positions 9—10, 10—5, and/or 4—5, or less probably permanent migration of this linking. R. S. C.

**Senecio alkaloids. III. Degradation of platynecine to heliotridane.** R. KONOVALOVA and A. OREKHOV (Ber., 1936, 69, [B], 1908—1913; cf. A., 1935, 764, 1387).—Platynecine (I) is converted by BzCl in  $C_6H_5N$  into *dibenzoylplatynecine* (*hydrochloride*, m.p. 228—230°), which could not be hydrogenated (PtO<sub>2</sub>). Monobenzoylplatynecine (II) is not dehydrated by P<sub>2</sub>O<sub>5</sub> in  $C_6H_6$  or boiling PhMe and is transformed by conc. H<sub>2</sub>SO<sub>4</sub> at room temp. into anhydroplatynecine (III). Gradual addition of SOCl<sub>2</sub> to (II) yields *monobenzoylplatynecine chloride* (IV),  $C_{15}H_{28}O_2NCl$ , m.p. 73—74° (*picrate*, m.p. 185—186°;

*picrolonate*, m.p. 198—199°; *hydrochloride*, m.p. 203—204°; *hydriodide*, m.p. 176—177°). (IV) retains Cl very firmly and is not affected by Zn dust and Mg powder with HCl, AcOH, or HI or by catalytic H (Pt or Pd). Alkaline reduction causes removal of Bz with production of (III). (IV) is indifferent to boiling quinoline. PCl<sub>3</sub>, POCl<sub>3</sub>, and PCl<sub>5</sub> dehydrate (I) exclusively whereas SOCl<sub>2</sub>, distilled over cottonseed oil, gives *platynecine dichloride* (V),  $C_8H_{13}NCl_2$ , m.p. 63—64° (*hydrochloride*, m.p. 186—187°; *picrate*, m.p. 205—206°), in very small yield. (V) is resistant to catalytic hydrogenation (Pt or Pd) but is converted by Na and EtOH to a mixture of saturated and unsaturated bases hydrogenated to heliotridane, b.p. 169—171°/750 mm.,  $[\alpha]_D - 52.91^\circ$  in EtOH.

H. W.

**Structure of aconitine.** W. FREUDENBERG (Ber., 1936, 69, [B], 1962—1965; cf. this vol., 618).—Aconitine (I) is converted by dry distillation with Ba(OH)<sub>2</sub> into NH<sub>2</sub>Et, identified as 2:4-dinitroethylaniline. Demethylation of (I) followed by treatment of the residue according to Willstätter and Utzinger gives EtI, which is not obtained similarly from oxonitine (II). (I) contains 3 active H, corresponding with 3 identified OH groups, whereas (II) contains 4. The additional H in (II) is therefore probably united to N and takes the place of Et in (I). The additional O in (II) indicates a vicinal CO and confers its lactam character on (II). Oxidation of (I) and (II) with CrO<sub>3</sub> gives 3 and 2 mols. of volatile acid, respectively (2 or 1 AcOH + 1 BzOH). Assuming (I) to have the mol. formula  $C_{34}H_{47}O_{11}N$ , its constitution may be resolved into  $C_{19}H_{19}(NEt)(OH)_3(OMe)_4(OAc)(OBz)$ . The fundamental base is therefore  $C_{19}H_{26}NH$ , and the fundamental hydrocarbon is  $C_{20}H_{30}$  contrasted with a paraffin  $C_{20}H_{42}$ . Determination of the no. of double linkings by catalytic micro-hydrogenations shows the presence of three in (I) and (II) but none in aconine (III). Therefore in (I) and (II) the Bz group is perhydrogenated and (III) does not contain a double linking. The H deficit in  $C_{20}H_{30}$  can therefore be explained only by assuming the presence of six perhydrogenated rings. H. W.

**Addition of organomagnesium halides to  $\psi$ -codeine types. II. Preparation of nuclear alkylated morphine derivatives.** L. SMALL, H. M. FITCH, and W. E. SMITH (J. Amer. Chem. Soc., 1936, 58, 1457—1463; cf. this vol., 490).—Dihydrothebaine (I) [prepared by reduction (H<sub>2</sub>, colloidal Pd, 3*N*-AcOH, little conc. HCl) of thebaine] added slowly (Soxhlet) to an excess of MgMeI gives the phenolic *methylidihydrothebainone* (II), m.p. 192—193°,  $[\alpha]_D^{25} - 20.5^\circ$  in EtOH [*hydrochloride*, m.p. (vac.) 283—285° (decomp.); *methiodide*, m.p. (vac.) 212—216°; *oxime*, m.p. (vac.) 244°; *Ac* derivative, m.p. 179—179.5°], and some of the phenolic *isomethylidihydrothebainone* (III), m.p. 168—168.5°,  $[\alpha]_D^{25} - 57^\circ$  in EtOH [*oxime*, m.p. (vac.) 191—192°; *Ac* derivative, m.p. 157—158°]. The production of (II) and (III) from (I) involves fission of the O ring, hydrolysis (probably during isolation) of the enol *Me* ether group at C<sub>6</sub>, and addition of Me (at ? C<sub>5</sub>, and C<sub>7</sub>). (II) and Br in AcOH followed by aq. NaOH give a little

*bromomethylidihydrothebainone*, m.p. (vac.) 207—208° (decomp.) [debrominated to (II)], and (mainly) *bromomethylidihydrocodeinone* (IV), m.p. 143.5—145°. Reduction ( $\text{H}_2$ , Pd, 2*N*-AcOH, KOAc) of (IV) gives *methylidihydrocodeinone*, m.p. 144—144.5°,  $[\alpha]_D^{20}$  -146.9° in EtOH [*methiodide*, m.p. (vac.) 246—248°; *enol acetate*, m.p. 191.5—194.5°], which condenses with  $\text{Et}_2\text{C}_2\text{O}_4$  in EtOH-NaOEt to a glyoxylic acid [*hydrochloride*], is reduced ( $\text{H}_2$ , PtO<sub>2</sub>, EtOH) to *methylidihydrocodeine* (V) (+ $\text{H}_2\text{O}$ ), m.p. 98—102°, m.p. (anhyd.) 85—88°,  $[\alpha]_D^{24}$  -84.8° in EtOH [*hydrochloride*, m.p. (vac.) 286—287°; *methiodide*, m.p. (vac.) 269—271°], and is demethylated (48% HBr) to *methylidihydromorphine*, m.p. (vac.) 243—245° (sinters at 235°),  $[\alpha]_D^{24}$  -140.7° in EtOH [*hydrochloride*, m.p. (vac.) 315—318° (decomp.)], which is reduced (Adams) to *methylidihydromorphine* (VI), m.p. 206—207°,  $[\alpha]_D^{24}$  -92.9° in EtOH [*hydrochloride*, m.p. (vac.) 316—317° (decomp.)]; *hydriodide*, m.p. (vac.) 289—291°. (VI), which could not be prepared by demethylation of (V), is methylated ( $\text{CH}_3\text{N}_2$ ) to (V). Bromoisomethylidihydrocodeinone [from (III) and Br in AcOH followed by aq. NaOH] is debrominated [as for (IV)] to *isomethylidihydrocodeinone*, m.p. 144—145°,  $[\alpha]_D^{24}$  -179.4° in EtOH (*enol acetate*, m.p. 123—124°), which appears to condense with  $\text{Et}_2\text{C}_2\text{O}_4$  (cryst. products not isolable). H. B.

**Strychnos alkaloids. LXXXIX. iso-Forms of dihydro-brucine and -strychnine and their benzylidene derivatives.** H. LEUCHS and A. DORNOW (Ber., 1936, 69, [B], 1838—1844).—Analyses of *isodihydrobrucine* I,  $[\alpha]_D^{20}$  -165° in abs. EtOH, after desiccation at 110° or 130°/15 mm., agree with  $\text{C}_{23}\text{H}_{28}\text{O}_4\text{N}_2$ ; it contains 1 active H (Zerevitinov) and its *Ac* derivative is passive towards MgMeI in PhOMe. The *hydrobromide*,  $[\alpha]_D^{20}$  -167°, and *methiodide*,  $[\alpha]_D^{15}$  -48.1° in 90% AcOH, are described. The base does not react with PhCHO in EtOH containing NaOEt. Oxidation of it by  $\text{Ba}(\text{MnO}_4)_2$  in  $\text{COMe}_2$  gives a substance,  $\text{C}_{23}\text{H}_{28}\text{O}_5\text{N}_2$ , decomp. 315°,  $[\alpha]_D^{15}$  +63.5° in  $\text{CHCl}_3$  (*hydrobromiae*, m.p. about 65°, or after desiccation, decomp. about 325°,  $[\alpha]_D^{20}$  +29° in  $\text{H}_2\text{O}$ ; *acetate*, m.p. 260—265° (decomp.),  $[\alpha]_D^{20}$  +40.8° in  $\text{CHCl}_3$ ), whereas  $\text{CrO}_3$  in 3.6*N*- $\text{H}_2\text{SO}_4$  transforms it into a compound, (?)  $\text{C}_{15}\text{H}_{20}\text{O}_5\text{N}_2$ . *isodihydrobrucine* II is transformed by PhCHO and NaOEt in EtOH into *isobenzylidenedihydrobrucine* (*methiodide*, m.p. 195° and 264°), where as *isodihydrobrucine* III (I) is isomerised to base I. (I) contains 1 active H (Zerevitinov) which is not present in its acetate. It affords a *hydrobromide*, decomp. >330° after darkening at 260°,  $[\alpha]_D^{20}$  +17.5°; it does not absorb H (Pt in 2*N*-AcOH), is stable towards  $\text{KMnO}_4$ , and is oxidised by  $\text{CrO}_3$  to a substance, (?)  $\text{C}_{16}\text{H}_{20}\text{O}_6\text{N}_2$ . *isodihydrostrychnine* (II) (*acetate*,  $[\alpha]_D^{20}$  +33.5° in 90% AcOH) contains 1 active H. It is transformed by PhCHO-EtOH-NaOEt into *isobenzylidenedihydrostrychnine*, m.p. 186°, and appears to be isomerised by NaOMe in MeOH at 100° to a substance,  $[\alpha]_D^{20}$  -110° in EtOH; oxidation with  $\text{KMnO}_4$  gives indefinite results. Treatment of the base with  $\text{Ba}(\text{MnO}_4)_2$  in warm  $\text{COMe}$ , possibly affords *isodihydrostrychnine* II, m.p. 248°,  $[\alpha]_D^{20}$  -48° to -60°. Hydrogenation of (II) gives a substance, m.p. 228°,  $[\alpha]_D^{20}$  -23.7° in 90%

AcOH, which contains 1 active H, gives a *methiodide*, m.p. about 310° (decomp.),  $[\alpha]_D^{20}$  -5° in 90% AcOH, and an *Ac* derivative (*perchlorate*, m.p. about 60°, decomp. 105°,  $[\alpha]_D^{20}$  -2.6° in AcOH); it does not condense with PhCHO. H. W.

**Emetine camphorsulphonate.** C. A. GRAU (Bull. Sci. pharmacol., 1935, 42, 452—456; Chem. Zentr., 1935, ii, 3676).—*Emetine d-camphorsulphonate* is therapeutically preferable to the hydrochloride.

H. N. R.

**South American curare.** F. W. FREISE (Pharm. Ztg., 1936, 81, 818—820; cf. this vol., 534).—Curare preps. (analytical data given) afford an alkaloid *macoubeine*,  $\text{C}_{22}\text{H}_{26}\text{O}_2\text{N}_2 \cdot 4\text{H}_2\text{O}$ , decomp. 185°,  $[\alpha]_D^{20}$  -55.5° in EtOH, containing 1 OMe, the toxic dose of which in various animals is 0.05—0.10 mg. per kg., the time of appearance of the symptoms being independent of the dose.

F. O. H.

**Arsonic acids of diphenylene oxide and diphenyl ether.** W. C. DAVIES and C. W. OTHERN (J.C.S., 1936, 1236—1239).—Mercuration of diphenylene oxide yields 1-acetoxymercuridiphenylene oxide, which with  $\text{CaCl}_2$  gives the 1-HgCl-compound, converted by  $\text{AsCl}_3$  into *diphenylene oxide-1-arsinic acid monohydrate*, m.p. 186—188° (decomp.). 2-Amino-diphenylene oxide hydrochloride on diazotisation and addition of  $\text{As}_2\text{O}_3$  gives *diphenylene oxide-2-arsinic acid monohydrate*, m.p. 385° (*Ba* salt); the -3-*acid monohydrate*, m.p. 213—214° (*Ba* salt), is similarly prepared and may also be obtained from diphenylene oxide and  $\text{AsCl}_3$  in *o*- $\text{C}_6\text{H}_4\text{Cl}_2$  with  $\text{AlCl}_3$ . *p*-Nitrodiphenyl oxide after reduction is converted into *p-phenoxyphenyl-arsinic acid*, m.p. 365°, which yields the -*dichloroarsine*, m.p. 66°; the arsine cannot be cyclised. The acid is brominated to *p-bromo-p-arsinodiphenyl ether*, m.p. 354—355° (*p-Cl*-compound, m.p. 375°, and its *Ba* salt).  $\text{AsMe}_2\text{I}$  and  $\text{Mg } p$ -bromodiphenyl ether give *p-phenoxyphenyldimethylarsine*, b.p. 189—190°/10 mm. (*methiodide*, m.p. 240°; *ethiodide*, m.p. 237°; *di-iodide*, m.p. 134°). *o*-Phenoxyphenyltrimethylarsonium iodide has m.p. 229—230°.

F. R. S.

**Organic arsenic compounds.**—See B., 1936, 908.

**Smooth conversion of compounds  $\text{HgRX}$  into compounds  $\text{HgR}_2$ .** H. GILMAN and M. M. BARNETT [and, in part, R. H. KIRBY] (Rec. trav. chim., 1936, 55, 563—566).—Compounds  $\text{HgRX}$  ( $\text{R}=\text{aryl}$ ) are converted rapidly and in excellent yield into  $\text{HgR}_2$  and Hg by  $\text{N}_2\text{H}_4$ ,  $\text{NH}_2\text{OH}$ , or  $\text{NH}_2\text{NH}\cdot\text{CO}\cdot\text{NH}_2$  (slowly) (or their salts with  $\text{Na}_2\text{CO}_3$ ) in hot EtOH. Good yields are also obtained with mixtures of  $\text{HgRX}$  and  $\text{HgR}_2$ . If R is alkyl, yields are less good; the yield is 90% with *N*-ethyl-2-acetoxymercuricarbazole. With  $\text{N}_2\text{H}_4$   $\text{PbPh}_2\text{Cl}$  gives slowly 74% of  $\text{PbPh}_4$ , also obtained from  $\text{PbPh}_2\text{Cl}_2$  in 53.5% yield with much of an amorphous substance.  $\text{SnPh}_3\text{Cl}$  and  $\text{SnPh}_3\text{I}$  with  $\text{N}_2\text{H}_4$  give a little  $\text{SnPh}_4$  and much  $\text{SnPh}_3\cdot\text{OH}$ .  $\text{SnPh}_2\text{I}_2$  gives a little  $\text{SnPh}_3\cdot\text{OH}$  and (?)  $\text{SnPh}_2\text{O}_2$ . The mechanism of the reaction is uncertain.

R. S. C.

**Phenyl mercurinitrates.**—See B., 1936, 825.

**Relative reactivities of organo-metallic compounds.** X. LITHIUM and magnesium [compounds]. H. GILMAN and M. LICHTENWALTER [and, in part, R. H. KIRBY]. XI. Grignard reagents. H. GILMAN, (MISS) E. L. ST. JOHN, (MISS) N. B. ST. JOHN, and M. LICHTENWALTER [and, in part, L. L. HECK]. XII. Competitive reactions of some compounds, RHal, with magnesium. (MISS) E. L. ST. JOHN and N. B. ST. JOHN (Rec. trav. chim., 1936, 55, 561—563, 577—585, 585—588; cf. this vol., 1004).—X.  $\text{MgPhBr}$  reacts slowly with  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CN}$  (3-8 hr.) and  $p\text{-NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{CN}$  (5-15 hr.) to give >90 and 60% of  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{COMe}$  and  $p\text{-NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{COMe}$ , respectively (cf. A., 1926, 914; 1904, i, 925). The only remaining qual. difference between Mg and Li compounds is thus reaction of the latter with olefines, and even the former may react slowly. Comparisons of Mg and Li compounds are carried out better using  $\text{Mg}\cdot\text{R}$  than  $\text{MgRHal}$ .  $\text{PhCN}$  reacts (to disappearance of the colour test) in 0.07 hr. with  $\text{LiMe}$  and 2.8 hr. with  $\text{MgMe}_2$ .

XI. The times of reaction (to disappearance of the colour test) of 41 Mg organohalides with  $\text{PhCN}$  are determined. There is a sharp differentiation of alkyl from the more reactive aryl groups and general (but not complete) parallelism with the ease of reaction of the Pb and Hg compounds, but none with other Grignard reactions. 2:4:6- $\text{C}_6\text{H}_3\text{Me}_3\cdot\text{MgBr}$  and  $\text{PhCN}$  give a ? ketimine, m.p. 260—261° (containing Br and N), hydrolysed to  $\text{C}_6\text{H}_4\text{Me}_3\cdot\text{COPh}$ . I accelerates many of the reactions and catalytic effects are also observed in some cases with  $\text{PbEt}_4$ ,  $\text{PhCl}$ ,  $\text{CuCl}$ ,  $\text{PhBr}$ , and xylene, but not  $\text{PhMe}$ . Mixed Grignard reagents behave as the sum of the individuals.  $\text{Et}_2$  fumarate and maleate react very fast with  $\text{MgBu}^+\text{Br}$  and  $\text{MgPhBr}$ .  $\text{EtOBz}$  and  $\text{COPh}$  react completely with 1 mol. of  $\text{MgPhBr}$  in 0.1 and 0.13 hr., respectively, but  $\text{EtOBz}$  reacts with 2 mols. only in 0.5 hr., and similar phenomena are observed in the stepwise and complete reaction of  $\text{PhOBz}$ ,  $\text{BzOH}$ , and  $\text{Bz}_2\text{O}$  with  $\text{MgPhBr}$ .

XII. Reaction of an alkyl halide with Mg accelerates the simultaneous reaction of an aryl halide, which may explain the usual catalytic effect of the former.  $m$ - and  $p$ - $\text{C}_6\text{H}_4\text{Br}_2$  react slightly,  $m$ - and  $p$ - $\text{C}_6\text{H}_4\text{Cl}_2$  much, faster than the corresponding  $o$ -compound under comparable conditions. R. S. C.

**Organoselenium compounds.** VI. S. KEMATSU, K. YOKOTA, and I. SATODA (J. Pharm. Soc. Japan, 1933, 53, 994—1046).— $\text{PhSeNa}$  and  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\text{Cl}$  give  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{SePh}$  in 25% yield. Treatment of the appropriate Grignard compound with Se affords *selenopyrocatechol O-Me ether* (I), b.p. 79—80°, *selenoresorcinol O-Me ether*, b.p. 81°, and *selenoquinol O-Me ether* (II), b.p. 78°, oxidised ( $\text{FeCl}_3$ ) to *bis-o*-, m.p. 90°,  $m$ -, m.p. 194°, and  $p$ -, m.p. 53.5°, *-methoxyphenyl diselenide*, respectively. Treatment of (I) with alkyl halides yields the following *O-Me selenoalkyl ethers* (III): *Me*, m.p. 30°; *Et*, b.p. 91—92°; *Pr*<sup>a</sup>, b.p. 102—103°; *Pr*<sup>β</sup>, b.p. 91—92°; *Bu*<sup>a</sup>, b.p. 106°; *Bu*<sup>β</sup>, m.p. 28.5°; *isoamyl*, b.p. 111°; *hexyl*, b.p. 131.5°. Corresponding (II) derivatives: *Me*, b.p. 93°; *Et*, b.p. 94.5°; *Pr*<sup>a</sup>, b.p. 99°; *Pr*<sup>β</sup>, b.p. 97.5°; *Bu*<sup>a</sup>, b.p. 116°; *Bu*<sup>β</sup>, b.p. 102.5°;

*isoamyl*, b.p. 107°; *hexyl*, b.p. 128°. (III) with  $\text{RMgI}$  yields the following *monoselenopyrocatechol selenoalkyl ethers*: *Me*, b.p. 53°; *Et*, b.p. 68.5°; *Pr*<sup>a</sup>, b.p. 81°; *Pr*<sup>β</sup>, b.p. 75°; *Bu*<sup>a</sup>, b.p. 93°; *Bu*<sup>β</sup>, b.p. 76°; *isoamyl*, b.p. 85°; *hexyl*, b.p. 103—104°. Corresponding *quinol derivatives*: *Me*, b.p. 108°; *Et*, b.p. 113°; *Pr*<sup>a</sup>, b.p. 116°; *Pr*<sup>β</sup>, b.p. 117°; *Bu*<sup>a</sup>, b.p. 123°; *Bu*<sup>β</sup>, b.p. 127°; *hexyl*, m.p. 35°. Methoxydiazonium chlorides couple with Na methoxyselenophenoxides to yield bis(methoxyphenyl) diselenides, which are demethylated by means of  $\text{RMgI}$ ; in this way the following *Ph<sub>2</sub> selenides* are prepared: *bis-m-hydroxy*-, m.p. 91°; *bis-m-methoxy*-, b.p. 169°/1 mm.; *bis-2-hydroxy*-, m.p. 126°; *bis-2-methoxy*-, m.p. 81°; *bis-2-ethoxy*-, b.p. 163°/1 mm.; *bis-2-benzoyloxy*-, m.p. 74°; *bis-2-acetoxy*-, m.p. 92°; 2:4'-*dihydroxy*-, m.p. 76°; 2:4'-*dimethoxy*-, b.p. 171°/1 mm.; 2:4'-*diethoxy*-, m.p. 106°; 2:4'-*diacetoxy*-, m.p. 56°; 2:4'-*dibenzoyloxy*-, m.p. 102°; 2:3'-*dihydroxy*-, m.p. 88.5°; 2:3'-*dimethoxy*-, m.p. 75°; 3:4'-*dihydroxy*-, m.p. 110°; 3:4'-*dimethoxy*-, b.p. 153°/1 mm. When heated  $o\text{-(OMe}\cdot\text{C}_6\text{H}_4\cdot\text{Se})_2\text{Pb}$  affords  $o\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{SeMe}$  and a substance, m.p. 186°. Dimethoxydiazonium chlorides condense with  $\text{PhSeNa}$ , and treatment of the products with  $\text{RMgI}$  yields: 2-*phenylselenoresorcinol Me<sub>2</sub> ether*, m.p. 78.5—79°, *Me<sub>1</sub> ether*, b.p. 147—148°/0.5 mm., *monoacetate*, m.p. 60°, *diacetate*, m.p. 63°; *phenylselenoquinol Me<sub>2</sub> ether*, m.p. 43°, *Me<sub>1</sub> ether*, b.p. 165°/1 mm., *dibenzoate*, m.p. 147°; *phenylselenopyrocatechol*, b.p. 176°/1 mm., *Me<sub>2</sub> ether*, m.p. 63°, *Me<sub>1</sub> ether*, b.p. 166—167°/1 mm. The method is also adapted to the prep. of salicylic acid derivatives: the following are described: 5-*phenylselenosalicylic acid* (IV), m.p. 167.5°; *Me 5-benzylideneamino-salicylate*, m.p. 61° (*Ac derivative*, m.p. 106°); *Me 5-aminoacetylsalicylate* (V), m.p. 102°; *Me 5-phenylselenoacetylsalicylate*, m.p. 70°. Diazotised (V) with  $\text{KSeCN}$  affords *Me 5-(selenocyano)acetylsalicylate*, m.p. 69°, which is hydrogenated to *Me o-acetylselenoquinolcarboxylate*, b.p. 137—138°/2.5 mm. This is oxidised to *Me bis-p-acetoxyphenyl diselenide bis-m-carboxylate*, m.p. 90°, hydrolysed to *bis-(m-carboxy-p-hydroxyphenyl) diselenide*, m.p. 231.5°. Treatment of the *Me ester* of (IV) and its isomerides with  $\text{Pb(OAc)}_2$ , followed by  $\text{MeI}$  and by hydrolysis, affords *o*-, m.p. 180—181° (*Me ester*, m.p. 65°),  $m$ -, m.p. 122° (*Me ester*, b.p. 105—106°/3.5 mm.), and  $p$ -, m.p. 174° (*Me ester*, m.p. 83°), *-methylselenobenzoic acid*. *o*-, m.p. 94°,  $m$ -, m.p. 39°, and  $p$ -, m.p. 98°, *-Methoxyphenyl-α-naphthyl selenide* are obtained by condensation of the appropriate anisidine diazonium salt with  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{SeNa}$ . With  $\text{MeMgI}$  these yield *o*-, m.p. 95°,  $m$ -, m.p. 71°, and  $p$ -, m.p. 98°, *-hydroxyphenyl α-naphthyl selenide*. 4:1- $\text{NH}_2\cdot\text{C}_{10}\text{H}_6\cdot\text{OH}$  and  $\text{PhCHO}$ , followed by  $\text{Ac}_2\text{O}$ , yield 4-*benzylideneamino-α-naphthyl acetate*, m.p. 90°; with  $\text{HCl}$  this affords 4-*amino-α-naphthyl acetate hydrochloride*, m.p. 216°. This is diazotised and coupled with  $\text{PhSeNa}$ : hydrolysis affords 4-*phenylseleno-α-naphthol*, m.p. 75° (*acetate*, m.p. 78.5°; *Et ether*, m.p. 107°). Methoxynaphthylidiazonium chlorides and  $\text{PhSeNa}$ , followed by  $\text{RMgI}$ , afford 2-*phenylseleno-α-naphthol*, m.p. 65° (*Me ether*, m.p. 63°), and 1-*phenylseleno-β-naphthol*, m.p. 79° (*Et ether*, m.p. 63°). *Ph 3-pyridyl selenide*, b.p. 128°/1.5 mm., is obtained similarly. CH. ABS. (r)

Optical activity of derivatives of quadrivalent tellurium containing two identical negative radicals. I. T. M. LOWRY and F. HUTHER. II. (Miss) M. G. TER HORST (Rec. trav. chim., 1936, 55, 688—696, 697—711).—I.  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{TePhBr}_2$  and Ag  $\alpha$ -bromocamphor- $\pi$ -sulphonate (2 mols.) in  $\text{COMe}_2$  give the disulphonate (I), which with  $\text{H}_2\text{O}$  affords phenyl- $p$ -tolyltelluronium hydroxy- $\alpha$ -bromocamphor- $\pi$ -sulphonate, m.p. between  $105^\circ$  and  $150^\circ$ , which exhibits downward mutarotation. In MeOH a similar salt is obtained, m.p. between  $150^\circ$  and  $180^\circ$ , exhibiting upward mutarotation. Crystallisation to const. m.p. ( $180^\circ$ ) gives the *dl*-compound, exhibiting no mutarotation. Each salt with NaOH gives phenyl- $p$ -tolyltelluronium dihydroxide, mutarotating rapidly in the same direction as the parent salt; both active forms and the *dl*-form melt at  $148^\circ$  and there are no depressions on admixture.  $\text{Te}^{\text{IV}}$  compounds with two identical negative groups thus have optical activity.

II. (I), the dibromide and di-iodide [prep. from (I) by KBr or KI], and diphenyltelluronium di- $\alpha$ -bromocamphor- $\pi$ -sulphonate and dibromide show very rapid mutarotation.  $\alpha$  observed are very small, but the changes are considered definite. Jaeger's theory that the tetrahedron of  $\text{Te}^{\text{IV}}$  is irregular is thus supported.

R. S. C.

Organo-metallic compounds. I. Aromatic tellurium compounds. L. REICHEL and E. KIRSCHBAUM (Annalen, 1936, 523, 211—223).—Various types of  $\text{Te}^{\text{IV}}$  compounds are prepared.

$[\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{TeMeEt}]^+$  and  $\text{C}_6\text{H}_5\text{Mo}\cdot\text{TePhO}$  give rise to optical activity, but only in combination with optically active anions etc. Dry  $\text{TeCl}_4$  (prep. in 60—75% yield described) and  $\text{PhOEt}$  or  $\text{PhOMe}$  in dry  $\text{CCl}_4$  give *p*-phenetyl- (cf. A., 1926, 83), m.p.  $184^\circ$ , and *p*-anisyl-tellurium trichloride, m.p.  $182^\circ$ , converted by  $\text{H}_2\text{O}$  into *p*-phenetyl- and *p*-anisyl-tellurium oxychloride, both decomp.  $400\text{—}500^\circ$ , which with  $\text{Ag}_2\text{O}$  regenerate the ethers, but with hot 70—80% NaOH give *p*-phenetyl- and *p*-anisyl-tellurous acid,  $\text{RTeO}_2\text{H}$ , both m.p. indef., and with  $\text{K}_2\text{S}_2\text{O}_5$  give *di*-*p*-phenetyl, m.p.  $109^\circ$ , and -anisyl ditelluride (I),  $\text{R}_2\text{Te}_2$ , m.p.  $60^\circ$ .  $\text{TeCl}_4$  and  $\text{PhOH}$  decompose at  $150\text{—}180^\circ$ , but at about  $90^\circ$  or in hot  $\text{CCl}_4$  give *p*-hydroxyphenyltellurium trichloride, m.p.  $233^\circ$  (cf. Rust. A., 1898, i, 137), converted by  $\text{H}_2\text{O}$  into the oxychloride, m.p. indef. (decomp.), by 2*N*-NaOH into *p*-hydroxyphenyltellurous acid (II), m.p. indef. (decomp.), and by  $\text{K}_2\text{S}_2\text{O}_5$  into *di*-*p*-hydroxyphenyl ditelluride (III), m.p.  $93^\circ$ . With  $\text{HNO}_3$  (1 mol.)  $\text{—H}_2\text{SO}_4$  (II) gives the 2- $\text{NO}_2$ -acid, m.p.  $221^\circ$  (decomp.), with 2 mols. the 2:6-dinitro-acid, reducible to the  $\text{NO}_2$ -, m.p.  $150^\circ$  (decomp.), and  $(\text{NO}_2)_2$ -derivative (IV), m.p.  $153^\circ$  (decomp.), respectively, of (III). (II) and  $\text{HNO}_3$  (3 mol.)  $\text{—H}_2\text{SO}_4$  give the mixed anhydride,  $(\text{NO}_2)_2\text{C}_6\text{H}_4(\text{OH})\cdot\text{TeO}\cdot\text{O}\cdot\text{NO}_2$ , giving (IV) with hot 20%  $\text{H}_2\text{SO}_4$ , but not reduced to a ditelluride.  $\text{NHPhAc}$  and  $\text{TeCl}_4$  alone at  $115^\circ$  or in hot  $\text{CCl}_4$  give a product, reduced to *di*-*p*-acetanilide ditelluride, decomp.  $172^\circ$ . The  $\text{NO}_2$ -compounds cannot be reduced to  $\text{NH}_2$ -derivatives and no products are obtained from  $\text{TeCl}_4$  and  $\text{NH}_2$ -compounds. (I) and hot MeI give *p*-anisylmethyltellurium di-iodide (V) and *p*-anisyl dimethyltellurium iodide [also obtained

from (V), MeI, and  $\text{K}_2\text{S}_2\text{O}_5$ ]. (V) and alkaline  $\text{K}_2\text{S}_2\text{O}_5$  give anisyl Me telluride, b.p.  $150\text{—}152^\circ/20\text{ mm.}$ , which with EtI gives *p*-anisylmethylthyltelluronium iodide, m.p.  $168^\circ$  [also obtained from (V), EtI, and  $\text{K}_2\text{S}_2\text{O}_5$ ]; the *d*-bromocamphor- $\pi$ -sulphonate, m.p.  $149^\circ$ , of the corresponding *l*-cation is obtained with  $[\text{M}]_D +198.58^\circ$  in  $\text{CHCl}_3$ , whence  $[\text{M}]_D$  for the cation is  $-71.42^\circ$ . The *d*-camphor- $\beta$ -sulphonate, m.p.  $93^\circ$ , of *d*-Ph *p*-tolyl telluroxide is obtained with  $[\text{M}]_D +450.5^\circ$  in  $\text{COMe}_2$ . Both salts give *dl*-compounds when the active acid is removed. R. S. C.

Diphenylene telluride. C. COURTOT and M. G. BASTANI (Compt. rend., 1936, 203, 197—199; cf. A., 1934, 1119).— $\text{TePh}_2\text{O}$  is not cyclised with  $\text{NaNH}_2$ , nor does diphenylene sulphone react with Te. The diazonium chloride of  $o\text{-C}_6\text{H}_4\text{Ph}\cdot\text{NH}_2$  with  $\text{HgCl}_2$  affords diphenyl *o*-mercuric chloride, m.p.  $165\text{—}167^\circ$ , which resists cyclisation.  $\text{Ph}_2$  with  $\text{TeCl}_4$  at  $140\text{—}165^\circ$  affords diphenylene telluride dichloride (I) (decomp. about  $200^\circ$ ) (a little dibromide, decomp.  $210\text{—}220^\circ$ , is formed with  $\text{TeBr}_4$ ), hydrolysed to diphenylenetellurine, decomp.  $230\text{—}240^\circ$ , which with hot H halides gives dihalogenated compounds. (I) with  $\text{KHSO}_3$  affords diphenylene telluride,

J. L. D.

Rotatory power of gelatin fractions.—See this vol., 1202.

Ultimate analysis of organic substances from combustion in a bomb calorimeter. P. J. MERKUS and A. H. WHITE (Proc. Amer. Gas Assoc., 1934, 991—1001).—Combustion is carried out in a bomb containing  $\text{O}_2$ . The analysis is based on pressure measurements.

CH. ABS. (e)

Micro-determination of carbon dioxide and hydrogen in elementary analysis.—See this vol., 1220.

Semi-micro-combustion method for determining nitrogen in organic compounds. C. F. H. ALLEN and D. M. YOUNG (Canad. J. Res., 1936, 14, B, 216—221).—A modified Dumas method requiring 20—30 mg. of org. compound is described. Pure  $\text{CO}_2$ , obtained by heating  $\text{NaHCO}_3$  and stored over Hg, is passed at a controlled speed through the combustion tube. The % of N is determined to within  $\pm 0.2$ .

J. G. A. G.

Iodometric micro-determination of nitrogen. S. MORGULIS and A. F. FRIEDMAN (Bull. Soc. Chim. biol., 1936, 18, 1074—1080).—The described method is suitable for the micro-determination of N in  $\text{NH}_4$  salts and  $\text{CO}(\text{NH}_2)_2$ , but not for Kjeldahl digests.

A. L.

Volumetric adsorption methods.—See this vol., 1225.

Analysis of organic substances by means of the Raman effect. W. HANLE and F. HEIDENREICH (Physikal. Z., 1936, 37, 594—595).—The conditions under which the Raman spectrum of a mixture of org. substances may be used to discover the constituents of the mixture are discussed. A mixture of  $\text{C}_6\text{H}_6$  and dioxan was particularly considered, the ratio of the intensities of two neighbouring

lines in the Raman spectrum, one due to  $C_6H_6$ , the other to dioxan, being determined for mixtures of different compositions. A. J. M.

**Basic titration of acetic acid.**—See this vol., 1203.

**Step-wise separation and useful effect. Construction of separation diagrams.** J. P. TREUB (Chem. Weekblad, 1936, 33, 496—500).—A mathematical discussion and practical illustration of the separation of solid and liquid fatty acids by step-wise freezing and pressing at progressively increased temp. The separation is illustrated by f.-p. curves. S. C.

**Relation between emulsion technique and analytical and organic chemistry.** A. STEIGMANN (Phot. Ind., 1936, 34, 963—966).—The possible use of the effects of a given substance on photographic emulsions, as an aid in analysis, is reviewed. Many substances, e.g., of the cystine group, show well-defined results, but the reactions are not generally sp. The prep. of a new desensitising compound, "cyclocystine," is described. J. L.

**Colour reaction for aromatic amines.** T. YAMANAKA (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 43).—Pure  $NH_2Ph$  gives a dark green colour and  $NH_2Ph$  containing  $>1\%$   $C_6H_4Me \cdot NH_2$  a dark or reddish-brown colour, when warmed with dil.  $H_2SO_4$  and a few drops of  $NH_4VO_3$  and  $KClO_3$  solutions. The presence of 0.01—1% of  $C_6H_4Me \cdot NH_2$  in  $NH_2Ph$  is detected by removing the  $NH_2Ph$  by Lewy's method, warming the  $HCl$  solution with a few drops of  $NH_4VO_3$  and *p*-tolylenediamine solutions and finally with a few drops of aq.  $KClO_3$ , when a bluish-violet or violet colour develops; in the absence of  $C_6H_4Me \cdot NH_2$  the colour is scarlet or purple-red. Methods are also given for the detection of  $PhNO_2$  in  $NH_2Ph$ . W. O. K.

**Volumetric determination of the xylidine isomerides with bromide-bromate solution.** B. P. FEDOROV and A. A. SPRISKOV (Z. anal. Chem., 1936, 105, 412—418).—Titration of commercial xylidine (I) with  $KBr-KBrO_3$  solution (II) results in the formation of  $Br_1$ -derivatives of the *m*- and  $Br_2$ -derivatives of the *o*- and *p*-isomerides. The (I) is dissolved in 95%  $EtOH$ , previously treated with  $HCl$  gas until 8 g. per 100 c.c. has been absorbed, (II) is added until a permanent brown colour persists, and, after addition of  $KI$ , the excess of (II) is determined by titration with  $Na_2S_2O_3$ . A. R. P.

**Determination of phenols.** R. W. STOUGHTON (J. Biol. Chem., 1936, 115, 292—298).—5 drops of  $H_2SO_4$  and 2 drops of  $HNO_3$  are added to 6 c.c. of an  $AcOH$  solution of the phenol; the mixture is warmed until the colour is fully developed (2—10 min.), diluted with 5—10 c.c. of  $H_2O$ , treated with 15 c.c. of conc. aq.  $NH_3$ , and made up to 50 c.c. The yellow colour is matched against that given by a standard (1:6000) solution of the same phenol. Phenols in biological material are first isolated by distillation of the acid ( $H_3PO_4$ ) solution in steam and extraction of the distillate thrice with  $Et_2O$ . Phenols containing also a CO do not respond to the test. The colour depends on formation of a NO-compound;  $HNO_2$

leads to a similar colour in a few sec., but side-reactions alter the shade. R. S. C.

**Specificity of the phenol reagent of Folin and Ciocalteu for determination of tryptophan.** E. SCHILD and C. ENDERS (Biochem. Z., 1936, 286, 220—224).—The reaction with this reagent is due to the reducing power of the tested substance and is not sp. A table gives a series of substances found in physiological fluids and natural products which give positive reactions. The reaction gives untrustworthy results with protein hydrolysates, wort, and beers. P. W. C.

**Determination of phenol and cresols in presence of each other.** V. MIKLASCHESKAYA (Chim. Tverd. Topl., 1934, 5, 553—558).—On heating to 80° with  $KMnO_4$  and dil.  $H_2SO_4$   $PhOH$  is oxidised to  $CO_2$  and  $H_2O$ , whilst cresol forms  $CO_2$ ,  $H_2O$ , and  $AcOH$ . The  $KMnO_4$  reduced and the  $AcOH$  formed are determined volumetrically. CH. ABS. (e)

***m*-Chlorobenzhydrazide as a reagent for the identification of aldehydes and ketones.** P. P. T. SAH and C. S. WU (Sci. Rept. Nat. Tsing Hua Univ., 1936, 3, 443—449).—*m*-Chlorobenzhydrazide, m.p. 157—158°, obtained from *m*- $C_6H_4Cl \cdot CO_2Et$  and  $N_2H_4 \cdot H_2O$ , may be used to prepare the *m*-chlorobenzoylhydrazones of the following:  $MeCHO$ , m.p. 154—155°,  $EtCHO$ , m.p. 124—125°,  $Pr^iCHO$ , m.p. 156—157°,  $Pr^sCHO$ , m.p. 160—161°, *n*-valeraldehyde, m.p. 152—153°,  $PhCHO$ , m.p. 118°, *m*- $NO_2 \cdot C_6H_4 \cdot CHO$ , m.p. 209—210°, *o*-, m.p. 207—208°, and *p*- $OH \cdot C_6H_4 \cdot CHO$ , m.p. 247—248°,  $CHPh \cdot CH \cdot CHO$ , m.p. 208—209°, furfuraldehyde, m.p. 184—185°,  $COMe_2$ , m.p. 97°, cyclopentanone, m.p. 172—173°, cyclohexanone, m.p. 138—139°,  $COPhMe$ , m.p. 150—151°, *p*- $C_6H_4Cl \cdot COMe$ , m.p. 159—160°, *p*- $C_6H_4Br \cdot COMe$ , m.p. 206—207°, *p*- $C_6H_4Me \cdot COMe$ , m.p. 211—213°,  $COPh_2$ , m.p. 146—148°, styryl Me ketone, m.p. 171—172°, pinacolin, m.p. 144—145°, and lævulic acid, m.p. 155—156°. F. R. S.

**Hydrazines.** V. *m*-Tolylhydrazine as a reagent for the identification of aldehydes and ketones. VI. Identification of sugars by means of the three isomeric tolylhydrazines. P. P. T. SAH and C. Z. TSEU (Sci. Rept. Nat. Tsing Hua Univ., 1936, 3, 403—407, 409—416).—V. The *m*-tolylhydrazones of the following have been prepared:  $PhCHO$ , m.p. 97—98°, *o*-, m.p. 140—141°, and *p*- $OH \cdot C_6H_4 \cdot CHO$ , m.p. 151—152°, *m*-, m.p. 123—124°, and *p*- $NO_2 \cdot C_6H_4 \cdot CHO$ , m.p. 106—107°, styryl Me ketone, m.p. 97—98°. *Et* lævulate, m.p. 102°, lævulic acid, m.p. 133°,  $CHPh \cdot CH \cdot CHO$ , m.p. 131—132°,  $COPh_2$ , m.p. 49—50°, and *o*- $C_6H_4Br \cdot COMe$ , m.p. 90—91°.

VI. The following hydrazones and osazones are insol.: *d*-galactose-*o*-, m.p. 176—177°, *p*-, m.p. 156°, and *m*-, m.p. 153—154°, *d*-mannose-*p*-, m.p. 190°, and *l*-arabinose-*p*-, m.p. 159—160°, and *m*-tolylhydrazones, m.p. 157°; *d*-glucose-*p*-, m.p. 195—196°, *m*-, m.p. 177—178°, and *o*-, m.p. 204—205°, *d*-mannose-*p*-, m.p. 196°, *m*-, m.p. 177—178°, and *o*-, m.p. 204—205°, *d*-galactose-*p*-, m.p. 193°, and *o*-, m.p. 165°, *lactose*-*p*-, m.p. 208—209°, *o*-, m.p. 207—208°, and *m*-, m.p. 189—190°, *maltose*-*p*-, m.p. 159°, *m*-, m.p. 156°, and *o*-, m.p. 169°, *l*-arabinose-*p*-,

m.p. 176—177°, and -o-, m.p. 133°, d-xylose-p-, m.p. 175—176°, -m-, m.p. 157—158°, and -o-tolyl-*osazone*, m.p. 98—99°. F. R. S.

**Reagent for oxidising substances.** P. PRATESI and R. CELEGHINI (*Gazzetta*, 1936, **66**, 365—370).—3 : 6-Dibromo-2 : 5-bis-(2' : 4'-dimethyl-1'-pyrryl)-quinol (this vol., 999), of which the prep. is described in detail, is a sensitive reagent for peroxides; thus with  $\text{H}_2\text{O}_2$ ,  $\text{BzO}_2\text{H}$ ,  $o\text{-CO}_2\text{H}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ ,  $\text{MeEtO}_2$ ,  $\text{Bz}_2\text{O}_2$ ,  $(\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CO})_2\text{O}_2$ ,  $(o\text{-CO}_2\text{H}\cdot\text{C}_6\text{H}_4\cdot\text{CO})_2\text{O}_2$ , and  $(o\text{-CO}_2\text{Et}\cdot\text{C}_6\text{H}_4\cdot\text{CO})_2\text{O}_2$ , in  $\text{C}_5\text{H}_5\text{N}$ , the intense blue colour of the benzoquinone is formed. The reagent will detect 0.05 mg. of  $\text{BzO}_2\text{H}$ , and shows its formation during the autoxidation of  $\text{PhCHO}$ , and that of peroxides in the autoxidation of terpenes and styrenes. The quinol also reacts with benzo-, tolu-, thymo-, and 2 : 5-dibromobenzo-quinone, and, in  $\text{EtOH}$  or dioxan, detects  $\text{Fe}^{+++}$  ( $< 0.002$  mg., and even in the presence of many other substances),  $\text{Fe}(\text{CN})_6^{+++}$ ,  $\text{Cl}'$ , and  $\text{Br}'$  in  $\text{H}_2\text{O}$ . In  $\text{EtOH}$ ,  $\text{EtOAc}$ , and dioxan the reagent is less sensitive to org. peroxides than in  $\text{C}_5\text{H}_5\text{N}$ . E. W. W.

**Structure of simple nucleic acids. IV. Determination of furfuraldehyde in pyrimidyl acids.** H. STREUDEL (*Z. physiol. Chem.*, 1936, **242**, 100).—The two cytosylic acids and uracilic acid give no furfuraldehyde when treated by Hoffman's method (cf. A., 1927, 687). W. McC.

**Reaction of quinine with various phenols.** R. LABES and K. WEDELL (*Arch. exp. Path. Pharm.*, 1936, **182**, 249—261).—The pptn. of quinine (I) by  $\text{PhOH}$ ,  $p\text{-C}_6\text{H}_4\text{Cl}\cdot\text{OH}$ , trichlorophenol, and picric acid depends on the hydrophobic nature of groups substituted in  $\text{PhOH}$  and only to a limited extent on  $[\text{H}']$ . The ease of pptn. of (I) from very dil. solution is discussed with reference to its action on biological processes in which phenolic substances are concerned. F. O. H.

**Solubility products of strychnine with various phenols.** (Chemical constitution and biochemical action.) R. LABES and F. LU (*Biochem. Z.*, 1936, **286**, 232—247).—Strychnine gives difficultly sol. reaction products with a large no. of investigated phenolic derivatives, in the formation of which the mass law is obeyed and for which solubility products can be determined. The latter are the smaller, i.e., extend to greater dilutions, the greater is the no. of hydrophobic groups substituted in the phenol. The effect is maintained down to concns. of alkaloid which are pharmacologically active. Detection of alkaloids by means of picric acid is a special case of this reaction. P. W. C.

**Titration of alkaloids in anhydrous media.** G. N. THOMAS (*J. Pharm. Chim.*, 1936, [viii], **24**, 162—173).—A criticism of various methods. The author concludes that his method (B., 1935, 1117) offers advantages over the others (error is  $\pm 0.1\%$ ). J. N. A.

**Determination of methionine in proteins.** H. D. BAERNSTEIN (*J. Biol. Chem.*, 1936, **115**, 25—32).—After hydrolysis and demethylation with  $\text{HI}$ , homocysteine is oxidised with  $\text{Na}_2\text{S}_4\text{O}_6$  (reaction is sp. for oxidation of  $\cdot\text{SH}$ ) and the  $\text{Na}_2\text{S}_2\text{O}_3$  formed titrated with  $\text{KIO}_3\text{--HIO}_3$  (I). Cysteine must be determined also, preferably with (I). Methionine may be also determined by absorption of  $\text{MeI}$  during the process and gives satisfactory results if  $\text{Et}_2\text{O}$ ,  $\text{EtOH}$ , and fat are absent. Glucose yields no volatile I' under the prescribed conditions. H. G. R.

**Sulphur distribution in proteins. II. Combined methods for determination of cystine, methionine, and sulphates in hydriodic acid digests.** H. D. BAERNSTEIN (*J. Biol. Chem.*, 1936, **115**, 33—36).—The distribution of S in 11 proteins (average recovery 96.9%) by the new system of analysis (cf. preceding abstract) is described. H. G. R.

## Biochemistry.

**Blood-gases in pneumectomised animals.** J. ENSELME, M. DARGENT, and D. CHEVASSU (*Bull. Soc. Chim. biol.*, 1936, **18**, 1352—1355).—Pneumectomy in the rabbit is followed by an increased  $\text{O}_2$ -capacity and haemoglobin content of the blood. H. D.

**Insulin-decomposing power of erythrocytes.** F. ROSENTHAL, I. FRIEDHEIM, and R. NAGEL (*Klin. Woch.*, 1935, **14**, 603—606; *Chem. Zentr.*, 1935, ii, 3536).—The reaction between insulin and haemolysed human erythrocytes is examined *in vitro*. A. G. P.

**Extraction of lipins from red blood cells.** E. M. BOYD (*J. Biol. Chem.*, 1936, **115**, 37—45).—After haemolysis with an equal vol. of  $\text{H}_2\text{O}$ , the cells are extracted with  $\text{EtOH}\text{--Et}_2\text{O}$  (25—30 vols. per 1 vol. of cells) without heating. The val. obtained from oxalated is  $>$  that from defibrinated blood. H. G. R.

**Cholesterol content of blood corpuscles.** G. LAROCHE and A. GRIGAUT (*Compt. rend. Soc. Biol.*, 1936, **122**, 1253—1255).—The cholesterol content of red cells is approx. 1.5 g. per litre, being  $<$  that of the plasma. H. G. R.

**Preservation of erythrocytes with naphthalene-1 : 6-disulphonate.** H. GOLDIE (*Compt. rend. Soc. Biol.*, 1936, **122**, 1218—1221).—Erythrocytes of sheep can be preserved for serological reactions for  $< 4$  months in a 0.5—0.75% solution of the Na salt. H. G. R.

**Daily variation in eosinophile numbers in blood; influence of adrenaline.** I. DJAVID (*Klin. Woch.*, 1935, **14**, 930—931; *Chem. Zentr.*, 1935, ii, 3400).—Regular variations are recorded. These are unaffected by adrenaline. A. G. P.

**Absorption spectra of oxyhaemoglobin of some Vertebrata.** T. TUTSCHOLSKI and A. WOŁOSZCZUK (*Acta phys. Polon.*, 1934, **3**, 271—278).—The absorption spectra of oxyhaemoglobin from man, guinea-pig, and frog show identical structure. The absorption intensity varies with the source. CH. ABS. (p)

Reaction of cyanide with the hæmocyenin of *Limulus polyphemus*. O. H. PEARSON (J. Biol. Chem., 1936, 115, 171—177).—CN' reacts with oxyhæmocyenin, removing O and forming a rather stable cyanohæmocyenin, in which 4 CN are associated with 2 Cu. The reaction is reversed by dialysis. The relative affinities of salt-free hæmocyenin for O and CN' are approx. 5:1. J. N. A.

Determination of the isoionic point of hæmoglo-bin and total serum-proteins. M. LÉVY, S. MIGNON, and A. NETTER (Bull. Soc. Chim. biol., 1936, 18, 1311—1324).—The dialysis method for the determination of the isoionic points of proteins (Sandor, this vol., 1008) is applied to (human) total serum-proteins and hæmoglo-bin, giving mean normal vals. of  $p_H$  5.35 and 7.09, respectively. Variations are observed in pathological conditions. H. D.

Serum-proteins during anaphylactic state [in man]. AUBRY, THIODET, and RIBERE (Bull. Soc. Chim. biol., 1936, 18, 1356—1360).—An increase in the albumin/globulin ratio occurs. H. D.

Flocculation of globulin in diluted serum. M. DOLADILHE and C. MOREL (Compt. rend. Soc. Biol., 1936, 122, 1310—1311).—[H'] is the chief factor causing the flocculation of globulin on dilution and may be stabilised by the addition of NaHCO<sub>3</sub>. H. G. R.

Lipin-protein complexes and ageing of blood-serum. B. DELAGE (Bull. Soc. Chim. biol., 1936, 18, 1304—1310).—Aseptic horse serum, kept at 0° for periods up to one year, shows a progressive decrease in the lipins extractable by cold EtOH-Et<sub>2</sub>O. The quantity extractable increases to a max. with increasing [EtOH] in the mixture. H. D.

Blood-fibrin. Protein structure. M. BERGMANN and C. NIEMANN (J. Biol. Chem., 1936, 115, 77—85).—Fibrin (ox) on hydrolysis yields arginine (I) 7.5%, histidine 2.5%, lysine 10.1%, glutamic acid 14.0%, aspartic acid (II) 5.3%, and proline (III) 4.9%, (I), (II), and (III) being produced in equiv. amounts. The distribution of the NH<sub>2</sub>-acids follows one of two arithmetical series. H. G. R.

Mechanism of spontaneous hydrolysis of the organic phosphorus of blood *in vitro*. G. DE TONI and G. GRAF (Biochim. Terap. sperim., 1935, 22, 395—410; Chem. Zentr., 1935, ii, 3670).—The increase in inorg. P during autolysis of blood *in vitro* is due entirely to phosphatase, and does not occur when the action of the enzyme is prevented by addition of CCl<sub>3</sub>·CO<sub>2</sub>H. A. G. P.

Blood plasma-cholesterol and -phospholipin-phosphorus in rats following partial hepatectomy or ligation of the bile duct. A. CHANUTIN and S. LUDEWIG (J. Biol. Chem., 1936, 115, 1—7).—After partial hepatectomy a decrease in cholesterol (I) esters occurred on the 1st day, returning to normal on the 2nd day, when an increase in free (I) was noted. Free (I) is increased and (I) esters are normal in rats with ligated bile duct; in all cases phospholipin-P  $\propto$  the concn. of free (I). H. G. R.

Blood-phospholipin as a transport mechanism. R. G. SINCLAIR (J. Biol. Chem., 1936, 115,

211—220).—The elaidic acid (I) content of plasma-phospholipins (II) rises rapidly after ingestion of (I) (as mixed glyceride), indicating that (II) enter into the transport of fatty acids. Only after 2 days' continuous feeding of (I) does it appear in the erythrocyte-(II). H. D.

Selenium as catalyst in determination of non-protein-nitrogen in blood. F. REIS and H. H. POWERS (J. Lab. Clin. Med., 1935, 20, 1204—1206).—Technique for examining Folin-Wu blood filtrates is described. CH. ABS. (p)

Histamine or a similar substance in rabbits' blood. B. TARRAS-WAHLBERG (Klin. Woch., 1935, 14, 1285—1287; Chem. Zentr., 1935, ii, 3402).—The blood contains  $0.5 \times 10^{-6}$  g. per c.c. of histamine (I) or a substance exhibiting the biological reactions of (I). A. G. P.

Aminoacidæmia and the action of hypotensive substances. G. DE NITO (Boll. Soc. ital. Biol. sperim., 1936, 11, 160—161).—Hypotensive substances decrease the blood-NH<sub>2</sub>-acid level by increasing the deaminating activity of the blood as shown by deamination of glycine. F. O. H.

Influence of various substances on the change of state of uric acid in the serum. I, II. Y. NUKITA (Folia Pharmacol. Japon., 1935, 20, 30—37).—I. Protein in the serum stabilises uric acid (I). In presence of Na and Mg salts (I) separates less readily from serum. K<sub>2</sub>SO<sub>4</sub> and KCNS have a similar influence, but KCl, KNO<sub>3</sub>, CaCl<sub>2</sub>, and CaSO<sub>4</sub> have the reverse effect.

II. The action of serum-protein is unaltered by purification by electrodialysis. CH. ABS. (p)

Content of nitrogenous degradation products in the serum of ungulates. A. URBAIN and R. CAHEN (Compt. rend., 1936, 203, 342—345).—The urea content of the serum of non-ruminants is approx. const. for the same species and is <0.5 g. per litre. Great variations from animal to animal are found among ruminants; the content is about 0.4 g. for oxen and reaches 0.7 g. for goats and camels. Uric acid is present in very small amount in comparison with that in human serum. The total non-protein-N is very low. H. W.

Reduced glutathione in the blood of ungulates. A. URBAIN, R. CAHEN, and M. A. PASQUIER (Compt. rend. Soc. Biol., 1936, 122, 1210—1211).—In the ruminants individual variations in the same species were observed. The val. for domestic *Caprinæ* is similar to that of man, but it is greater in the *Camelidæ* and *Cervidæ*. H. G. R.

Determination of urea in blood. C. A. SAGASTUME and R. A. CRESPI GHERZI (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 47—49).—The authors' reagent (see this vol., 1288) with Na<sub>2</sub>SO<sub>4</sub> in place of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is recommended for deproteinisation of blood prior to determination of urea. F. R. G.

Composition of elk's blood. J. BRUGEMANN (Z. physiol. Chem., 1936, 242, 169—170).—The following vals. (mg. per 100 c.c.) were obtained with the blood of a female (1 year): total N 3136—3864, residual N 19—50, sugar (I) 34—58, lactose (II) 19—38,

Na 170—326, Cl 337—390. In the plasma the (I) and (II) vals. were 62—87 and 20—36, respectively, and the alkali reserve was 44—66 vols. per 100 vols. In the serum the Ca, P, Na, and Cl vals. were 8.2—9.8, 6.5—11.2, 367—433, and 305—369, respectively.

W. McC.

Has orally-administered saccharin an influence on blood-sugar? F. FISCHLER and A. SCHROTER (Deut. med. Woch., 1935, 61, 1354—1358; Chem. Zentr., 1935, ii, 3536).—No effect was observed.

A. G. P.

Effect of hypertonic, intra-arterial injections on blood-sugar. A. BAUDOUIN, J. LEWIN, and E. AZÉRAD (Compt. rend. Soc. Biol., 1936, 122, 1193—1195).—Hypoglycæmia was induced.

H. G. R.

Glycæmia and its regulation in carbohydrate metabolism. A. TURLETTI (Rass. clin. Terap. Sci. affini, 1935, 34, 152—171; Chem. Zentr., 1935, ii, 3405).—The opposing influences of insulin and adrenaline are utilised.

A. G. P.

[Hypo]glycæmia and increased temperature produced by external factors. M. SENDRAIL and L. TAMELET (Compt. rend. Soc. Biol., 1936, 122, 1262—1264).—With dogs kept at a temp. between 45° and 50°, the blood-sugar falls during the first 10 min. and then increases; the temp. of the animal reached 42.5° in 45 min.

H. G. R.

Colorimetric determination of glucose in blood.—See this vol., 1234.

Influence of lactic acid on the determination of blood-ketones. G. W. SCHWARZBERG (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 105—112).—The presence of normal amounts of lactic acid in blood does not affect the determination of ketones.

F. R. G.

Exchange of sodium, potassium, and calcium between erythrocytes and plasma and content of these elements in plasma and serum. G. M. STREFF (Z. physiol. Chem., 1936, 242, 1—14; cf. Waelsch *et al.*, A., 1935, 1142).—In human and sheep's blood no appreciable amount of Na<sup>+</sup>, K<sup>+</sup>, and Ca<sup>++</sup> passes from erythrocytes to plasma or *vice versa* within 2 hr. after drawing.

W. McC.

Blood-sulphur. H. R. DALÓ (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 77—85).—The SO<sub>4</sub><sup>++</sup>-S and total S contents of the deproteinised blood of normal persons are 0.002—0.003 and 0.0045—0.0065%, respectively. Diabetes or tuberculosis does not affect, but uræmia increases, these vals.

F. R. G.

Spectrographic determination of lead in blood. K. CRUSE and H. SCHUBERT (Z. anal. Chem., 1936, 105, 241—256).—100 c.c. (0.01—0.1 mg. Pb) of blood are ashed at 500°, H<sub>2</sub>SO<sub>4</sub> being added. Pb is deposited electrolytically at 70°, with low c.d. on a pure Sn cathode (0.1 to 0.5 g., according to the amount of Pb), from a solution of the ash in aq. NH<sub>4</sub> tartrate of  $p_H$  6.2—6.4. The cathode is melted in a H<sub>2</sub> atm., and Pb is determined in its spark spectrum by the logarithmic sector method. Sources of subjective error in this method are discussed.

J. S. A.

Vasoconstrictive substance in blood, with special reference to high blood pressure. L. HANTSCHMANN (Z. ges. exp. Med., 1935, 96, 442—

467; Chem. Zentr., 1935, ii, 3401).—The constrictive action of blood and of various biological preps. is examined in relation to blood pressure and other disturbances.

A. G. P.

Interferometry of the refraction of blood-serum as a function of the concentration. R. JONNARD (Compt. rend., 1936, 203, 124—126; cf. this vol., 1038).—For 7 normal human sera,  $n$  varies from 1.349025 to 1.351320, but the rate of decrease of  $n$  with dilution (100—20%) with H<sub>2</sub>O varies from case to case. As the concn. approaches 20%, rabbit or horse serum shows a break in the curve, below which the relationship is not linear, probably corresponding with the flocculation of globulins.

J. L. D.

Interferometry of the refraction of serum in presence of foreign substances. R. JONNARD (Compt. rend. Soc. Biol., 1936, 122, 1305—1307).—On adding sugar to serum the observed increase in  $n$  is always > the calc. val.

H. G. R.

Interferometry of the refraction of serum in presence of electrolytes. R. JONNARD and F. ZUCKERKANDL (Compt. rend. Soc. Biol., 1936, 122, 1315—1316).— $n$  is increased by KCl and decreased by NaCl; in pathological cases the effect of KCl is more considerable.

H. G. R.

Modification in bactericidal power of blood by sodium citrate. P. CARNOT and H. LAVERGNE (Compt. rend. Soc. Biol., 1936, 122, 1249—1252).—The bactericidal power is decreased by 1—2% of Na citrate.

H. G. R.

Double mechanism of adenosine triphosphate stabilisation in cells. I. Reticulocytes. V. ENGELHARDT and M. LIUBIMOVA. II. Nucleated avian erythrocytes. V. ENGELHARDT and A. BAJEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 329—330, 331—333).—I. The maintenance of supplies of adenosine triphosphate (I) in the cells is effected by glycolysis and by respiration, both processes operating simultaneously. Inhibition of either process causes only a partial breakdown, but inhibition of both processes leads to complete disappearance of (I).

II. Inhibition of glycolysis results in increased NH<sub>3</sub> production, 50—80% of which is derived from (I). With deficient respiration the NH<sub>3</sub> produced is 10—20% > could be accounted for by decomp. of (I).

A. G. P.

Sensitising action of the leaf pigments, chlorophyll, carotene, and xanthophyll. F. M. KUEN and K. PURINGER (Biochem. Z., 1936, 286, 196—203).—Ethylchlorophyllide and EtOH extracts of green plants (*e.g.*, spinach) act photodynamically on red blood cells in the spectral range 296—579 m $\mu$ . EtOH extracts of *Selaginella* did not, but COMe<sub>2</sub> extracts and the pure chlorophyll (I) prep. therefrom did, show similarly strong sensitising action. The carotene (II) of *Selaginella* leaves acts similarly in the range 280—435 m $\mu$ , the action being < that of (I) in the longer  $\lambda$ . Xanthophyll and carrot-(II) act similarly to leaf-(II).

P. W. C.

**Pancreatic hæmolysin.** R. D. DE LA RIVIÈRE, N. KOSOVITCH, and S. ISHII (Compt. rend. Soc. Biol., 1936, 122, 1170—1173).—The hæmolysin is insol. in EtOH but sol. in Et<sub>2</sub>O and COMe<sub>2</sub>; it is not affected by boiling and is adsorbed on kaolin.

H. G. R.

**Chemistry of blood coagulation. I. Determination of inhibition of blood clotting. Methods and units. II. Inhibition of blood clotting by substances of high mol. wt.** E. CHARGAFF, F. W. BANCROFT, and M. STANLEY-BROWN (J. Biol. Chem., 1936, 115, 149—154, 155—161).—I. In determining the inhibitory activity of substances towards clotting of chicken plasma, the following conditions must be observed: (a) the reaction vol. is kept const., (b) the plasma is disturbed as little as possible, (c) the time taken for one determination is 6—10 min. The "inhibitor-unit" is the smallest amount of inhibitor which raises the clotting time of 0.1 c.c. of plasma to 4 times its normal val. at 30° under described conditions.

II. Na cellulose monosulphate is inactive, whilst cellulose disulphate and K polyvinyl sulphate are active (250 units per mg.). The Na salt of the naturally occurring galactansulphuric acid has an activity of 30 units per mg. Agar agar and the sp. polysaccharide from type III pneumococci are inactive. A substance, to act as inhibitor, must be H<sub>2</sub>O-sol., of high mol. wt., and contain combined H<sub>2</sub>SO<sub>4</sub> or possibly other acid groups of similar strength.

**Protective action of "germanin" (Bayer 205) on coagulation of blood-proteins.** V. KOCIAN (Arch. exp. Path. Pharm., 1936, 182, 313—316).—Pptn. of blood-proteins by tannic acid, CuSO<sub>4</sub>, or OsO<sub>4</sub> or coagulation at 60° is retarded by germanin; coagulation by AcOH, however, is enhanced. Coagulation occurs less readily with blood from young than from old persons; sex has no influence.

F. O. H.

**Stabilisation of fibrinogen in blood-plasma.** A. FISCHER (Enzymologia, 1936, 1, 81—84).—Clotting of purified fibrinogen by lipins is not inhibited by heparin. Addition of serum restores the inhibition.

E. D. Y.

**Group-specific A-substance in human urine and animal tissue.** K. FREUDENBERG, O. WESTPHAL, and P. GROENEWOUD (Naturwiss., 1936, 24, 522).—From human urine derived from blood group A, a product has been isolated, five times as active as that previously obtained, slightly dextrorotatory, containing galactose and Ac groups but not acetylglucosamine or uronic acids. In the urine of individuals of the O-group a similar substance, serologically inactive, poorer in C and richer in N than the A-substances and laevorotatory, is found. Purified A-factor from cattle or pig tissue may be detected serologically in amounts of  $5 \times 10^{-10}$  g. Its composition differs from that of the product obtained by Landsteiner (J. Exp. Med., 1936, 63, 185) from horse saliva. Hexose and Ac groups are present but not amino-hexose or uronic acids. Its properties are similar to those of the substances from human urine.

W. O. K.

**Immunochemistry of pyridine and its derivatives.** E. BERGER and H. ERLÉNMEYER (Klin. Woch., 1935, 14, 536—537; Chem. Zentr., 1935, ii, 3402).—Substitution by aliphatic side-chains does not change the serological action of C<sub>5</sub>H<sub>5</sub>N (I). Quinoline and nicotine behave similarly to (I). Hydrogenation, e.g., to piperidine, completely alters the reaction with antiserum.

A. G. P.

**Anti-complementary action of the urine of pregnant and of normal women.** L. GRIMARD (Compt. rend. Soc. Biol., 1936, 122, 1288—1290).—Normal urines of any origin have an anti-complementary action of variable intensity, generally < that of the serum.

H. G. R.

**Chemistry of anaphylactic shock.** A. SPITZ and A. HOCHWALD (Arch. exp. Path. Pharm., 1936, 182, 384—389).—Anaphylactic shock in dogs due to injection of horse serum is partly or completely inhibited by ascorbic acid (I). The sensitisation and shock are accompanied by increased residual C (II), sugar, and lactic acid levels of the blood [of these only (II) is affected by injection of (I)] and a decreased content of hydrolysable substances. The increase in (II) is a common but not essential symptom of shock.

F. O. H.

**Neutralising action of carbon disulphide on tetanus toxin *in vitro*.** L. VELLUZ (Compt. rend., 1936, 203, 471—472).—Freshly distilled CS<sub>2</sub> inactivates the toxin and the mixture may be injected without subsequent infection. The immunogenic ability of the mixture is retained. The reaction is unaffected by  $p_{H}$  (6—8) or by reduced pressure. CS<sub>2</sub> has no action on diphtheria toxin.

A. G. P.

**Chemical composition of teeth. IV. Calcium, magnesium, and phosphorus contents of the teeth of different animals. Mechanism of calcification.** M. M. MURRAY (Biochem. J., 1936, 30, 1567—1571; cf. this vol., 878).—The Mg and P contents of the ash of rodents' (rabbit, hare, guinea-pig, rat) teeth are > and the Ca content < those of human and dogs' teeth. In rodents the molars and incisors have different compositions. The Ca : P ratios vary from 1.75 (rats' incisors) to 2.09 (human dentine) the variations being due chiefly to alterations in Ca content coincident with changes in Mg content. When Mg is calc. as Ca the Ca : P ratios differ less. The wide variations in the mineral composition of teeth and of different tissues in the same tooth indicate that calcification is an active and sp. cell process and not merely a pptn. from saturated or supersaturated solutions of a salt of const. composition dependent on the ionic composition of the blood-plasma.

W. McC.

**Separation of enamel, dentine, and cementum.** P. J. BREKHUS and W. D. ARMSTRONG (J. Dental Res., 1935, 15, 23—29).—The fat-free material is dried, crushed, and separated by flotation in CHBr<sub>3</sub>-EtOH (5 : 1 vols.) having  $d_{20}^{25}$  2.53. Enamel sinks and the crude dentine (floating) is further separated from cementum by use of a flotation mixture having  $d_{20}^{25}$  2.04 (cementum floats). Enamel and dentine, thus prepared, contained Ca 34.3, 27.2, and P 17.5, 12.95%, respectively.

CH. ABS. (p)

**Mineral composition of bone.** M. COPPO (Arch. int. Pharm. Ther., 1935, 50, 328—331; Chem. Zentr., 1935, ii, 3534).—The composition of rabbit bones is comparable with that of human bones except that the Na and K contents are higher. The mineral composition of different bones from the same individual is more uniform than that of the same bone from different individuals. Vals. for compact are practically the same as those for spongy bones. During demineralisation, the Ca content falls and that of Mg increases irrespective of the cause of demineralisation. The % of  $H_2O$ , Na, K, and P is unchanged.

A. G. P.

**Relation between the magnesium of muscle and chronaxie.** R. WOLFF, M. RANGIER, and A. BOURQUARD (Compt. rend., 1936, 203, 414—416).—The amount of Mg in relation to dry wt. in the gastrocnemius, tibialis anterior, and semimembranosus muscles of the frog is nearly const. for each muscle, and an increase in Mg corresponds with a decrease in chronaxie. There is a close relation between intensity of glycolysis and functional activity of the muscle. Similar results are found for the muscles of *Astacus fluviatilis*. In spite of their higher chronaxie these contain more Mg than those of the frog.

J. N. A.

**Iron and copper in the liver and spleen of children of various ages.** E. LESNÉ, P. ZIZINE, and S. B. BRISKAS (Compt. rend. Soc. Biol., 1936, 122, 1271—1274).—In the foetal stage the liver and spleen contain a reserve of Cu and Fe and as growth proceeds the Cu val. decreases.

H. G. R.

**Composition of an intestinal concretion (enterolith) of a horse.** R. A. ROBINSON (New Zealand J. Sci. Tech., 1936, 18, 65—66).—The enterolith contained 53% of mineral matter consisting largely of struvite (probably), with smaller amounts of bobierrite and vivianite. No acid radical other than  $PO_4'''$  was present.

A. G. P.

**Composition of vesical calculi.** L. T. KYA (Chinese Med. J., 1936, 50, 797—806).—Of 42 calculi, 16 were composed principally of uric acid, 3 of  $PO_4'''$ , 4 of  $C_2O_4''$ , and 1 of cystine, whilst 18 were mixed stones.

W. O. K.

**Physiology of fur-bearing animals. I, II.** R. NESENI (Deut. tierarztl. Woch., 1934, 42, 643—644; 1935, 43, 241—243; Chem. Zentr., 1935, ii, 3398—3399).—Data are given concerning the digestive enzymes, contents of stomach and intestines, gall, liver, and fat of the silver and blue fox, nutria, etc.

A. G. P.

**Isoelectric point of animal tissues. III. Striped muscle. IV. Mouse erythrocytes.** G. YASUZUMI (Folia Anat. Japon., 1935, 13, 55—61, 332—342).—Data are recorded and the influence of different fixatives is examined.

Ch. Abs. (p)

**Isolation of acetic acid from mammalian liver.** R. P. COOK and K. HARRISON (Biochem. J., 1936, 30, 1640—1643).—AcOH was isolated as the 2:4-dinitrophenylhydrazide from fresh ox liver, together with the *osazone*, m.p. 175° (decomp.), of a substance of empirical formula  $C_8H_{12}O_6$ . The compound represents the major, if not the entire, part of the

$HSO_3$ -binding compounds of liver extract. Glucosazone was not detected.

P. W. C.

**Reducing substance in brain. I. Chemical tests. A. BONSIGNORE. II. Biological assay.** A. BONSIGNORE and C. ARDY (Boll. Soc. ital. Biol. sperim., 1936, 11, 92—94, 94—96).—The properties of ascorbic acid (I) added to brain-tissue indicate that the reducing substance titrated by 2:6-dichlorophenol-indophenol is (I); this is confirmed by feeding normal brain-tissue to scorbutic guinea-pigs.

F. O. H.

**Glycogen content of ascarids. I. A. SMORODINCEV and K. BEBESCHIN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 189—191).**—The glycogen (I) and lipin contents of female ascarids were > those of males. Differences in ash, total dry matter, and protein were smaller. All vals. tended to be smaller in *Taenia rhynchus saginatus* and still smaller in *Taenia solium* and *Diphyllobothrium latum*. On a dry-matter basis the (I) of *T. saginatus* was > that of ascarids. The protein of the latter was the more active.

A. G. P.

**Chitobiose octa-acetate from beetles.** L. ZECHMEISTER and I. PINCZÉSI (Z. physiol. Chem., 1936, 242, 97—99).—Chitin (I) from the wing-covers of the cockchafer (*Melolontha vulgaris*) yields the octa-acetate (II) with  $Ac_2O$ . (I) from the wings, thorax, and head of cantharides (*Lytta vesicatoria*) yields less pure (II) which is purified by treatment with NaOMe. Direct acetylation of cantharides yields impure (II).

W. McC.

**Liberation from the spinal cord of a substance similar to acetylcholine [during electrical stimulation].** B. MINZ (Compt. rend. Soc. Biol., 1936, 122, 1214—1216).

H. G. R.

**Physical chemistry of lipins. V. Behaviour of kephalin from human brain towards acids and bases.** M. SPIEGEL-ADOLF (Biochem. J., 1936, 30, 1536—1541).—1 g. of purified kephalin (I) in presence of excess of HCl neutralises 0.0086—0.0088 ml. of *N*-HCl. A (I)-HCl compound is pptd. when the [HCl] is further increased. The  $\eta$  of (I) solutions first decreases when HCl is added, but later increases before flocculation occurs. (I) can be pptd. by centrifuging only when the stage of increasing  $\eta$  has been reached. (I) also neutralises NaOH, the binding capacity increasing with [NaOH]. In fresh solutions of (I) with increasing [NaOH]  $\eta$  passes through a max. After 24 hr.  $\eta$  decreases steadily as [NaOH] is increased.

W. McC.

**Chemistry of insects. III. Wax of *Psylla bursi*.** B. K. BLOUNT (J.C.S., 1936, 1241—1242).—The wax, m.p. 89.6—90.1°, consists of an ester of the  $C_{30}$  acid with  $C_{30}$  alcohol, each component containing about 5% of the  $C_{28}$  compound. No paraffin is present.

F. R. S.

**Absorption spectra of kephalin, lecithin, and selected antigens.**—See this vol., 1178.

**Highly unsaturated fatty acids,  $C_{25}H_{40}O_2$  and  $C_{26}H_{42}O_2$ , in tunny oil.**—See this vol., 1230.

**Adsorption of proteins. Crystallised horse-haemoglobin. Horse serum-albumin.**—See this vol., 1202.

Flavins in the vitellin and shell of silkworm eggs and in the tegument of yellow silkworms. C. MANUNTA (Boll. Soc. ital. Biol. sperim., 1936, 11, 50—51).—The pigment of yellow silkworms is extracted (together with protein which is removed by  $\text{Na}_2\text{WO}_4\text{-AcOH}$ ) by 40% aq.  $\text{COMe}_2$  at 40—50° but not by abs.  $\text{COMe}_2$ ,  $\text{EtOH}$ , or  $\text{C}_6\text{H}_6$  (cf. A., 1932, 871). F. O. H.

Constituents of the retina. II. Visual purple. Reaction mechanism of the bleaching [of visual purple] by light. III. Vitamin-C content of the retina. O. BRUNNER and W. KLEINAU. IV. Flavins of the retina. O. BRUNNER and E. BARONI (Monatsh., 1936, 68, 244—246, 261—263, 264—273; cf. this vol., 97).—II. Visual purple is bleached by light at the same speed in the absence or presence of  $\text{O}_2$  or  $\text{Na}_2\text{S}_2\text{O}_4$ . Bleaching is thus not due to oxidation.

III. Determination of vitamin-C by 2:6-dichlorophenol-indophenol is best effected at exactly  $p_{\text{H}}$  2.5; glutathione and cysteine do not then interfere. Each retina of ox, pig's, and sheep's eyes contains 0.105, 0.026, and 0.04 mg., respectively, of -C. The titration is equally sharp at  $p_{\text{H}}$  7, so that SH-compounds are absent.

IV. Lactoflavin, lumiflavin, lumichrome, and creatinine (and, after decomp.,  $\text{NMc}_3$ ) are isolated from retina and choroid of ox and pigs' eyes. R. S. C.

Hæmatins of cytochrome-A. J. ROCHE and M. T. BENEVENT (Compt. rend., 1936, 203, 128—130).— $\text{C}_2\text{H}_5\text{N}$  extracts of various animal and vegetable tissues which contain cytochrome-A (I) or  $\text{-A}_1$  exhibit with  $\text{NaHS}$  or cystine an absorption band at 584—586  $m\mu$ , probably due to the hæmochromogen of (I). A and  $\text{A}_1$  do not co-exist, so their similar absorption at 585  $m\mu$  is probably due to a common group. Extracts of *B. coli communis*, rich in  $\text{A}_1$  and  $\text{A}_2$ , show also ill-defined bands at 600—605  $m\mu$  and 620—625  $m\mu$ . By a modification of Negelein's method (A., 1934, 96), a new hæmatin (II) is isolated from horse's heart-muscle, reduced to a hæmochromogen with bands at 580, 530, and 425  $m\mu$  (very similar to the bands of Warburg's "respiratory enzyme"), and converted by dil.  $\text{NaOH}$  into Negelein's hæmatin. (II) is probably the prosthetic group of cytochrome A and  $\text{A}_1$ . J. L. D.

Nature of the carbohydrate in lactalbumin. M. SØRENSEN (Compt. rend. Trav. Lab. Carlsberg, 1936, 21, No. 8, 123—128).—Fractionation of lactalbumin (I) gives one fraction very rich in carbohydrate. The nature and amount of this carbohydrate were determined by the orcinol method; it proved not to be galactose (II) as found by Sørensen and Haugaard (A., 1933, 731), but to be either lactose or, more probably, (II)+mannose, in which case the final (I) fraction contained 7.02% of carbohydrate. An explanation is given of the former error.

E. A. H. R.

Comparison between copper and iodometric methods for determining sugar in human milk. M. BERRY (Compt. rend. Soc. Biol., 1936, 122, 857—858).—The val. obtained by the iodometric is > that obtained by Bertrand's method, the deviations with human being > those with other milks. H. G. R.

Refraction of buffalo's and goat's milk sera obtained with copper sulphate. I. ZLATEFF (Z. Fleisch-Milchhyg., 1935, 45, 402—405; Chem. Zentr., 1935, ii, 3594).—The refractometer no. for Cu serum from buffalo's milk is 40.9—44.9 and for goat's milk 38—40.5; corresponding vals. for  $\text{CaCl}_2$  sera are 39.6—43.3 and 36.6—38.9. The influence of various factors on these vals. is discussed. H. N. R.

Active biological factor in cow's milk. R. SASAKI and N. ANDO (J. Agric. Chem. Soc. Japan, 1936, 12, 684—698).—The poor appearance of the fur of rats produced by excess of Ca in bread diets can be corr. by feeding cow's milk. J. N. A.

Transmission of vitamin-A from parents to young in mammals. V. Vitamin-A and carotenoid contents of human colostrum and milk. W. J. DANN (Biochem. J., 1936, 30, 1644—1651).—Single samples of human colostrum were obtained shortly after secretion commenced and those of early milk several days later. The diet was poor during pregnancy and liberal after delivery. The vitamin-A and carotenoid (I) contents of the colostrum were of the same order as in cows but could not be correlated with the age, number of birth, or length of time after birth until the colostrum was obtained. The -A and (I) contents of the early milk were for cow's milk. The -A content of colostrum was not increased by regular ingestion of cod-liver oil during pregnancy. The ratio of the amounts of -A in colostrum and early milk in 70% of cases was < 3 (small relative to the ratio for the cow). Colostrum can have no function in the provision of reserve supplies of -A at birth.

P. W. C.

Hæmostatic action of maternal milk. A. SOLE (Klin. Woch., 1935, 14, 1354—1359; Chem. Zentr., 1935, ii, 3402).—The coagulating principle is associated with the fat particles and separates with these. The prep. of an active milk powder is described. It has a local action only. A. G. P.

Chemical constitution of exudates and transudates. I. Protein and glucose. II. Calcium, sodium, and chlorine. E. STOLFI (Boll. Soc. ital. Biol. sperim., 1936, 11, 3—5, 5—8).—I. Polleri's work (Pathologica, 1926, 18, 287) is not confirmed. The lowest protein (I) content is found in the spermatocyst; in symptomatic hydrocele it is in essential hydrocele. The concn. of (I) in the plasma is slightly > that in the pleuritic and peritoneal exudates.

II. The Na contents are irregular. The Cl' in transudates is considerably, and in exudates slightly, > in the plasma. The Ca contents are diminished in exudates and transudates; in the latter the non-diffusible Ca is low. E. P.

Action of organ extracts on mesobilirubinogen (urobilinogen). I. Effect of aqueous glycerol extract of liver. G. OLIVA (Minerva med., 1935, II, 205—208). CH. ABS. (p)

Amino-acids and free choline in bile. E. F. W. MULLER (Z. physiol. Chem., 1936, 242, 201—203).—Fresh human bile treated with aq.  $\text{CuSO}_4$  and  $\text{Ba(OH)}_2$  yields glycine, tyrosine, lysine, and a mixture of valine and leucine together with some impure substances (including possibly arginine and histidine).

Bile also contains free choline ( $\leq 100$  mg. per 100 c.c.) in amount equiv. to the lecithin content.

W. McC.

**Metal content of gallstones and bile.** E. MULLER (Biochem. Z., 1936, 286, 182—185).—The ash of human bile contains Fe, Mn, Al, and Ni but, unlike gallstones, does not contain Cu, Pb, Cr, Zn, and Co.

P. W. C.

**New interpretation of results of the conventional titration of gastric juice.** L. MARTIN (Amer. J. Digest. Dis. Nutrition, 1934, 1, 330—332).—Titration of the juice to the lemon-yellow end-point of Topfer's indicator measures free HCl, acid combined with gastric proteins ( $\text{Cl}'$ ,  $\text{PO}_4'''$ ), and free  $\text{H}_3\text{PO}_4$ .

CH. ABS. (p)

**Antipeptic influence of gastric mucin.** E. A. ZAUS and L. S. FOSDICK (Amer. J. Digest. Dis. Nutrition, 1934, 1, 177—178).—The antipeptic action of the commercial mucin (I) disappears after 3 hr. incubation *in vitro*, but is increased by incubation at  $37^\circ$  in a pepsin solution. This is ascribed to hydrolysis of (I) with liberation of a substance resembling mucoitin- or chondroitin-sulphuric acid. The Ca salt of the last-named has a marked antipeptic effect.

CH. ABS. (p)

**Determination of sodium in urine by sedimentation.** E. BROUWER (Z. physiol. Chem., 1936, 241, 135—141).— $\text{PO}_4'''$  is removed from urine (2 c.c.) by shaking with CaO, and Na is pptd. by the method of Butler *et al.* (A., 1931, 1342) and determined with sufficient accuracy by a sedimentation procedure. The usual K contents do not interfere but control determinations must be made occasionally.

W. McC.

**Application of diphenylthiocarbazone (dithizone) to the determination of lead in urine.** F. MORRIS (Analyst, 1936, 61, 465—471).—500 c.c. of urine are treated with 10 c.c. of conc. aq.  $\text{NH}_3$ , and after keeping overnight, the ppt. is collected and ashed at  $500^\circ$ . The residue is dissolved in 20 c.c. of 10% HCl, filtered hot, and the filtrate treated with 10 c.c. of 60% aq.  $\text{NH}_3$  citrate and 5 c.c. of 10% aq. KCN, after which the solution is made just alkaline with aq.  $\text{NH}_3$ . It is shaken with 5-c.c. portions of a 0.05% solution of dithizone (I) in  $\text{CHCl}_3$  until the  $\text{CHCl}_3$  extracts show no pink colour after washing with 5 c.c. of 1% aq. KCN and 5 c.c. of 2% aq.  $\text{NH}_3$ . Free (I) is removed from the  $\text{CHCl}_3$  by repeated shaking with this solution, and finally the  $\text{CHCl}_3$  solution is shaken with 15 c.c. of 0.1N-HCl, the green colour produced, due to free (I), being compared colorimetrically with standards (cf. A., 1934, 381).

J. W. S.

**Determination of albumin in urine.** C. A. SAGASTUME and R. A. CRESPI GHERZI (Rev. Fac. Cienc. Quim. La Plata, 1935, 10, 7—10; cf. A., 1935, 884).—Albumin is pptd. by a solution of 50 g. of  $(\text{NH}_4)_2\text{SO}_4$ , 3 g. of PhOH, and 10 g. of sulphosalicylic acid in 100 g. of  $\text{H}_2\text{O}$ , and centrifuged (1500 r.p.m.) for 2 min. The method is more exact than that of Aufrecht.

F. R. G.

**Chemical basis of the Ehrlich diazo-reaction with urine.** III. P. SACHS (Z. physiol. Chem., 1936, 242, 19—22; cf. this vol., 502).—The fraction

of the crude dye (from the diazonium salt of 2:4- $\text{C}_6\text{H}_3\text{Cl}_2\cdot\text{NH}_2$  and urine) sol. in  $\text{Et}_2\text{O}$  and aq.  $\text{Na}_2\text{CO}_3$  and that ( $\text{C}_{12}\text{H}_8\text{N}_2\text{Cl}_4$ ) sol. in  $\text{Et}_2\text{O}$  but insol. in aq. NaOH and  $\text{Na}_2\text{CO}_3$  have no biological significance, the second probably being derived from the reagent. The fraction insol. in  $\text{Et}_2\text{O}$  when treated with fuming  $\text{HNO}_3$  and then with *p*-cresol (I) yields the original diazonium compound coupled with (I) and an orange-red substance,  $\text{C}_{28}\text{H}_{22}\text{O}_4\text{N}_2$ , m.p.  $200\text{--}201^\circ$ , containing a (I) residue. The corresponding substance  $\text{C}_{21}\text{H}_{16}\text{O}_3$  with which (I) couples to give the dye is probably not a pathological product.

W. McC.

**Ascites and retention of sodium.** W. KLODT and C. DIENST (Arch. exp. Path. Pharm., 1936, 182, 262—267).—The serous fluid of ascites has a mol. content of  $\text{Na}^+$   $>$  that of  $\text{Cl}'$ , the concns. being approx. equal to those in the serum. Palliative treatment includes restricted ingestion of  $\text{Na}^+$ . The phenomenon is due to diminished excretion of  $\text{Na}^+$  following disturbances of the  $\text{H}_2\text{O}$  threshold in cardiac and renal diseases.

F. O. H.

**Treatment of epidermophytosis of feet and hands with benzoic acid preparations.** H. O. LOOS (Arch. Dermatol. Syphilis, 1935, 173, 109—116; Chem. Zentr., 1935, ii, 3674).—The antimycotic action of Me, Et, Pr, and benzyl *p*-hydroxybenzoates increases in the order named. Nipasol (Pr ester) gives good results with mycosis of feet.

A. G. P.

**Effect of parathyroid hormone on heat stroke. Changes in blood-sugar and calcium and potassium contents of serum.** E. SANFILIPPO and S. RICCA (Biochim. Terap. sperim., 1935, 22, 411—420; Chem. Zentr., 1935, ii, 3669).—Hyperglycæmia following heat stroke in rabbits is more marked after pretreatment with parathyroid hormone. Treated animals showed lowered blood-Ca level in the initial and increased blood-K in the final phase.

A. G. P.

**Lipin-phosphorus content of hypertrophied heart and kidney in the rat.** S. LUDEWIG and A. CHANUTIN (J. Biol. Chem., 1936, 115, 327—332). The theory that the phospholipin (I) content of an organ is directly related to its activity is investigated. Hypertrophy of the heart or kidney in the rat, induced by unilateral nephrectomy, is not associated with an increased % of (I) in these organs.

H. D.

**Magnesiæmia in hypothalamic-hypophyseal diseases. I. Blood-magnesium. II. Parallelism between hypermagnesiæmia and hyperprolactinuria in hypophyseopathy. III. Variations in magnesiæmia and prolactinuria on X-irradiation of the pituitary gland in hyperpituitarism.** L. CANNAVO and G. FRADDA (Boll. Soc. ital. Biol. sperim., 1936, 11, 194—196, 196—197, 198).—I. Hyperpituitarism in man is accompanied by hypermagnesiæmia and hypopituitarism by occasionally slight hypomagnesiæmia. The P level follows a parallel course whilst Ca is approx. const.

II. Hypermagnesiæmia is accompanied by increased levels of gonadotropic hormone in blood and urine.

III. The abnormally high serum-Mg and urinary prolactin levels are diminished (cf. A., 1935, 543).

F. O. H.

**Cirrhosis of the liver.** I. Etiology, symptomatology, liver-function tests and gastric juice findings. II. Calcium, total proteins, sugar, and chloride distribution in various body-fluids. C. F. WANG (Chinese Med. J., 1936, 50, 891—902, 903—910).—II. The average serum-Ca (8.56 mg. per 100 c.c.) is < normal. The sugar contents of ascitic, pleural, and oedematous fluids are > those of the blood and cerebrospinal fluid, these latter being within the normal range. W. O. K.

**Fluorine as a specific for the parathyroid.** M. CALLAM (Münch. med. Woch., 1935, 82, 1534—1535; Chem. Zentr., 1935, ii, 3400).—Use of 1% solution of NaF in certain diseases is described. A. G. P.

**Calcium and phosphorus metabolism in pituitary basophilism.** R. H. FREYBERG and R. L. GRANT (Arch. Int. Med. 1936, 58, 213—228).—The P and Ca metabolism was not characteristic of hyperparathyroidism, but there was a low concn. of P in the serum, and a low urinary and high faecal excretion of P. Sufficient Ca and P was not absorbed to allow their retention, although there was a great need of  $\text{Ca}_3(\text{PO}_4)_2$ . Administration of vitamin-D hardly affected absorption and retention of Ca, but there was good utilisation of Ca when it was injected intravenously. J. N. A.

**Glycæmia following scalding and traumatic shock.** G. STOLFI (Boll. Soc. ital. Biol. sperim., 1936, 11, 8—11).—Traumatic shock or scalding in rabbits produces hyperglycæmia. F. O. H.

**Cause of hyperglycæmia following traumatic shock.** I. Blood-glycolysis. II. Liver-glycogen and cellular oxidation. G. STOLFI (Boll. Soc. ital. Biol. sperim., 1936, 11, 106—107, 107—109).—I. Traumatic shock only slightly diminishes blood-glycolysis.

II. Cellular dehydrogenation diminishes in brain and heart but increases in liver, kidney, and muscle (rabbit). Hepatic glycogenolysis, however, is the main cause of the hyperglycæmia. F. O. H.

**Effect of alkaline therapy for peptic ulcer on utilisation of dietary iron in regeneration of hæmoglobin.** F. KELLOGG and S. R. METTIER (Arch. Int. Med., 1936, 58, 278—284).—No significant increase in hæmoglobin (I) occurred during alkaline therapy and restriction of Fe intake, but addition of foods rich in Fe increased the no. of erythrocytes, but not (I). Cessation of alkaline therapy caused an increase in (I). Alkalinisation of the upper part of the gastro-intestinal tract interferes with the utilisation of dietary Fe for the synthesis of (I), but not with the material needed for formation of erythrocytes. J. N. A.

**Relations between [mitogenetic] radiation, catalase action, and respiration intensity during development of *Bombyx mori*, L.** K. YAMAFUGI and S. GORO (Bull. Agric. Chem. Soc. Japan, 1936, 12, 90—93).—During embryonic evolution there is no exact parallel between respiration intensity and catalase (I) activity. The mitogenetic radiation from the egg is connected with colour changes in the egg, and also with a strong (I) activity and a weak respiration intensity.

Radiation is a min. at the stages when the colour of the egg is still yellow, and the (I) content low and when the worm emerges and respiration and (I) activity reach a max. The respiration of the cocoon is very small compared with that of the larva and moth, but the (I) activity is much greater, and the mitogenetic radiation is also at a max. During the change of larva to moth, the radiation is intermittent. J. N. A.

**Respiration of brain.** T. F. DIXON and A. MEYER (Biochem. J., 1936, 30, 1577—1582).—The  $\text{O}_2$  uptake of the minced striate body, globus pallidus, cerebellar cortex, cornu ammonis, hypothalamus, and medial parts of the thalamus of ox brain is scarcely if at all increased by addition of glucose or lactate but is constantly and greatly increased if slices of these parts are used. The metabolic activity of the cerebellar cortex is > that of any other part of the brain. W. McC.

**Production of a [growth]-inhibiting substance in tissue cultures.** L. NATTAN-LARRIER and L. GRIMARD (Compt. rend. Soc. Biol., 1936, 122, 1187—1190).—Development of old cultures is arrested by the production of an inhibiting substance which can act *in vivo*. H. G. R.

**Relation between the minimum protein requirement and the base content of human diet.** C. ROSE (Z. ges. exp. Med., 1935, 96, 793—798; Chem. Zentr., 1935, ii, 3403).—The N balance was positive on a basic and negative on an acidic diet. An adequate base content in the food is necessary for the effective utilisation of protein. A. G. P.

**Effect of diet on phosphate compounds in the liver of dogs.** E. FLOCK, J. L. BOLLMAN, and F. C. MANN (J. Biol. Chem., 1936, 115, 179—199).—A method for the separation and determination of total, acid-sol., phospholipin-, and residual  $\text{PO}_4'''$  in hepatic tissue is described. The total  $\text{PO}_4'''$  in livers of normal dogs on a regular kennel diet varied from 241 to 318 mg. of P per 100 g. of moist tissue. Using a standard balanced diet, the range was 226—270 mg. The acid-sol.  $\text{PO}_4'''$  was similar for the two diets, whilst diets rich in protein, carbohydrate, or fat and fasting gave normal  $\text{PO}_4'''$  vals., but a high-fat diet for < 20 days reduced the total  $\text{PO}_4'''$ . The greatest decrease occurred in the acid-sol. (especially glycerophosphoric acid and an extremely sol. unknown  $\text{PO}_4'''$ ), and the smallest in the phospholipin fraction. With a const. diet, the composition of the livers of individual dogs at different times remained approx. const. If a diet high in fat be replaced by one high in carbohydrate, the normal composition of the liver was quickly restored. J. N. A.

**Protein lost by the various organs and tissues of the body during a fast.** T. ADDIS, L. J. POO, and W. LEW (J. Biol. Chem., 1936, 115, 111—116).—The % protein-loss (in rats fasted for 1 week) was distributed as follows, the proportion of the original protein being in parentheses: muscle, skin, and skeleton 62 (8), liver 16 (40), alimentary tract, pancreas, and spleen 14 (18—28), blood 6 (18—28), kidneys 1 (18—28), heart 0.5 (18—28), other organs 0.5. The testicles and adrenals lost no protein,

whilst the prostate and seminal vesicles lost 29 and the brain 5% of their initial protein content.

H. G. R.

**Protein-loss from liver during a two-day fast.** T. ADDIS, L. J. POO, and W. LEW (J. Biol. Chem., 1936, 115, 117—118; cf. preceding abstract).—The liver (rat) lost 20% of its original protein, whilst all other organs and tissues combined lost only 4%. This supports the hypothesis that the liver contains a store of reserve protein.

J. N. A.

**Photosensitisation of animals in S. Africa.** VIII. Biological formation of phyloerythrin in digestive tracts of various domesticated animals. J. I. QUIN, C. RIMINGTON, and G. C. S. ROETS (Onderstepoort J. Vet. Sci., 1935, 4, 463—478).—Formation of phyloerythrin (I) from chlorophyll (II) in the digestive tract is due to symbiotic infusoria and bacteria. The (I) content of sheep faeces is probably related to the (II) content of the food plant.

CH. ABS. (p)

**Synthesis of uric acid in the avian organism: hypoxanthine as intermediary metabolite.** N. L. EDSON, H. A. KREBS, and A. MODEL (Biochem. J., 1936, 30, 1380—1385).—In pigeons two tissues are necessary for uric acid (I) synthesis. 30% of the  $\text{NH}_3$  which is bound in presence of lactate and pyruvate by the liver appears as hypoxanthine (II) and is isolated as such. In the kidney and pancreas (II) is oxidised to (I), xanthine oxidase (III) acting as catalyst. The kidney and pancreas do not bind  $\text{NH}_3$  and the amount of (I) produced by liver, kidney, and pancreas separately is small. Liver produces (I) in the absence of kidney when (III) (from milk) is added. Probably in other birds also (II) is an intermediate in (I) production.

W. McC.

**Degradation of dimethylaniline in herbivora.** F. HORN (Z. physiol. Chem., 1936, 242, 23—28; cf. this vol., 514).—In rabbits  $\text{NPhMe}_2$  subcutaneously injected is converted into  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{NHMe}$ , which is excreted conjugated with glucuronic acid in the urine. Possible  $\text{NHPHMe}$  is an intermediate product in the process and small amounts of it are sometimes found. Administration of  $\text{NPhMe}_2$  does not lead to production of  $\text{NPhMe}_2\text{O}$  or of methæmoglobin.

W. McC.

**Post-mortem transformation of barbituric derivatives into hydrocyanic compounds.** P. R. ORELLA (Rev. Fac. Cienc. Quím. La Plata, 1935, 10, 51—60).—Contrary to Kohn-Abrest *et al.* (A., 1930, 369) when veronal, luminal, or prominal was orally administered to dogs, no HCN or HCN derivatives were detected in the organs or viscera. The presence of CNS' in man is attributed to the use of mustard or tobacco.

F. R. G.

**Cholesterol feeding and fat metabolism.** R. P. COOK (Biochem. J., 1936, 30, 1630—1636).—With rats maintained on synthetic diets, cholesterol (I) feeding causes a decreased growth rate and a fatty liver only when the diet contains fat. With fat-free diets there is no effect due to absence of absorption. Guinea-pigs are very susceptible to the action of (I) and fatty livers are produced without adding fat to the stock diet. There is a marked decrease in the

depot fat, the action of (I) being in part the mobilisation of fat in the liver.

P. W. C.

**Respiration and ketogenesis in the "cholesterol" fatty liver.** R. P. COOK and N. L. EDSON (Biochem. J., 1936, 30, 1637—1639).—Rats given a fat-free diet + cholesterol (I) for short periods failed to develop fatty livers. The livers gave normal respiration vals. and on adding  $\text{PrCO}_2\text{Na}$  (II) the normal  $\text{O}_2$  uptake and ketone (III) formation. Guinea-pigs also presented a normal metabolism. After feeding (I) for longer periods to rats the liver tissue had a significantly lower respiration both in presence and absence of (II), whilst with guinea-pigs there was no significant change of respiration but (III) formation in presence of (II) was decreased. Spontaneous (III) formation in (I) fatty liver is < in livers of rats starved for 24 hr. The changes in respiration and (III) formation in these fatty livers are small.

P. W. C.

**Synthesis of cholesterol in living organisms.** H. L. BROSE (J. Cancer Res. Comm. Sydney, 1936, 7, 134—136).—A discussion of the *in vivo* synthesis of cholesterol from oleic acid (cf. Minovici *et al.*, A., 1934, 552).

W. O. K.

**Biological oxidation of dibasic and  $\omega$ -oxidation of monobasic fatty acids.** F. P. MAZZA (Boll. Soc. ital. Biol. sperim., 1936, 11, 143—145).—Org. dibasic acids [saturated (excepting glutaric) and unsaturated (with certain exceptions)] are readily oxidised (without production of  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{H}$ ) by liver and kidney tissues, the latter being more active in  $\omega$ -oxidation (cf. Verkade and Lee, A., 1935, 242, 390) of monobasic acids and their esters. Suberic acid appears to yield a  $\gamma$ -diketone.

F. O. H.

**Biological oxidation of saturated dibasic fatty acids.** F. P. MAZZA (Boll. Soc. ital. Biol. sperim., 1936, 11, 157—158).— $\beta\beta'$ -Diketoadipic acid is oxidised and decarboxylated by liver and kidney tissue, the latter producing traces of  $\text{H}_2\text{C}_2\text{O}_4$ ; adipic acid yields traces of  $\text{Ac}_2$  with kidney but with neither tissue is  $\text{H}_2\text{C}_2\text{O}_4$  formed. The processes are discussed with reference to  $\beta$ - and  $\omega$ -oxidation.

F. O. H.

**Nutritive value of pentosan. III. Decomposition of xylan by intestinal bacteria.** H. IWATA (J. Agric. Chem. Soc. Japan, 1936, 12, 587—594).—Micro-organisms in the alimentary tract of man and higher animals decompose xylan (I) into xylose, lactic acid,  $\text{PrCO}_2\text{H}$ ,  $\text{AcOH}$ , and  $\text{HCO}_2\text{H}$ , together with  $\text{CO}_2$  and traces of  $\text{H}_2$ .  $\text{EtOH}$ ,  $\text{MeCHO}$ , and  $\text{CH}_4$  are not produced. The protein synthesised by these organisms from (I) and  $\text{NH}_4$  phosphate is similar to a plant-protein.

J. N. A.

**Assimilation of carbohydrates (starch and its hydrolysis products) in infants under six months on an artificial or mixed diet.** P. ARMAND-DELILLE, MENTZER, and URBAIN (Compt. rend. Soc. Biol., 1936, 122, 1212—1213).—Cooked starch, up to 30 g. per day, is assimilated by infants of 3—6 months.

H. G. R.

**Utilisation of sugars in experimental diabetes.** T. CARN and J. HOUGET (Compt. rend., 1936, 203, 130—132; cf. this vol. 749).—The vastus externus

of pancreatectomised dogs when tetanised has a normal content of reducing substances and lactic acid (I). The blood- and liver-(I) are normal, but the liver-sugar is diminished. After exercise, muscle-glucose and -(I) decrease and blood- and liver-(I) increase. With diabetic dogs, the peripheral utilisations of glucose and carbohydrate storage in muscle are normal but glycogen storage in the liver is very slight.

J. L. D.

#### Action of metals on carbohydrate metabolism.

I. U. SAMMARTINO (Arch. Farm. sperim., 1936, 61, 209—236).—The blood-sugar of normal rabbits is unaltered by intravenous injection of aq. NaCl; that of aq. chlorides of K, Rb, Cs, or Sr has an irregular effect, either increasing or decreasing the level, whilst that of aq. LiCl, CaCl<sub>2</sub>, and, more consistently, BaCl<sub>2</sub>, produces hypoglycaemia.

F. O. H.

Combustion of ethyl alcohol during perfusion of the liver. N. FIESSINGER, H. BÉNARD, J. COURTIAL, and L. DERMER (Compt. rend. Soc. Biol., 1936, 122, 1255—1258).—After a rapid decrease, due to diffusion, EtOH destroyed  $\propto$  the time and is not affected by the addition of 2:4-dinitrophenol. Addition of KCN inhibits the combustion, which recommences at a lower rate on adding Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>.

H. G. R.

Oxidation of the methyl group in the animal body.—See this vol., 1231.

Metabolism of iodine. III. Uptake from surrounding air by man. H. LÖHR (Arch. exp. Path. Pharm., 1936, 182, 132—140; cf. this vol., 358).—The blood-I of men in an atm. containing I (e.g., the air near patients painted with tincture of I) increases up to 6—7 times ( $167.2 \times 10^{-6}\%$ ) the normal val. within 1 hr.; the absorption is mainly through the lungs, that through the skin being much smaller. The increase persists for approx. 5 days.

F. O. H.

Chemical processes during cell division. II. Nature and kinetics of the reaction between -SH groups and moniodoacetic acid. L. RAPKINE (J. Chim. phys., 1936, 33, 493—506; cf. A., 1931, 115; 1933, 1039).—The -SH of denatured reduced egg-white (I) reacts quantitatively with 1 mol. of CH<sub>2</sub>I-CO<sub>2</sub>Na (II), liberating 1 HI. -SH determined by a direct method, in which the indicator (Na nitroprusside) is added 30—40 min. after mixing (I) with (II) at 50° and  $p_H$  7.5, accords with the val. given by Hopkins' method. Under similar conditions, the rate of reaction of (II) increases in the order (I) < glutathione (III) < cysteine and the rates increase with rise of temp. The reaction with (III) increases rapidly as the  $p_H$  is raised to >6.

J. G. A. G.

Right vagus nerve and hypoglycaemic action of ultra-violet irradiation. E. MARTINI and E. RONCALLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 77—79).—Section of the right vagus or sciatic nerve in rabbits depresses the hypoglycaemic action of irradiation (this vol., 238).

F. O. H.

Glycaemia and ketosis in rabbits due to X-ray lesions of the anterior pituitary lobe. L. CANNANO and S. LA MONACA (Boll. Soc. ital. Biol. sperim., 1936, 11, 35—36).—Cell destruction of the anterior

lobe due to intensive X-irradiation of the pituitary produces a slight hyperglycaemia but the alimentary glycaemia curve is unchanged. The effect on ketonuria is variable (cf. A., 1935, 543).

F. O. H.

Effect of short electric waves on sterol colloids. W. M. MALISOFF and F. A. STENBUCK (J. Biol. Chem., 1936, 115, 87—91).—Waves of the order of 5 m. have a coarsening effect on colloidal preps. of cholesterol or its acetate which is independent of temp. and increases with age of the colloid and time of exposure.

H. G. R.

Action of ultra-violet rays on starch solution. T. ISEMURA (J. Chem. Soc. Japan, 1935, 56, 772—778).—The initial stage of decomp. of starch by diastase was hydrolysis of amylose and amylo-pectin. Decomp. by exposure to ultra-violet light involved oxidation as well as hydrolysis of amylophosphoric ester.

CH. ABS. (p)

Biochemical and biological changes produced by high pressures. M. A. MACHEBŒUF and J. BASSET (Bull. Soc. Chim. biol., 1936, 18, 1181—1191).—The cells of higher animals and bacteria are killed, enzymes are inactivated, certain cancer cells lose their power of transplantation, certain immunity reactions are destroyed, and serum-globulin is coagulated by pressures up to 20,000 atm. The pressures required to inactivate bacteria may form a basis for their differentiation.

H. D.

Influence of hydrogen-ion concentration and of salinity on eggs of *Eugraulis encrasicholus*, L. S. S. ELIZAROVA (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 255—260).—In variety *maeoticus* eggs survive a salinity <5.36 g. per 1000 g. and  $p_H$  >6.52. Eggs of variety *ponticus* develop in the range 8—21 salinity and  $p_H$  6.9—8.9.

A. G. P.

Adaptation of cutaneous tactile receptors. IV. Electrolyte content of frog skin. M. A. RUBIN. V. Release of potassium from frog skin by mechanical stimulation. H. HOAGLAND and M. A. RUBIN. VI. Inhibitory effects of potassium and calcium. H. HOAGLAND (J. Gen. Physiol., 1936, 19, 935—937, 939—942, 943—950).—IV. The skin of *Rana pipiens* contains K 132, Na 91, Ca 302, Mg 4.4, Cl 172, S 33, and P 337 mg. per 100 g. of wet tissue.

V. K is liberated from the epithelial cells of frog skin on stimulation by an interrupted air-jet; Ca<sup>++</sup>, PO<sub>4</sub><sup>'''</sup>, and Cl<sup>'</sup> are not liberated under these conditions.

IV. The adaptation to stimulation by an interrupted air-jet of single freely branching axon endings in frog skin is hastened by Ringer's solutions containing 15-fold excess of K or Ca. K acts more rapidly than Ca, and the K effect, but not the Ca effect, is reversible in normal Ringer's solution. Recovery from Ca inhibition can be effected by K-rich solutions. K, but probably not Ca, is involved in the adaptation of the tactile nerve endings in frog skin.

F. A. A.

Absorption of drugs from human skin. A. R. BLISS, jun. (J. Amer. Pharm. Assoc., 1936, 25, 694—701).—Inunction with ointments containing Me salicylate, I, I+KI, or KI is followed by absorption of the drug (as indicated by presence in the urine)

to a varying extent. I is not absorbed from aq. preps. nor is quinine hydrochloride from ointments. The fatty base of the ointment has no influence on absorption. F. O. H.

**Permeability of tissue cells.** H. GROSSFELD (Biochem. Z., 1936, 286, 193—195).—Dil. aq.  $\text{NH}_3$  permeates normal tissue cells (heart, stomach, liver, etc. of chick embryos) *in vitro* quickly,  $\text{NaHCO}_3$  much more slowly, and  $\text{NaOH}$  and  $\text{KOH}$  hardly at all.  $\text{NH}_4\text{Cl}$  and  $\text{Na}_3\text{PO}_4$  in presence of Ringer's solution permeate very slowly but in absence of Ringer's solution very quickly and cause considerable swelling. In absence of Ringer's solution, urea permeates much more quickly into the cells than does glucose. P. W. C.

**Calcium, phosphorus, and the alkali reserve in rachitic osteopathy produced by strontium.** G. NATUCCI (Biochim. Terap. sperim., 1935, 22, 385—389; Chem. Zentr., 1935, ii, 3671).—Oral administration of Sr lactate to young rabbits produced changes in bones of a rachitic nature, hypercalcaemia, and a lowering of the P level and alkali reserve of the blood. A. G. P.

**Relationship of tissue-iodine to glycogen.** A. STURM and H. ERTNER (Biochem. Z., 1936, 286, 204—212).—During electric stimulation of rabbit muscle, glycolysis is accelerated by I', inorg. I taking part in glycogen degradation and becoming organically bound as  $\text{H}_2\text{O}$ -sol. protein-I (I). The increase of liver-glycogen during the action of insulin is accompanied by a decrease of (I) and an increase of inorg. I. The probable close relationship of (I) with the thyroglobulin of thyroid gland is discussed. P. W. C.

**Relation between chemical constitution and physiological action of organic compounds. I. Action of benzene, toluene, xylene, and mesitylene on white mice.** V. VLASSOPOULOS (Praktika, 1935, 10, 32—41; Chem. Zentr., 1935, ii, 3405—3406).—Physiological action (reflex stimulus, convulsions, paralysis) is weaker as the mol. is more symmetrical, e.g.,  $\text{PhMe} > \text{C}_6\text{H}_6$ ,  $\text{PhMe} > \text{xylene} > \text{mesitylene}$ . A. G. P.

**Action of camphor on the heart system.** B. KADYKOV and I. LEWIN (Arch. int. Pharm. Ther., 1935, 50, 298—314; Chem. Zentr., 1935, ii, 3542).—A. G. P.

**Action of octinum in increasing blood pressure.** E. ETTINGER and L. POPPER (Klin. Woch., 1935, 14, 575—576; Chem. Zentr., 1935, ii, 3406).—The mechanism of the action of octinum (methyl-octenylamine) is examined. A. G. P.

**Skatole and tissue cultures.** J. VERNE and P. KUBIKOWSKI (Compt. rend. Soc. Biol., 1936, 122, 1155—1156).—Skatole, at very low concn., augments the growth of fibroblasts and renal cells. H. G. R.

**Blood-sugar and glutathione content of blood and tissues after administration of glutathione.** J. DRISCH (Arch. exp. Path. Pharm., 1936, 182, 301—312).—Parenteral administration of glutathione (I) temporarily increases the blood-sugar in rabbits, the injected (I) being mostly excreted (partly reduced) within 15 min. The content of oxidised (I) in the lungs increases and that of reduced (I) in the intestine

decreases; the muscle content is unaffected whilst the liver shows a slight decrease. Continuous injection is not followed by storage in the organs. (I) has no significant effect on the action of insulin or adrenaline; it probably directly affects blood-glycolysis. F. O. H.

**Action of phloridzin on muscular glycogenolysis.** J. K. PARNAS, W. MEJBAUM, and B. SOBCHUK (Compt. rend. Soc. Biol., 1936, 122, 1148—1152).—Phloridzin suppresses primarily the formation of hexose monophosphate and also the oxidation-reduction of phosphotriose. H. G. R.

**Chemistry, pharmacology, and chemotherapy of thiazyl substances.** E. MENEGHETTI (Boll. Soc. ital. Biol. sperim., 1936, 11, 189—191).—A preliminary discussion. F. O. H.

**Theory and pharmacological and chemotherapeutic action of auxochromes. I. B. BREYER** (Boll. Soc. ital. Biol. sperim., 1936, 11, 191—194).—A résumé of the theories of Diltthey and Wizinger (A., 1926, 1163; 1927, 764; 1928, 627; 1932, 1127) and a discussion of their possible significance in biological action. F. O. H.

**Chemical constitution and pharmacological action. Quinoline-4-carboxylic acids.** S. BERLINGOZZI and G. DONATELLI (Boll. Chim. farm., 1936, 75, 381—389).—Isatoic acid with  $\omega$ -anilino-acetophenone in  $\text{EtOH-NaOH}$  affords 3-anilino-2-phenylquinoline-4-carboxylic acid (cf. A., 1924, i, 314, 1345; 1927, 674, 1086, 1087). The action of this and other derivatives (*ibid.*) of quinoline-4-carboxylic acid (I) on blood- and urine-uric acid indicates a slight increase of uric acid excretion due to (I) following substitution of OH or  $\text{NH}_2$  at 3 and a decrease following that of OPh and  $\text{C}_6\text{H}_5\text{NHAc}$  at 3 and 6, respectively. F. O. H.

**Effect of diethylaminomethylbenzdioxan on diuresis.** E. ZUNZ and F. JOURDAN (Ann. physiol. physicochim Biol., 1934, 10, 880—886; Chem. Zentr., 1935, ii, 3406).—The diuretic action of  $\text{H}_2\text{O}$ ,  $\text{NaCl}$ , and urea is restricted. A. G. P.

**Action of diethylaminomethyl- (F. 883) and piperidomethyl-3-benzdioxan on the circulatory system.** G. DE VLEESCHOUWER (Arch. int. Pharm. Ther., 1935, 50, 251—295; Chem. Zentr., 1935, ii, 3539—3540).—Experiments with chloralised dogs are recorded. The mutual effects of these and other drugs are examined. A. G. P.

**Toxicity and antipyretic action of *d*-glucono-*p*-phenetidine.** H. A. BRAUN and G. F. CARTLAND (J. Amer. Pharm. Assoc., 1936, 25, 615—618).—*d*-Glucono-*p*-phenetidine (I) has a toxicity < that of acetophenetidine (II), the min. lethal dose in rats being >50 and 2 g. per kg., respectively. Methæmoglobin formation occurs with (II) but not (I). The antipyretic action of (I) in febrile rabbits is < that of (II) (cf. Hamburger, A., 1934, 691). F. O. H.

**Action of (A) arsenicals on glycolysis of the isolated rabbit's heart, (B) atoxyl on enzymic glucose degradation, and (C) glucose on lipin degradation due to atoxyl in the artificially-circulated heart.** B. TANZI (Boll. Soc. ital. Biol. sperim., 1936, 11, 129—130, 131, 131—132).—(A)

0.002*M*- $\text{Na}_3\text{AsO}_4$  or 0.005*M*-atoxyl diminishes whilst 0.01*M*- $\text{Na}_3\text{AsO}_4$  increases lactic acid (I) production, probably respectively due to inhibition and stimulation of glycolysis.

(b) Atoxyl (0.005*M*) in the perfusing glucose-Ringer's solution depresses the aerobic or anaerobic formation of (I).

(c) Glucose does not influence the decomp. of lipins due to atoxyl. F. O. H.

**Experimental anæmias and their suitability for the assay of anti-anæmic preparations. III. Collargol-saponin anæmia in rabbits for the assay of injected liver extracts.** P. GOTTLIBE (Arch. exp. Path. Pharm., 1936, 182, 91—97; cf. this vol., 1014).—Active liver preps. injected into rabbits in which anæmia has been induced by injection of collargol-saponin increase the erythrocyte count and hence such animals are suitable for the assay of anti-anæmic preps. F. O. H.

**Influence of oxidation-reduction dyes on conditions of disturbed respiration. I. Thionine and methæmoglobin[forming] poisons.** F. HAUSCHILD (Arch. exp. Path. Pharm., 1936, 182, 118—131).—The pharmacology of thionine (I) was investigated in rats; the min. lethal dose is 10 mg. per 100 g. body-wt. whilst luminal has an antagonistic action. (I) inhibits the toxicity of methæmoglobin-forming (e.g.,  $\text{NaNO}_2$ ,  $\text{NH}_2\text{Ph}$ ,  $\text{NHPh}\cdot\text{OH}$ ) poisons, probably by acting as  $\text{O}_2$ -transporter in place of the affected hæmoglobin. F. O. H.

**"Vagotropine" of Viale. (A) Origin. (B) Nature. (C) Relation to vagotropic substance of Loewi and acetylcholine.** B. BARTOLINI (Boll. Soc. ital. Biol. sperim., 1936, 11, 83—85, 86—88, 88—91).—(A) Vagotropine (I) is of uniform occurrence in the dog's organs.

(b) (I) is org., sol. in EtOH, not extracted from serum by  $\text{CHCl}_3$  or  $\text{Et}_2\text{O}$ , and does not occur in filtrates from pptn. of sera by  $\text{CCl}_3\cdot\text{CO}_2\text{H}$  or phosphotungstic acid; a non-protein character, however, is indicated by its non-pptn. by tannic acid.

(c) The vagotropic substance of Loewi, but not (I), is probably identical with acetylcholine (cf. A., 1929, 1326). F. O. H.

**Intravenous administration of egg-lecithin and carbohydrate metabolism.** M. TESTOLIN and A. CHINAGLIA (Rass. Clin. Terap., 1935, 34, 124—137; Chem. Zentr., 1935, ii, 3405).—Egg-lecithin increases carbohydrate tolerance, and thus facilitates the utilisation of sugar by increasing both consumption and storage by the liver. A. G. P.

**Specific depressor substance of secretions of the human prostate and seminal vesicles.** U. S. VON EULER (Klin. Woch., 1935, 14, 1182—1183; Chem. Zentr., 1935, ii, 3535).—The substance "prostaglandin" is isolated from dialysed EtOH extracts of the tissues or secretions. It is acidic and differs in some respects from the active material previously isolated from other body-fluids. Its physiological activity is unaffected by atropine. A. G. P.

**Alkyl- and aryl-amides and -carbamides as hypnotics.**—See this vol., 1237.

**Antagonism of narcotics to cardiazole.** O. GROS and H. T. A. HAAS (Arch. exp. Path. Pharm., 1936, 182, 348—362).—The action of various narcotics in diminishing the lethal effect of administration of 15 mg. per 100 g. of cardiazole to rats was investigated. The ratio of narcotic dose (from the "side-position" reaction) to protective dose is 4—6 for all the narcotics examined. The anomalous behaviour of chloral hydrate and avertin is discussed. F. O. H.

**Pernocton-urethane. Therapy of combination of hypnotics.** G. PIOTROWSKI (Arch. exp. Path. Pharm., 1936, 182, 243—248).—Pernocton (I) and urethane (II) produce hypnosis (i.e., sleep for 30—45 min.) with subcutaneous injection of respectively 0.045—0.050 and 0.9—1.20 g. per kg. in rabbits and guinea-pigs. The effect of mixtures of (I) and (II) is purely additive (cf. Lendle, A., 1927, 1219), hence both have the same site of action (pons and mid-brain). F. O. H.

**Toxicity of barbital derivatives.** I. JONES and E. V. LYNN (J. Amer. Pharm. Assoc., 1936, 25, 597—601).—The min. lethal doses of amytal, barbital, dial, neonal, pentobarbital, phanodorm, and phenobarbital, administered orally and intraperitoneally to rabbits, are tabulated. F. O. H.

**Increased veronal excretion due to alkalis.** H. SALZER and R. FISCHER (Arch. exp. Path. Pharm., 1936, 182, 170—177).—The total excretion of veronal administered to rabbits is increased by intravenous injection of  $\text{NaHCO}_3$ , which raises the urinary  $p_{\text{H}}$  from 4.5 to 7—8. The mechanism is probably one of inhibition of tubular re-absorption in the kidneys and increased excretion of the Na salt. The toxicity is also correspondingly modified. F. O. H.

**Local anaesthetics containing the morpholine ring.**—See this vol., 1274.

**Quantitative relationships between the basic and other components of pancreatic secretion.** R. K. S. LIM, S. M. LING, A. C. LIU, and I. C. YUAN (Chinese J. Physiol., 1936, 10, 475—491).—Data are given for the total base,  $\text{HCO}_3^-$  and  $\text{Cl}^-$  contents,  $p_{\text{H}}$  and vol. of the pancreatic juice secreted by dogs under chloralose anaesthesia after stimulation by the introduction of aq. glucose into the duodenum. The results indicate that the juice consists of three independent secretions containing, respectively, (a) 0.174*N*- $\text{NaHCO}_3$ , (b) 0.174*N*- $\text{NaCl}$ , and (c)  $\text{HCl}$ , mucus, and enzymes. The chief constituent is (a) along with a proportional quantity of (b) and a small but const. val. of (c). The pancreatic  $\text{NaHCO}_3$  and gastric  $\text{HCl}$  are both secreted at cons. isosmotic with the blood. W. O. K.

**Dependence of infiltration of anaesthetics on their chemical nature or on composition of biological substrate.** A. PATANIA (Boll. Soc. ital. Biol. sperim., 1936, 11, 202—204).—The rate of absorption of anaesthetics by the skin of amphibia depends on the chemical nature of the anaesthetic. F. O. H.

**Assay of aphrodisiacs by Glaser and Haempel's fish method.** E. GLASER and A. KONYA (Arch. exp. Path. Pharm., 1936, 182, 219—238).—The

activities of various preps. (e.g., yohimbine, cantharidin) as indicated by tests on fish (A., 1932, 308) and their relation to sex-hormonal action are discussed.

F. O. H.

**Folinerin, a new cardiac drug from leaves of *Nerii oleander*.** F. FLURY and W. NEUMANN (Klin. Woch., 1935, 14, 562—564; Chem. Zentr., 1935, ii, 3542).—This cryst. glucoside (low mol. wt.) exerts the same action on the frog heart as does digitalis, is less sensitive to acids, permanent in storage, and easily resorbed.

A. G. P.

**Heart treatment with the pure glucoside of *Scilla*.** F. BACH and A. BERR (Deut. med. Woch., 1935, 61, 1591—1594; Chem. Zentr., 1935, ii, 3406).—The glucoside is effective on digitalis-refractory hearts.

A. G. P.

**Pigeon bio-assays and diuretic tests of digitalis substances.** A. J. LEHMAN (J. Amer. Pharm. Assoc., 1936, 25, 611—615).—Min. emetic and fatal doses (pigeon) and min. fatal doses (cat) are tabulated. Cessation of urinary flow in pigeons is unsatisfactory as a method of assay.

F. O. H.

**Potency of eleven crystalline cardiac principles from plants.** K. K. CHEN, A. L. CHEN, and R. C. ANDERSON (J. Amer. Pharm. Assoc., 1936, 25, 579—590).—The potency of convallatoxin,  $\beta$ -antiarin, ouabain, cymar, scillaren-A, digoxin, digitoxin, erythrophlein sulphate, thevetin (cat unit  $0.92 \pm 0.035$  mg. per kg., i.e., > that previously reported), uzarin, and gitoxin were determined by the cat unit, frog min. systolic dose, and cat min. emetic dose. Emetic action is not related to cardiac action. Relationship between chemical structure and pharmacological activity is discussed.

F. O. H.

**Evaluation of cardio-active glucosides by means of frogs.** K. FROMHERZ (Arch. exp. Path. Pharm., 1936, 182, 55—71).—The use of standard preps. of *g*- (I) and *k*-strophanthin (II), convallatoxin (III), digitoxin, and total-glucoside extracts of *Digitalis* and *Adonis* was investigated by the lethal-dose method in 8500 frogs. With different standards, an error up to 25—33% (average  $\pm 10\%$ ) occurs, but by using a definite standard the error is diminished, e.g., (I) to (II) and (III) to (II) give respective average errors of  $\pm 6.5$  and  $\pm 5.6\%$ . Slight deviations from the Trevan dose-mortality characteristic and the significance of body-wt. and other factors in the assay are discussed.

F. O. H.

**Distribution, elimination, and accumulation of strophanthidin and the activity of its esters.** L. LENDLE (Arch. exp. Path. Pharm., 1936, 182, 72—86).—When tested on frogs, the esters (acetate, isovalerate, phenylpropionate, etc.) are less active than strophanthidin (I) and  $\frac{1}{2}$ — $\frac{1}{3}$  as active as *k*-strophanthin (II), whilst with the isolated frog's heart, the activities of the esters approx. equal that of (II). Comparative data for the toxicities, rate of elimination, distribution in cardiac and peripheral tissues, and cumulative action indicate no significant basic differences in mode of action between (I) and (II).

F. O. H.

**Effects of colchicine and related substances on cell division.** A. M. BRUES and A. COHEN (Biochem. J., 1936, 30, 1363—1368).—Mitosis in the regenerating liver of rats (after partial hepatectomy) is arrested by subcutaneous injection of colchicine (optimal dose 1.0—2.0 mg. per kg.), the effect occurring only within certain limits of dosage. Octahydro-colchicine, *N*-acetylcolchinal and its Me ether, colchinal Me ether hydrochloride, and the corresponding carbinol act similarly but considerably higher doses of them are required. Di- and tri-methyl-colchicinic acid are without effect in sub-lethal or lethal doses.

W. McC.

**Vagus[-stimulating] substances.** W. STRAUB and J. SCHOLZ (Arch. exp. Path. Pharm., 1936, 182, 331—339).—The use of a double cannula connected to two heart preps. in demonstrating the humoral transference of vagal action indicates that the esterase-inhibitory action (a controlling factor in the stimulation due to substances of the choline ester type) of prostigmine (I) is > that of eserine; the bearing of the constitution of these two drugs on this difference is discussed. HCN resembles (I) in its inhibition of esterase.

F. O. H.

**Influence of certain salts on morphine toxicity and narcosis in mice and rats.** J. M. ORT and W. G. CHRISTIANSEN (J. Amer. Pharm. Assoc., 1936, 25, 593—597).—The characteristic action of morphine is not significantly altered by simultaneous injection of aq.  $\text{NaH}_2\text{PO}_4$ , NaCNS, or NaCl; the results do not support Bancroft's theory of anaesthesia (A., 1931, 1932).

F. O. H.

**Prolongation of the local anaesthetic action of morphine-cocaine by calcium.** G. MATSCHULAN and C. AMSLER (Arch. exp. Path. Pharm., 1936, 182, 87—90).—Pre-injection of guinea-pigs with Ca gluconate prolongs the local anaesthesia following injection of cocaine-morphine mixtures. The mechanism of the phenomenon is discussed.

F. O. H.

**Relations between chemical constitution, pharmacological action, and therapeutic uses of the harmine group of alkaloids.** T. A. GUNN (Arch. int. Pharm. Ther., 1935, 50, 379—396; Chem. Zentr., 1935, ii, 3540).—The qual. action of harmine (I) is not changed by reduction to the  $\text{H}_2$ - or  $\text{H}_4$ -derivative. Introduction of Me or OMe has little effect. Substitution of OMe by phenolic OH modifies the convulsive action and decreases the effect on protozoa and to a smaller extent on mammals. Substitution of Me by Et etc. produces no fundamental change in the action. Ethylharmol is as toxic as (I) to protozoa: nonylharmol has a slower effect. The dilating action is more marked in the higher esters (highest in amyl compound).

A. G. P.

**Relation between pharmacological action and chemical constitution in the nicotine group.**—See this vol., 1276.

**Oxidation-reduction phenomena and functional activity of nervous tissue.** M. MITOLO (Atti R. Accad. Lincei, 1936, [vi], 23, 453—458).—Hyperexcitability (induced by strychnine or PhOH) of the reflex processes in toads and rats increases the

power of the central nervous tissue to reduce 2:6-dichlorophenol-indophenol. F. O. H.

**Strychnine. VI. Variation in physiological action.** J. C. WARD, J. C. MUNCH, and F. E. GARLOUGH (J. Amer. Pharm. Assoc., 1936, 25, 590—593).—Commercial preps. of "chemically-pure" strychnine show marked differences in toxicity which could not be correlated with variations in chemical or physical properties and are not changed by recrystallisation. F. O. H.

**Action of poisons on the isolated heart-muscle strip of frog. II. Alkaloids and their parent substances.** K. MEZEY and H. STAUB (Arch. exp. Path. Pharm., 1936, 182, 183—204).—The min. effective concn., type of action, reversibility (*i.e.*, return of sensitivity on washing with Ringer's solution), and mutual antagonism and synergism of 35 alkaloids and of  $C_5H_5N$ , piperidine, pyrrole, quinoline, and indole were investigated in rhythmically-stimulated frog's heart-strip preps. F. O. H.

**Relationship between diffusion of alkaloids through blood-vessels and their ultrafilterability through artificial membranes.** M. VOGT (Arch. exp. Path. Pharm., 1936, 182, 112—117).—Some alkaloids, *e.g.*, atropine and scopolamine, readily diffuse from aq. NaCl through Cellophane membranes which to others, *e.g.*, quinine and bulbocapnine, are only slightly permeable; the presence of serum diminishes the diffusibility of both groups. The bearing of the data on processes of absorption and permeation in the organism is discussed. F. O. H.

**Effect of veratrine and atropine on the tonus of skeletal muscle.** M. LAPORTA (Arch. Sci. biol., 1933, 19, 249—265; Chem. Zentr., 1935, ii, 3673).

A. G. P.

**Effect of adrenaline, atropine, and ergotamine on the excitability of the irido-dilatory sympathetic system.** D. BOLSI and F. VISINTINI (Boll. Soc. ital. Biol. sperim., 1934, 9, 253—255).

R. N. C.

**Halogen analogues of adrenaline and ephedrine. III.**—See this vol., 1254.

**Acetylcholine and eserine.** F. ZINNITZ (Arch. exp. Path. Pharm., 1936, 182, 340—347).—The action of acetylcholine (I) on blood-pressure etc. is prolonged but not intensified by prior injection of eserine (II); the latent period is also increased. The effect, which is reversible, is due to the esterase-inhibitory action of (II) diminishing the rate of hydrolysis of (I).

F. O. H.

**Effect of sympathomimetic and parasympathomimetic substances on the chemical processes producing the energy of muscular contraction. I. Effect of adrenaline, pilocarpine, and potassium on the formation of lactic acid and decomposition of phosphagen.** D. NACHMANSOHN, J. WAIZER, and R. LIPMANN (Bull. Soc. Chim. biol., 1936, 18, 1207—1231).—Adrenaline in concns. of  $1-2 \times 10^{-4}\%$  at  $pH$  7.2 immediately increases the lactic acid (I) formation of resting anaerobic muscle (frog); phosphagen (II) resynthesis is induced only after some time and is independent of the [P] in the Ringer's solution. In fatigued muscle,

4 P

however, resynthesis of (II) runs parallel with formation of (I); poisoning the muscle with  $CH_3I-CO_2H$  prevents this resynthesis. These effects are not observed with guinea-pig's muscle. At  $pH$  6.4, (I) formation is less rapid and the (II) changes depend on the [P] in the Ringer's solution. At  $pH$  8.0, resynthesis and decomp. of (II) are retarded. Pilocarpine and  $K^+$  accelerate both formation of (I) and decomp. of (II). H. D.

**Effect of certain substances on phosphate compounds in the liver of dogs.** E. FLOCK, J. L. BOLLMAN, and F. C. MANN (J. Biol. Chem., 1936, 115, 201—206).—Injection of adrenaline produced no change in the acid-sol.  $PO_4'''$ , whilst administration of thyroxine, phloridzin, and  $CCl_4$  over intervals for a few days did not produce extremely fatty livers or low vals. for  $PO_4'''$  unless used with a fatty diet. In these dogs, as well as in depancreatised dogs deprived of insulin, only when the liver became extremely fatty were the vals. for  $PO_4'''$  reduced to < normal. J. N. A.

**Toxicity of fish-liver oil and the antitoxic effect of yeast. II. Antitoxic effect of alcoholic extract of yeast.** I. YAMAMOTO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 590—594; cf. A., 1935, 233).—The food consumption and growth of rats on a diet containing 15% of cod-liver oil were increased by the addition of 50% aq. EtOH extract of yeast, but not quite so markedly as by that of yeast itself.

W. O. K.

**Comparison of toxicity and general effects of natural, *dl*-, and *l*-camphor on the rat.** R. HAZARD and R. LARDÉ (J. Pharm. Chim., 1936, [viii], 24, 149—154; cf. A., 1935, 526).—When injected intraperitoneally (in oil) into white rats, the order of toxicity and lethal action is  $l > dl > d$ . J. N. A.

**Correlation of toxicity with optical activity of *Derris* derivatives.** R. S. CAHN (J.S.C.I., 1936, 55, 259—260r).—Since *dl*-dihydrodeguelin (I) is less toxic to mosquito larvae than one tenth of its wt. of the *l*-form (II) (Fink and Haller, J. Econ. Entom., 1936, 29, 595), either the biological results are very inaccurate (possibly owing to different rates of agglomeration of suspensions of the two forms), or (I) and (II) are *cis-trans* ring isomerides. Such isomerisation may be caused by alkali. The connexion (*cf. loc. cit.*) of differences in toxicity with optical isomerism and of the toxicity of the non-rotenone portion of *Derris* extract with the presence of (II) therein is thus not proved. R. S. C.

(A) Spectrographic determination of blood-lead; its value in diagnosis of lead poisoning. (B) Plasma-cell partition of blood-lead in clinical lead poisoning. H. BLUMBERG and T. R. MCN. SCOTT (Bull. Johns Hopkins Hosp., 1935, 56, 276—293, 311—316).—(A) Blood is ashed and burnt on graphite electrodes. Non-pathological blood shows 0.005—0.1 mg. and pathological blood >0.2 mg. of Pb per 100 c.c.

(B) In cases of blood poisoning approx. 90% of the blood-Pb was in the cells or the clot. The cell fraction contained <50% of the non-pathological Pb. Isotonic NaCl does not remove Pb from cells separated from serum. CH. ABS. (p)

Toad poisons.—See this vol., 1252.

Snake poisons. F. MICHEEL (Chem.-Ztg., 1936, 60, 753—755).—A review.

Nature and action of enzymes. H. ALBERS (Angew. Chem., 1936, 49, 448—455).—A review.  
E. W. W.

Application of the chain theory of chemical change to certain enzyme reactions. E. A. MOELWYN-HUGHES (Acta Physicochim. U.R.S.S., 1935, 3, 593—612).—A consideration of the characteristics of chain reactions leads to the view that among enzyme reactions only enzymic oxidation can be examined in the light of the chain theory. Simple mathematical treatment leads to the conclusion that the Michaelis const. is inversely  $\propto$  the average length of the chain. The theory is applied to the oxidation of luciferin, catalysed by luciferase, and purine bases, catalysed by xanthine-oxidase.  
C. R. H.

Nature of autolysis. H. HAEHN (Woch. Brau., 1936, 53, 259—263).—A review.  
I. A. P.

Origin and significance of blood-serum enzymes. L. A. CRANDALL, jun. (Amer. J. Digest. Dis. Nutrition, 1935, 2, 230—235).—A review.

CH. ABS. (p)  
Biochemistry of *Bombyx mori*, L. XVI. K. YAMAFUJI (Biochem. Z., 1936, 286, 225—228).—Curves are given showing changes in the catalase (I), peroxidase, invertase, tyrosinase, maltase, amylase, lipase, and protease activity and in the mitogenetic effect of the blood during the various stages of metamorphosis. In both cases a close relationship exists between (I) activity and mitogenetic effect.  
P. W. C.

Enzymes of trypanosomes. B. J. KRIJGSMAN (Natuurwetensch. Tijds., 1936, 18, 237—241).—*T. evansi* contains cathepsin, carboxy- and aminopolypeptidase, and dipeptidase but no lipase, carbohydrazase, or protease. It lives entirely on simple substances in the blood-stream and needs enzymes only for the synthesis of protoplasm. Toxins produced by this trypanosome are amines produced by the decarboxylation of  $\text{NH}_2$ -acids.  
S. C.

Digestive enzymes of *Anemonia sulcata*. M. SAVIANO (Boll. Soc. ital. Biol. sperim., 1936, 11, 145—146).—The endoderm contains tributyrase and trypsin but not lipase, amylase, or pepsin.  
F. O. H.

Determination of enzyme concentration in duodenal fluids. C. W. LUEDERS (Amer. J. Digest. Dis. Nutrition, 1935, 2, 224—229).—Methods for trypsin, lipase, and amylase are described.

CH. ABS. (p)  
Isolation and properties of the indophenol-oxidase from yeast cells and heart muscle. S. YAMAGUCHI, H. TAMIYA, and Y. OGURA (Acta Phytochim., 1936, 9, 103—106).—Indophenol-oxidase, isolated from yeast cells or heart muscle and free from cytochrome and haemochromogen, is indifferent towards CO; its action is greatly restricted by  $\text{CN}^-$ .  
H. W.

Haematin and peroxidase of fig sap. J. B. SUMNER and S. F. HOWELL (Enzymologia, 1936, 1, 133—134).—Fig. sap is a rich source of peroxidase,

preps. of which contain no free haematin, but reduced haematin may be present.  
E. D. Y.

The Schardinger enzyme and xanthine-oxidase of milk. D. MICHLIN, A. JEMELJANOV, and M. SOLOVJEVA (Enzymologia, 1936, 1, 151—155).—The two enzymes vary similarly during lactation and appear to be identical.  
E. D. Y.

Diffusion of the dehydrogenase of higher fatty acids in various organs. F. P. MAZZA (Boll. Soc. ital. Biol. sperim., 1934, 9, 298—299; Chem. Zentr., 1935, ii, 3396; cf. A., 1935, 782).—Kidney sections placed in Ringer- $\text{PO}_4^{'''}$  buffer ( $p_{\text{H}}$  7.4) until the  $\text{O}_2$  consumption has decreased considerably show a marked increase in  $\text{O}_2$  consumption on addition of Na palmitate. There is no corresponding production of  $\text{CO}_2$ .  
A. G. P.

Amino-acid dehydrogenase. II. Activator of proline dehydrogenase. N. B. DAS (Biochem. J., 1936, 30, 1617—1621).—An activator (cf. this vol., 894) of proline dehydrogenase (I) of pig's kidney is present in baker's yeast and can be adsorbed on acid clay, frankonit, and animal C from faintly acid solution, but not by kaolin or  $\text{Al}(\text{OH})_3$   $\text{C}_\gamma$  (Willstatter), is pptd. by  $\text{AgNO}_3$  and  $\text{Hg}(\text{OAc})_2$ , is not inactivated by  $\text{HNO}_2$ ,  $\text{H}_2\text{O}_2$ , or aeration, is not extracted by  $\text{Et}_2\text{O}$  from alkaline solution, and is pptd. by  $\text{EtOH}$ . Lactoflavin is incapable of activating (I).  
P. W. C.

Aminodehydrogenases of the animal body. B. KISCH (Enzymologia, 1936, 1, 97—106).—Preps. of  $\alpha$ -aminodehydrogenases from liver and kidney of various animals contain three different enzymes. A relationship exists between their activity (optimum  $p_{\text{H}}$  7.0—7.6) and the C-chain length of the substrate. Quinone models for two of the types are suggested. Liver preps. are less active than kidney preps.  
E. D. Y.

Effect of glutathione and other substances on the inactivation of catalases. G. W. MARKS (J. Biol. Chem., 1936, 115, 299—314).—The inactivation of mussel-catalase (I) is a unimol. reaction, and of a large no. of substances studied,  $\text{MeOH}$ ,  $\text{EtOH}$ , and  $\text{KCN}$  decrease, and ascorbic acid (II) and glutathione (III) increase,  $k$ . Dialysis of mussel-(I) preps. to remove (II) and (III), however, has no effect on their stability. The p.d. at a Pt electrode decreases linearly with time although this change is not directly correlated with the course of inactivation. Ox kidney-(I) is made unstable by (III) and this condition is similar to unstable mussel-(I).  
H. D.

Catalase activation in living cells. K. YAMAFUJI (Enzymologia, 1936, 1, 120—124).—Ultra-violet irradiation of *Saccharomyces ellipsoideus*, *S. rosa*, and, notably, *S. colliculosa* increases the catalase activity (up to 25 times). The effect is less evident in presence of glucose or koji-agar.  
E. D. Y.

Influence of antiseptics on amylolytic actions. M. VAN HAUWAERT (Natuurwetensch. Tijds., 1936, 18, 187—190).—Small amounts of  $\text{C}_6\text{H}_6$ ,  $\text{PhMe}$ , xylene,  $\text{CHCl}_3$ ,  $\text{CHBr}_3$ , or  $\text{COMe}_2$  have practically no effect on the saccharification of starch by diastase but  $\text{CHI}_3$  reduces the rate considerably.  
S. C.

**Purification of koji amylase by precipitation.** N. TAKETOMI and S. TAKEDA (Bull. Waseda Appl. Chem. Soc., 1935, 25, 11—15).—Aq. amylase (I) concentrates can usually be pptd. by addition of EtOH (2 vols.) or COMe<sub>2</sub> (0.55 vol.). Treatment with suitable proportions of EtOH-COMe<sub>2</sub> (1 : 2 vol.) dissolves (I) but ppts. invertase and protein. Further impurities in (I) may be pptd. by Pb(OAc)<sub>2</sub> or BaCl<sub>2</sub>.  
CH. ABS. (p)

**Amylase activity as a racial characteristic in silkworms.** K. YAMAFUJI, I. HIRAIWA, and S. GOTO (Biochem. Z., 1936, 286, 229—231).—The amylase content of the digestive juices and blood of European strains of *Bombyx mori* is extremely small compared with that of Japanese and Chinese strains; the former also show a smaller survival rate when exposed to unfavourable conditions of growth.

P. W. C.

**Blood-amylase and body-strength of some strains of silkworms.** K. YAMAFUJI and S. GOTO (Bull. Agric. Chem. Soc. Japan, 1936, 12, 75—77).—With three new strains during the fifth larval stage the amylase content of the blood increased daily, that in females being generally > that in males. The resistance of the worms to conditions of unfavourable growth varied considerably, that of the females being always slightly < that of the males.  
J. N. A.

**Rates of digestion of starches and glycogen and their bearing on chemical constitution. I. Action of amylases on starches and glycogen.** G. E. GLOCK (Biochem. J., 1936, 30, 1386—1396).—Determinations of achromic point, residual polysaccharide, total reducing power, and reducing power after pptn. of dextrans indicate the course of digestion of potato-, wheat-, maize-, and rice-starch and glycogen (I) by pancreatic amylase, and of wheat-starch and (I) by salivary amylase and malt-diastase. The rates of degradation are different for the different starches, each of which, however, is hydrolysed more rapidly than (I). Glucose is not produced except with high concns. of amylase and the reducing sugar which constitutes the end-product is not maltose or isomaltose.  
W. McC.

**Enzymic power of dead human livers and kidneys.** V. GETREUER and G. OBERSOHN (Z. ges. exp. Med., 1935, 96, 51—59; Chem. Zentr., 1935, ii, 2542).—The kidneys exhibit a diastatic action which oscillates in potency; it is uninfluenced by disease, and is regularly distributed between the cortex and the medulla. Glycogen is high in the kidneys in some cases of diabetes mellitus. The secondary enzymic power is uninfluenced by diabetes or previous treatment with insulin (I). The liver enzymes are less potent than the kidney enzymes normally, but are more potent in Basedow's disease and necrosis of the pancreatic fat tissue; in diabetes they are slightly more potent or of equal potency, and are inhibited by (I).  
R. N. C.

**Comparison of methods for determining diastase in duodenal fluid.** C. R. SCHMIDT, H. GREENGARD, and A. C. IVY (Amer. J. Digest. Dis. Nutrition, 1934, 1, 618—627).—Willstätter's hypiodite titration is best suited for clinical analysis. Amylolytic activity (duodenal drainage fluid) is

optimal at  $p_H$  6.8. Maltase in the fluid is insufficient to cause variation of results in a starch substrate at  $p_H$  6.8. MgSO<sub>4</sub> (up to 5%) and bile do not affect amylolytic activity as determined by a modified Willstätter procedure.  
CH. ABS. (p)

**Invertase. III. Elution from adsorbents.** N. TAKETOMI (J. Soc. Chem. Ind. Japan, 1936, 39, 206B; cf. this vol., 243).—Invertase (I) adsorbed on activated C is eluted partly by aq. NH<sub>3</sub> at  $p_H$  9.2; the eluate contains neither proteins nor reducing sugars. From Al(OH)<sub>3</sub> or activated clay (I) is readily eluted by 0.2% aq. NH<sub>3</sub> or (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> at  $p_H$  7.0—7.3; if adsorption on clay is carried out above 30°, elution is difficult.  
J. L. D.

**Influence of the aglucone on the rate of hydrolysis of  $\beta$ -glucosides by emulsin.** S. VEIBEL and F. ERIKSEN (Compt. rend., 1936, 203, 390—392).—The rate of hydrolysis of  $\beta$ -glucosides by emulsin is in the order Me < Et < Pr <sup>$\alpha$</sup>  > Pr <sup>$\beta$</sup>  < Bu > trimethylcarbinol < *d*-methylbutylcarbinol. The arrangement of the groups in the mol. is of importance. The introduction of two Me increases the rate of hydrolysis, but the presence of a third Me almost stops hydrolysis. *d*-Methylbutylcarbinol- $\beta$ -*d*-glucoside is hydrolysed approx. 15,000 times as quickly as trimethylcarbinol- $\beta$ -*d*-glucoside.  
J. N. A.

**Baicalinase, an enzyme which hydrolyses flavone glycuronides. III.** T. MIWA (Acta Phytochim., 1936, 9, 89—102; cf. A., 1932, 650).—Although baicalin is unaffected by technical emulsin (*loc. cit.*), it (and scutellarin) are hydrolysed by freshly-prepared emulsin from the seeds of *Prunus armeniaca*, var. *Ansu*, Maxim, or from bitter almonds. The probability that the hydrolysis of flavone glycuronides and  $\beta$ -glucosides is effected by specifically different  $\beta$ -glucosidases of emulsin is strengthened by the following observations. The ratio of the activity of glycuronide to glucoside fission varies with the purification of the enzyme. These actions vary independently when the enzyme is treated with adsorbents. Various harmful influences (increased [H<sup>+</sup>]; increased temp.; ultra-violet irradiation) influence the actions in differing degrees.  
H. W.

**Canavanine. V. Natural occurrence of  $\gamma$ -ethylidenecanaline, the condensation product between canaline and acetaldehyde, during the enzymic hydrolysis of canavanine.** M. KITAGAWA, K. SAWADA, and Y. HOSOKI (J. Agric. Chem. Soc. Japan, 1935, 11, 539—544; cf. A., 1934, 993).—Canavanine, with a pig-liver extract at 37°, affords canaline and  $\gamma$ -ethylidenecanaline, C<sub>6</sub>H<sub>12</sub>O<sub>3</sub>N<sub>2</sub>, m.p. 233—234°,  $[\alpha]_D^{25}$  -8.96° in H<sub>2</sub>O (also from canaline and MeCHO), hydrogenated to a  $\gamma$ -hydroxy- $\alpha$ -amino acid, C<sub>4</sub>H<sub>9</sub>O<sub>3</sub>N, m.p. 204°.  
CH. ABS. (r)

**Enzymic synthesis of alkylglucosides.** S. VEIBEL (Enzymologia, 1936, 1, 124—132).—The synthetic activity of emulsin is shown for 8 alcohols by the optical method. Equilibrium consts. and heats of reaction are given.  
E. D. Y.

**Hepatic origin of serum-lipase.** N. FIESSINGER and A. GAJDOS (Enzymologia, 1936, 1, 145—150).—Serum-lipase is decreased in liver disease, increased

by parenteral administration of liver-lipase, and unchanged after pancreatectomy. E. D. Y.

**Method of enzymic ester synthesis.** E. A. SYM (Enzymologia, 1936, 1, 156—160).—Na gallate and bile salts catalyse the esterification of oleic acid + cholesterol,  $\text{PrCO}_2\text{H}$  + cyclohexanol, etc. in  $\text{C}_6\text{H}_6$  or  $\text{CCl}_4\text{--H}_2\text{O}$ . E. D. Y.

**Isolation from beef pancreas of crystalline trypsinogen, trypsin, a trypsin inhibitor, and an inhibitor-trypsin compound.** M. KUNITZ and J. H. NORTHROP (J. Gen. Physiol., 1936, 19, 991—1007; cf. A., 1935, 785).—Detailed methods for the prep. of trypsinogen, trypsin (I), a substance which inhibits (I), and an inhibitor-(I) compound are given. The inhibitor appears to be a polypeptide, mol. wt. 6000, low in C and N compared with proteins. A solution of (I)+inhibitor is inactive in the  $p_{\text{H}}$  range 7.0—3.0, but becomes active at  $p_{\text{H}}$  1.0; this action is reversible and takes about  $\frac{1}{2}$  hr. to reach completion. The inhibitor also inhibits chymotrypsin, but less markedly. F. A. A.

**Proteolytic enzymes in the uterine fluid of selachians.** M. SAVIANO (Boll. Soc. ital. Biol. sperim., 1936, 11, 146—148).—The uterine fluid of *Torpedo ocellata* and *T. marmorata* contains a peptic type whilst that of *Mustelus laevis* contains a tryptic type of protease. F. O. H.

**Activity of cathepsin and dipeptidases of the tissues of regenerating and normally-developing liver of birds.** V. N. ORECHOVITSCH (Biochem. Z., 1936, 286, 248—253).—Cathepsin (I) and dipeptidase (II) activities of normal and regenerating liver of hens and pigeons and of developing embryo chicks are tabulated. With hens, both tissues have the same (I) and (II) activity. With chick embryos, the liver-(I) activity is only 47% on the 13th day but by the 15th day reaches the adult val. whereas the (II) activity shows a max. on the 15th day. In pigeons, the liver-(II) activity is much more const. than in hens and increases considerably with regenerating tissue. P. W. C.

**Error due to blood-arginase in the urease method of determining blood-urea.** A. B. ANDERSON and S. L. TOMPSETT (Biochem. J., 1936, 30, 1572—1576).—The urea (I) content of human blood determined by incubation with a conc. solution of urease (II) (cryst. or from soya or Jack bean) is too high because (II) is attacked by arginase (III) in the corpuscles. (III) is inactivated by incubation at 37—50° for 10 min. after addition of acid and is activated by  $\text{Co}^{++}$ , which produces an increase of up to 100% in the apparent (I) content. When conc. (II) solutions are incubated with liver-(III) a similar production of  $\text{NH}_3$  occurs. For accurate determination of blood-(I) plasma should be used. W. McC.

**Structure of urea with reference to its deamination and synthesis by urease.** W. R. FEARON (Biochem. J., 1936, 30, 1652—1660).—Studies of zymolysis of urea (I) in presence of trapping agents, e.g., Ba, Ca, and Pb salts, semicarbazide, etc., and of the synthesis of (I) by urease (II) from  $\text{NH}_4$  carbonate-carbamate indicate that in the (I)-(II)

system, (I) reacts in the unsymmetrical or *iso*-form with the formation of  $\text{NH}_3$  and  $\text{NH}_2\cdot\text{CO}_2\text{H}$ . The high dielectric const. of (I) supports the suggestion that (I) is largely present in the zwitterionic form  $^+\text{NH}_3\cdot\text{C}(\text{NH})\cdot\text{O}^-$ . P. W. C.

**Distribution of urease in dog's stomach.** K. LINDERSTRÖM-LANG and A. S. ØHLSEN (Enzymologia, 1936, 1, 92—95).—Urease is situated in the surface layers of the mucosa of the fundus and pylorus in cells which stain with mucicarmine. The gastric mucosa of pigs is inactive. E. D. Y.

**Enzymic amylolysis. VI. Colour produced in dephosphorylated potato-starch by iodine.** M. SAMEC, E. WALDSCHMIDT-LEITZ, and K. MAYER (Z. physiol. Chem., 1936, 242, 165—168; cf. this vol., 111).—Potato-starch dephosphorylated with amylophosphatase from barley and kidney-phosphatase does not differ appreciably from the untreated starch as regards the colour produced with I. W. McC.

**Effect of  $\alpha$ -amino-acids and magnesium on the activity of kidney- and intestinal phosphatases.** O. BODANSKY (J. Biol. Chem., 1936, 115, 101—110).— $\alpha\text{-NH}_2$ -acids prevent inactivation of the phosphatases whilst Mg increases the initial velocity of reaction. The velocity, at optimal concn. of glycine and Mg,  $\propto$  the concn. of the enzyme. Prolonged dialysis inactivates the enzymes. H. G. R.

**Phosphatases. V. Influence of buffer composition on the course of the activity- $p_{\text{H}}$  curves of phosphoesterases. VI. Presence in animal organs of a second phosphoesterase active in acid solution.** E. BAMANN and W. SALZER (Biochem. Z., 1936, 286, 143—146, 147—159; cf. A., 1935, 402).—V. The form of the  $p_{\text{H}}$ -activity curves for the action of spleen-phosphoesterase, extracted with dil.  $\text{AcOH}$ , on Na  $\beta$ -glycerophosphate varies considerably with varying concn. of citrate ions, only one clearly defined max. being obtained with const. citrate ion concn. and two max. with Sørensen's buffer mixture.

VI. The differences in the  $p_{\text{H}}$ -activity curves for animal phosphatases according to the method of prep., substrate, etc. are due partly to the buffer effect but chiefly to the fact that two esterases having optima at  $p_{\text{H}}$  4 and 5.5, respectively, are present to differing extents. Urine contains only the enzyme of optimum  $p_{\text{H}}$  5.5. The amount of the enzyme of optimum  $p_{\text{H}}$  4 can be decreased by adsorption methods and it can be selectively destroyed by the action of alkali. The enzyme of optimum  $p_{\text{H}}$  5.5 is not identical with that of the red cells since the organ-enzyme attacks preferentially  $\beta$ -glycerophosphate and is not activated by  $\text{Mg}^{++}$  whilst the red cell-enzyme has an optimum  $p_{\text{H}}$  6.4, reacts preferentially with  $\alpha$ -glycerophosphate, and is activated by  $\text{Mg}^{++}$ . The animal organism thus possesses four different isodynamic non-sp. phosphatases, one of optimum  $p_{\text{H}}$  9. No evidence could be obtained for the existence of an enzyme of optimum  $p_{\text{H}}$  2.9—3.2. P. W. C.

**Synthesis of phospho-*d*-tartaric acid and its decomposition by phosphatase.** C. NEUBERG and W. SCHUCHARDT (Enzymologia, 1936, 1, 39—47).—

$\text{POCl}_3$  with *d*-tartaric acid in quinoline affords the acid, which is hydrolysed by taka-phosphatase ( $p_{\text{H}}$  optima at 4.0 and 5.7). E. D. Y.

**Variations in the phosphomonoesterase content of milk in relation to the progress of lactation.** S. J. FOLLEY and H. D. KAY (*Enzymologia*, 1936, 1, 48—54).—The concn. of milk-phosphatase increases during lactation whilst the total daily phosphatase content is max. 180 days after parturition. Serum-phosphatase shows no parallel changes.

E. D. Y.

**Inactivation of milk-phosphatase.** S. HERSCHDORFER (*Enzymologia*, 1936, 1, 96).—Slow cooling after heat-inactivation permits partial regeneration of the enzyme.

E. D. Y.

**Phosphatase of bones.** A. ROSSI (*Boll. Soc. ital. Biol. sperim.*, 1933, 8, 714—719; *Chem. Zentr.*, 1935, ii, 3397).—A prep. of phosphatase (I) from dog bones showed optimum activity at  $p_{\text{H}}$  7.0—8.55, decreasing rapidly at  $>9.5$ .  $\text{Mg}^{++}$ ,  $\text{Ca}^{++}$ , and  $\text{F}^-$  decreased the action of (I), which did not attack lecithin.

A. G. P.

**Phosphatase in subcutaneous tissue of dogs.** F. CEDRANGOLO (*Bol. Soc. ital. Biol. sperim.*, 1936, 11, 140—141).—An enzyme is present hydrolysing glycerophosphate, activated by  $\text{Mg}^{++}$ , and inhibited by  $\text{Na}_3\text{AsO}_4$ ,  $\text{CH}_2\text{Br}\cdot\text{CO}_2\text{H}$ , or  $\text{NaF}$ .

F. O. H.

**Effect of nucleophosphatase on thymus nucleohistone.** G. SCHMIDT (*Enzymologia*, 1936, 1, 135—141).—Hydrolysis is markedly increased after digestion of the natural nucleic acid with crude pancreas extract but not with pure trypsin.

E. D. Y.

**Heterophosphatase.** E. BAUER (*Z. physiol. Chem.*, 1936, 242, 29—39).—The heterophosphatase (I) of bottom yeast is not identical with Albers' phosphatase from top yeast,  $\alpha$ -glycerophosphatase (II), or pyrophosphatase although (I) possibly acts together with (II). Activation of (I) with  $\text{Mg}^{++}$  is optimal with  $[\text{Mg}^{++}]$  0.01—0.001*M*. When fructose (III) is the P acceptor, the activity of (I) is very low at  $p_{\text{H}}$  4.3—7.0. (I) produces mono-esters with glucose and (III). (I) appears not to esterify galactose and ribose and to esterify mannose more easily than glucose.

W. McC.

**Effect of autolysis on phosphate compounds in the liver of dogs.** E. FLOCK (*J. Biol. Chem.*, 1936, 115, 207—210).—Autolysis of the liver-tissue at room temp. for 15 min. hydrolyses labile nucleotide with production of inorg.  $\text{PO}_4'''$ . During 4 hr. autolysis there is a further but slower increase in inorg.  $\text{PO}_4'''$  due to breakdown of more stable acid-sol. esters. Occasionally there is an increase due to breakdown of the residual or nucleic acid fraction. The phospholipids are unchanged.

J. N. A.

**Enzymic hydrolysis of lactoflavinphosphoric acids.** H. RUDY (*Z. physiol. Chem.*, 1936, 242, 198—200).—Lactoflavinphosphoric acid (I), prepared by vigorous action of  $\text{POCl}_3$  on lactoflavin (II), in addition to lacking growth-promoting properties is much more slowly hydrolysed by glycerol extract of rat's intestine than are the acids from heart and yeast and the acid (III) obtained from (I) by gentle action of  $\text{POCl}_3$ , although the final extent of hydrolysis is the

same in all cases. The acids from heart and yeast and (III) are hydrolysed at the same rate.  $\alpha$ -Glycerophosphatase (IV) attacks these three equally rapidly but (I) much more slowly.  $\beta$ -Glycerophosphatase acts does (IV). Cytoflavin (V) from heart is identical with the acid from yeast. Interaction of (II) with  $\text{POCl}_3$  produces phosphoric esters not identical with (V).

W. McC.

**Aldolase.**—See this vol., 1232.

**Enzymes of lactic acid fermentation and glycogenolysis.** R. LOHMANN (*Arch. exp. Path. Pharm.*, 1936, 182, 239—242).—Muscle-pulp from animals showing muscle-glycogenolysis [indicated by creatinuria (Brentano, A., 1932, 83)] has a lactic acid (I) production (normal or increased by caffeine) similar in velocity and extent to that of muscle from normal animals. Hence the enzymes producing (I) are not influenced by depletion of muscle-glycogen.

F. O. H.

**Separation of glyoxalase activity and glycolytic activity by means of radium radiation.** H. G. CRABTREE (*Biochem. J.*, 1936, 30, 1622—1629).—The anaerobic glyoxalase (I) activity of normal and tumour rat tissue is measured. All tissues including pancreas showed considerable activity, particularly tumour tissue, with which the activity was of the same order as the anaerobic glycolysis. Ra radiation applied at low temp. to these tissues suppressed the anaerobic glycolysis almost completely whilst (I) activity was unaffected. Total suppression with rat retina (the most sensitive tissue) was effected in 1—2 hr.

P. W. C.

**Activation and inhibition of zymoheaxase.** E. BAUER (*Z. physiol. Chem.*, 1936, 242, 15—18; cf. this vol., 894).—The inactivation of zymoheaxase (I) solutions on diluting is not due to destruction of (I) but to heavy metals, since elimination of metals and activation (at first  $\propto$  amount of activator) follow addition of KCN,  $\text{H}_2\text{S}$ , cysteine, glutathione, and activator from muscle. Inactivation is produced by  $\text{Cu}^{++}$  (irreversible),  $\text{Ag}^+$ ,  $\text{Hg}^{++}$ , and  $\text{Zn}^{++}$ . Activation is not (or at least not exclusively) due to production of a cyanohydrin or similar compound.

W. McC.

**Alcoholic fermentation in the intact enzyme system of the yeast cell and in the disorganised zymase system.** I. R. NILSSON and F. ALM (*Biochem. Z.*, 1936, 286, 254—278).—The influence of various  $[\text{PO}_4''']$  and temp. on the course of the fermentation curve is investigated using fresh and dried yeast. Without  $\text{PO}_4'''$  addition the course is approx. the same for both yeasts, but with dried yeast or maceration juice on adding  $\text{PO}_4'''$  a deflexion in the curve which is independent of sugar concn. or  $[\text{PO}_4''']$  occurs when 50% of the added sugar has been fermented to  $\text{CO}_2$ . Similar results are obtained with sucrose, the deflexion being more clearly defined at  $40^\circ$  than at  $30^\circ$  and corresponding with the max. of phosphorylation although 28% of the added  $\text{PO}_4'''$  is still unesterified. Hexose diphosphate is probably not a normal intermediate product during fermentation with the intact cell, the velocity of its fermentation being small. Schemes are given for the reactions occurring with varying amounts of  $\text{PO}_4'''$ .

P. W. C.

**Phosphorylation in living yeast.** M. G. MACFARLANE (Biochem. J., 1936, 30, 1369—1379).—During the fermentation of sugar the acid-sol.  $\text{PO}_4'''$  of fresh brewery yeast first decreases, then remains fairly const., and finally regains the original level when fermentation ceases. The compound produced by the disappearing  $\text{PO}_4'''$  is possibly acid-insol. A method for the successive extraction of P compounds from fresh yeast is described. Aq.  $\text{CCl}_3\text{-CO}_2\text{H}$  extract of fresh yeast contains  $\text{PO}_3'$  but apparently not hexose mono- or di-phosphate. Approx. 30% of the total P of yeast is present as a complex containing Fe, a nucleic acid (I) (possibly ribonucleic), and  $\text{PO}_3'$ . The complex may be identical with Kossel's plasmic acid (A., 1893, i, 680). The  $\text{PO}_3'$  of the (I) fraction is converted into  $\text{PO}_4'''$  during the autofermentation of yeast in presence of PhMe.

W. McC.

**Influence of the substrate on the respiration of and fermentation by yeast cells.** W. LIBBRECHT (Natuurwetensch. Tijds., 1936, 18, 84).—Increase in the pressure of  $\text{O}_2$  inhibits the fermentation of glucose and  $\text{AcCO}_2\text{H}$ . With  $\text{AcOH}$ ,  $(\text{CH}_2\text{-CO}_2\text{H})_2$ , and  $\text{EtOH}$  there is a slight inhibitive action, whilst with lactic acid fermentation is increased. This inhibition is the greater, the more easily the substrate ferments under atm. pressure.

D. R. D.

**Alcoholic fermentation of various sugars.** G. AMADIO (Annali Chim. Appl., 1936, 26, 258—262).—Determinations of  $\text{EtOH}$ , glycerol, acidity, and  $\text{CO}_2$  formed by the action of *Saccharomyces cerevisiae*, Hansen, and of *S. ellipsoideus*, Hansen, indicate that glucose, fructose, galactose (I), sucrose, maltose, mannose, and raffinose (II) are readily fermented except that (I) is unattacked and (II) only to the extent of approx.  $\frac{1}{3}$  by *S. ellipsoideus*.

F. O. H.

**Phytochemical reduction of triketopentane.** C. NEUBERG and W. M. CAHILL (Enzymologia, 1936, 1, 142—144).—Yeast reduces  $\text{COAc}_2$  to *s*-dimethylglycerol.

E. D. Y.

**Nitrogen assimilation of yeast.** VII. Ability of yeast to assimilate amino-acids. N. NIELSEN (Compt. rend. Trav. Lab. Carlsberg, 1936, 21, No. 16, 395—425; cf. this vol., 1026).—N assimilation is determined by the decrease of N in solution, not by the growth of the yeast, as the latter does not necessarily depend on assimilation of N. Addition of a growth-promoting factor, e.g., beer wort, is essential. Of the 27  $\text{NH}_2$ -acids examined, 12 are completely assimilated and 8 are not assimilated. Partial assimilation is due, in *dl*-mixtures, to assimilation of one stereoisomeride only, and with *l*-tryptophan, *l*-histidine, and *d*-arginine to the assimilation of the  $\text{NH}_2\text{-N}$  only.

E. A. H. R.

**Relationship between the metabolism of yeast and lactic acid bacteria and the oxidation-reduction potential of the medium.** A. J. KLUYVER and J. C. HOOGERHEIDE (Enzymologia, 1936, 1, 1—21).— $E_h$  at  $p_H$  5.2 of suspensions of *Saccharomyces cerevisiae* depends on the nature of oxidation-reduction dye added. Nile-blue and chloraphin (0.001%) give characteristic  $E_h$  for yeast of  $-43$  mv. These dyes cause no marked change in anaerobic

glycolysis;  $E_h$  is const. and independent of dye concn. Vals. for other yeast strains vary from  $-27$  to  $-43$  mv. In aerobic glycolysis,  $E_h$  is a function of R.Q. and not  $Q_{O_2}$  (cf. A., 1934, 1138). 18 types of lactic acid bacteria give  $r_H$  vals. of 5—6 in milk cultures with universal reduction-oxidation mixture.

E. D. Y.

**Biological role of hydroxylamine.** IV. Utilisation of hydroxylamine salts by *Aspergillus niger*. V. Production of hydroxylamine by *A. niger* at the expense of nitrate- and ammonia-nitrogen. M. LEMOIGNE, P. MONGUILLON, and R. DESVEAUX (Bull. Soc. Chim. biol., 1936, 18, 1291—1296, 1297—1303; cf. this vol., 639).—IV.  $\text{NH}_2\text{OH}$  retards the growth of *A. niger* only in concns. of  $<0.1$ — $0.2\%$ . The mould grown in a medium of  $\text{NH}_4\text{NO}_3$  produces  $\text{NH}_2\text{OH}$  and even when the latter is the only source of N, synthesis of protein occurs with evolution of  $\text{NH}_3$ .

V. *A. niger* can form  $\text{NH}_2\text{OH}$  by oxidation of  $\text{NH}_3$  or reduction of  $\text{NO}_3'$ ; various theories concerning the role of  $\text{NH}_2\text{OH}$  in the synthesis of proteins are discussed.

H. D.

**Isolation and identification of *B. coli*.** G. MONTALDO (Boll. Soc. ital. Biol. sperim., 1936, 11, 181).—The characteristic appearance of colonies of *B. coli* grown in neutral or slightly alkaline 30% lactose-agar containing 0.005—0.01% of Congo-red is described.

F. O. H.

**Formation of alcohol from pentoses.**—See B., 1936, 758.

**Acetone-butanol fermentation.** IX. Isolation of organism. B. ROKUSHO (J. Agric. Chem. Soc. Japan, 1936, 12, 639—649).—The organism (isolated from corn and apparently a strain of *Clostridium acetobutylicum*) ferments many sugars and polysaccharides, but not Ca lactate, inulin, glycerol, isodulcitol, trehalose, or melibiose. From corn, rice, and millet it produces 10—11% of  $\text{COME}_2$ , 20—22% of  $\text{BuOH}$ , and traces of  $\text{EtOH}$ ,  $\text{H}_2$ ,  $\text{CO}_2$ ,  $\text{H}_2\text{S}$ , and org. acids. It utilises animal or vegetable protein, peptone, glutamic acid, and  $\text{NH}_4$  salts. It reduces  $\text{NaNO}_2$ ,  $\text{Na}_2\text{SO}_3$ ,  $\text{Na}_2\text{S}_2\text{O}_3$ , methylene-blue, and Me-red.

J. N. A.

**Synthesis of cellulose by *Acetobacter xylinum* from various polyalcohols.** Y. KHOUVINE (Bull. Soc. Chim. biol., 1936, 18, 1325—1335).—The yield of cellulose by *A. xylinum* cultured in media containing different polyalcohols ( $\text{C}_3$ — $\text{C}_7$ ) was highest with arabitol (I) and least with erythritol,  $\alpha$ - and  $\beta$ -glucoheptitol, and perseitol. In the  $\text{C}_6$  group, dulcitol (II) and mannitol (III) were more productive than sorbitol. The ratio of  $\text{CO}_2$  produced to  $\text{O}_2$  consumed corresponded with that required for combustion of the alcohol in the case of (I), (II), and (III) whereas in the other cases,  $\text{O}_2$  was apparently used chiefly in the synthetic processes. In general the yield of ketose corresponded with 80—90% of the alcohol consumed. In the case of heptitols, a substance which reduced alkaline Cu reagent in the cold without giving a  $\text{NaHSO}_3$  compound was present in addition to the expected ketose.

H. D.

**Nodule-bacteria. X. Influence of stimulating substances, especially alkaloids, on growth and morphology of nodule-bacteria.** A. ITANO and A. MATSUURA (J. Agric. Chem. Soc. Japan, 1936, 12, 604—621).—Guanidine (I), morphine hydrochloride (II), and anthraquinone were not harmful to growth;  $C_5H_5N$  and strychnine were slightly toxic, whilst quinine and, to a smaller extent, brucine and quinine prohibited growth. No correlation occurred between concn. of stimulant and degree of morphological variation. Caffeine was most effective in producing large bacteroids in all strains of bacteria, whilst (I) and (II) were effective only in certain cases. J. N. A.

**Morphology and physiology of soil *Azotobacter*.** S. WINOGRADSKY (Compt. rend., 1936, 203, 10—13; cf. A., 1932, 437).—*Azotobacter* (I) grown on  $SiO_2$  gel can utilise not only sugars but alcohols, and fatty acids (and their salts) with 2—4 C, which are end products of fermentation, and in the absence of  $NH_3$ - or  $NO_3$ -N grow to the exclusion of other bacterial strains. Benzoates are not utilised probably because of their low concn. in soil. Different strains of (I), though belonging to the same subgroup, show considerable adaptability to, and divergence in, their choice of nutrient media, and by making cultures of different composition with respect to the source of C, pure strains of (I) are obtained. J. L. D.

**Decomposition of adenine compounds by bacteria.** C. LUTWAK-MANN (Biochem. J., 1936, 30, 1405—1412).—Fresh and sterilised (PhMe) suspensions of *B. coli* (and certain other bacteria) aerobically and anaerobically deaminate adenosine (I) and adenine (II) and deaminate and dephosphorylate adenosinetriphosphoric acid (III) (optimal  $pH$  7.2) and muscle- (IV) and yeast-adenylic acid (V) with production of hypoxanthine but not of ribose. Dephosphorylation probably precedes deamination in (III) and (IV). The decomp. of (III) is accelerated, but that of (I) and (IV) is unaffected by  $Mg^{++}$ . The decomp. of (V) proceeds at a different rate from that of (IV) especially with *B. coli* grown in aq. glucose. NaF and  $CH_2I-CO_2H$  do not inhibit the decomp. of (III), (IV), and (V). (I) is more rapidly deaminated (optimal  $pH$  8.8) than (II) and than other (II) derivatives. Deamination of (I) and (II) is stimulated by  $PO_4'''$  (and  $AsO_4'''$ ), that of (II) being very incomplete (20%) in absence of  $PO_4'''$ . (III), but not adenylic acid, occurs in *B. coli*. W. McC.

**Spectrum of light emitted by *Photobacterium phosphoreum* and by some chemiluminescent reactions.** J. G. EYMERS and K. L. VAN SCHOUWENBURG (Enzymologia, 1936, 1, 107—119).—The spectral energy distribution of the bacterium is independent of external conditions and identical with that of dimethyldiacridyl nitrate during oxidation and fluorescence. Data for 3-aminophthalhydrazide are also given. E. D. Y.

**Geological significance of thermophilic bacteria.**—See this vol., 1226.

**Extraction of bacteriophage *coli* (S) by ether.** J. VOET (Compt. rend. Soc. Biol., 1936, 122, 1248—1249).—The lytic principle is insol. in  $Et_2O$ . H. G. R.

**Action of heavy water on bacteria.** K. HANSEN and E. BLEGEN (Klin. Woch., 1935, 14, 1113; Chem. Zentr., 1935, ii, 3351).—92—94%  $D_2O$  showed no sign of toxic action on staphylococci or typhus bacilli in 70 days. J. S. A.

**Avidity of solusalvarsan.** R. SCHNITZER (Wien. med. Woch., 1935, 85, 1063—1065; Chem. Zentr., 1935, ii, 3406).—Solusalvarsan acts on trypanosomes which have low sensitivity towards other As compounds as a result of As fixation. A. G. P.

**Chemistry of the ductless glands.** E. C. DODDS (Chem. and Ind., 1936, 642—646).—A lecture.

**Chemical structure in relationship to hormone and biological activity.** E. C. DODDS (Helv. Chim. Acta, 1936, 19, Spec. No., 49—58).—A lecture.

**Biochemistry of the germinal gland hormones.** A. BUTENANDT (Naturwiss., 1936, 24, 529—536, 545—552).—A lecture.

**Subconjunctival iron deposits after adrenaline injections.** T. GUNDERSON (Amer. J. Ophthalmol., 1934, 17, 807—808).—The deposits remaining at the site of injections consist of complex salts formed from  $FeCl_3$  and adrenaline (I). Fe is dissolved from hypodermic needles by (I) hydrochloride ( $pH$  5.6).

CH. ABS. (p)

**Hormone content of the pituitary of the blue whale (*Balaenoptera Sibbaldii*).** III. Growth hormone. J. VALSO (Klin. Woch., 1935, 14, 1183—1184; Chem. Zentr., 1935, ii, 3668; cf. A., 1935, 1544).—The growth hormone content per unit wt. of anterior pituitary is of the same order as that in cattle. A. G. P.

**Evaluation of the thyrotropic hormone of the human pituitary.** R. MÜLLER, H. EITEL, and A. LOESER (Klin. Woch., 1935, 14, 1296; Chem. Zentr., 1935, ii, 3399—3400).—The presence of the hormone in the human pituitary is demonstrated (guinea-pig test). The amount is not related to age or sex, or to the structure of the thyroid, but is high in certain diseases. A. G. P.

**Effect of sex hormones on the vitamin-C content of the adrenals and liver of guinea-pigs.** J. MOSONYI (Z. physiol. Chem., 1936, 242, 158—164).—The vitamin-C content of these organs of male guinea-pigs is reduced 30—40% by injection of the male hormone (I) and that of the organs of females is equally reduced by injection of follicular hormone (II). (I) has no effect on the -C content in females but (II) has a considerable reducing effect on the -C content of male organs. W. McC.

**Influence of menformone treatment on the urinary elimination of the male hormone.** F. DINGEMANSE [with H. BORCHARDT] (Acta Brev. neerl. Physiol., 1935, 5, 94—97; Chem. Zentr., 1935, ii, 3668).—Administration of menformone to man had no influence on the amount of male hormone in the urine. A. G. P.

**Effect of the crystalline male hormone on the histological structure of the comb in capons.** F. DESSAU (Acta Brev. neerl. Physiol., 1935, 5, 94; Chem. Zentr., 1935, ii, 3668).—Application to the

comb of androsterone or testosterone for 14 days stimulated its growth. A. G. P.

**Action of various male hormones on hypophysectomised animals.** J. FREUD (Acta Brev. neerl. Physiol., 1935, 5, 97—98; Chem. Zentr., 1935, ii, 3668).—Androsterone, with or without an uncharacterised substance (X) from testicles, has no action on hypophysectomised castrated male rats. Dihydroandrosterone and a conc. testosterone prep. produced positive effects which were intensified by addition of X. A. G. P.

**Effect of male sex hormone on respiration of sex-organs in castrated rats.** Y. WANG, H. WU, and C. Y. CHOU (Chinese J. Physiol., 1936, 10, 403—405).—The respiration rates (measured on surviving tissue after decapitation) of the seminal vesicles, preputial gland, and prostate of rats are lower in castrated than in normal rats but are increased (especially in the seminal vesicles) by prior administration of male sex hormone. W. O. K.

**Bi-sexual hormone (dehydroandrosterone).** D. VAN STOLK and H. PÉNAU (J. Pharm. Chim., 1936, [viii], 24, 155—162).—4 mg. of dehydroandrosterone (I) when injected simultaneously with  $1 \times 10^{-6}$  g. of folliculin (II) into castrated rats completely masked the action of (II). The active threshold for (I) is approx. 2 mg. for rats standardised to  $1.5 \times 10^{-6}$  g. of (II). Transformation of male into female hormones by dehydrogenation is not effected in the ovary. The constitution and physiological action of some sex hormones are discussed. J. N. A.

**Action of follicular hormone on bones. I. Variation in weight. II. Calcium content.** E. LIPPMAHN and U. DACHA (Boll. Soc. ital. Biol. sperim., 1936, 11, 79—81, 81—82).—I. Injection of large doses of the hormone into rabbits fed on diets rich in Ca increases the content of org. matter (loss on ashing) in the bones; with diets poor in Ca, the results are inconclusive.

II. With both diets, the bone-Ca tends to increase. F. O. H.

**Follicular content of urine in childbed.** G. TATA (Russ. Clin. Terap. Sci. affini, 1935, 34, 115—123; Chem. Zentr., 1935, ii, 3399).—A direct relationship is indicated between the *post partum* elimination of folliculin and the reappearance of menstruation. A. G. P.

**Acid-hydrolysable combined form of pregnandiol in human pregnancy urine.** A. D. ODELL and G. F. MARRIAN (Biochem. J., 1936, 30, 1533—1535).—Bu<sup>4</sup>OH extract of the urine after washing with aq. NaOH contains combined pregnandiol (I) insol. in Et<sub>2</sub>O. The complex is stable to hot alkali but is hydrolysed by hot acid. The best yield of crude free (I) was obtained by heating for 2 hr. at 120° at  $p_H$  1.5. (I) is slowly decomposed by prolonged boiling in aq. acid. W. McC.

**Urine of ovariectomised women contains only the auxogenic factor.** E. GUYÉNOT, E. HELD, A. MOZKOWSKA, and H. DE STOUTZ (Compt. rend. Soc. Biol., 1936, 122, 1152—1154). H. G. R.

**Synthetic preparation of oestrone (theelin).**—See this vol., 1256.

**Oestrogenic activity of synthetic polycyclic compounds.**—See this vol., 1247.

**Blood-lactic acid following administration of insulin in cats without the adrenal medulla.** A. H. SCOTT and B. N. BERG (J. Biol. Chem., 1936, 115, 163—169).—The blood-lactic acid curve closely follows that of the blood-sugar. J. N. A.

**Relation of the adrenal medulla to the effect of insulin on purine metabolism.** P. S. LARSON and G. BREWER (J. Biol. Chem., 1936, 115, 279—284; cf. A., 1935, 790).—Adrenalectomy prevents the increased excretion of allantoin by dogs due to injection of insulin, but is without influence on that due to adrenaline injection. H. D.

**Glucagon, the hyperglycæmia-producing substance of the pancreas.** M. BÜRGER and W. BRANDT (Z. ges. exp. Med., 1935, 96, 375—397; Chem. Zentr., 1935, ii, 3401).—The initial increase in blood-sugar caused by technical preps. but not by cryst. insulin (I) is due to glucagon (II). A conc. prep. of (II) is described. (II) is similar to (I) in physical and chemical properties and composition, but differs from it in not being inactivated by NaOH or cysteine. A. G. P.

**Influence of insulin on experimental lipæmia.** A. I. LEWIN (Z. ges. exp. Med., 1935, 96, 532—547; Chem. Zentr., 1935, ii, 3400—3401).—Administration to dogs of cholesterol (I) in vegetable oil increases the lipin content of the blood with accompanying hypercholesterolaemia. The latter diminishes after cessation of (I) treatment or on administration of insulin (II). In normal lipæmia and hypercholesterolaemia large dosages of (I) are necessary to produce this effect. An antagonistic action between blood-sugar and -(I) is indicated. No evidence of the conversion of fat into carbohydrate in the blood under these conditions was obtained. A. G. P.

**Habituation to insulin.** F. MAINZER and W. JOEL (Wien. klin. Woch., 1935, 48, 1040—1043; Chem. Zentr., 1935, ii, 3669—3670).—During insulin cures the dosage is necessarily increased. Initial symptoms of overdosage do not appear at later stages even with larger doses. The blood-sugar curve returns more quickly to normal. After interruption of treatment carbohydrate tolerance is lowered, although the hypoglycæmia produced by insulin and the rapidity of its appearance are not affected by acclimatisation. A. G. P.

**Variations in the chlorine content of the blood and nervous system [of rabbits] under the influence of insulin.** J. GARCIA-BLANCO and C. MASA (Anal. Fis. Quím., 1934, 32, 1021—1027).—The Cl content of the blood increases markedly, whereas that of the centre of the brain and that of the cerebellum increase only slightly and that of the cerebral cortex not appreciably. D. R. D.

**Synthesis of peptides. Structure and amide-nitrogen of insulin.**—See this vol., 1236.

**Thyroid function and detection of thyroid hormone in pregnancy.** (A) W. NEUWEILER. (B) K. J. ANSELMINO and F. HOFFMANN (Arch. Gynakol., 1935, 159, 574—579, 580—584; Chem. Zentr., 1935, ii, 3669).—(A) The work of Anselmino

and Hoffmann (A., 1935, 1270) is criticised. Hyperthyroidism is not a normal condition of pregnancy. Increased production by the thyroid is conditioned by the greater hormone requirement in pregnancy.

(B) A reply. A. G. P.

**Occurrence in the thyroid gland of a substance containing iodine and having antithyroxine activity.** I. ABELIN (Biochem. Z., 1936, 286, 160—181).—A peptone containing I and free from thyroxine was isolated from the Ba(OH)<sub>2</sub>-hydrolysate of thyroid gland tissue. The substance is extremely active, causes lowering of basal metabolism and general improvement of hyperthyroidised animals, can be given orally, and on further degradation yields di-iodotyrosine. The effect cannot be explained by I content. P. W. C.

**Heart size during and after feeding thyreoidin.** K. SECHER and J. VESTERDAL-JORGENSEN (Acta med. Scand., 1935, 86, 76—81; Chem. Zentr., 1935, ii, 3400).—Heart-wt. increases 4—8% during feeding of thyreoidin and slowly regains normal wt. on cessation of feeding. A. G. P.

**Combined action of thymus and irradiated ergosterol and the thymus of ergosterol-treated animals on experimental rickets.** M. MESSINI (Boll. Soc. ital. Biol. sperim., 1932, 7, 941—944; Chem. Zentr., 1935, ii, 3671).—Simultaneous administration of thymus extract accelerated the curative action of ergosterol (I). Thymus from animals pretreated with (I) was more active than that of normal animals, in respect of improved Ca fixation. A. G. P.

**Healing of bone fractures in relation to the effect of thymus and the lime-fixing vitamin.** M. MESSINI and M. COPPO (Boll. Soc. ital. Biol. sperim., 1932, 7, 947—950; Chem. Zentr., 1935, ii, 3671).—Thymus deficiency retards healing and its absence prevents the beneficial action of irradiated ergosterol. A. G. P.

**Occurrence of callicrein in salivary glands and saliva.** E. WERLE and P. VON RODEN (Biochem. Z., 1936, 286, 213—219).—Submaxillary saliva always contains callicrein (I) in considerable amounts, the amount in man and dog being < and in pig, ox, and cat > that in the respective pancreatic juice. (I) is present in smaller amounts in parotid and sublingual saliva, and is absent from parotid saliva of ox. P. W. C.

**Antigonadotropic action of epiphysan.** P. ENGEL (Wien. klin. Woch., 1935, 48, 1160—1161; Chem. Zentr., 1935, ii, 3401).—Epiphysan, from the pineal body of cattle, contains 80 rat units of the hormone per ampoule. A. G. P.

**Changes in carotene-vitamin-A economy in myxoedema and in cretins.** H. WENDT (Munch. med. Woch., 1935, 82, 1679—1681; Chem. Zentr., 1935, ii, 3670).—In human hyperthyrosis there is a marked decrease in carotene (I) and (especially) vitamin-A in serum. Vals. increase after administration of I, or after thyroid operation. In exophthalmic goitre administration of large amounts of -A induce considerable wt.-increases and a return of basal exchange to nearly normal vals. In myxo-

dema the transition of (I) into -A is disturbed when large amounts of (I) are given. In cretins serum-A is low. A. G. P.

**Carotene and vitamin-A.** B. BOTTA (Boll. Soc. ital. Biol. sperim., 1932, 7, 907—911; Chem. Zentr., 1935, ii, 3670).—Pure carotene possesses, in itself, all the biological properties of vitamin-A. A. G. P.

**Microscopical detection of vitamin-A in animal tissues. Paraplasmaic liver-cell inclusions.** III. F. R. VON QUERNER (Klin. Woch., 1935, 14, 1213—1217; Chem. Zentr., 1935, ii, 3670—3671).—Fatty inclusions in liver parenchyma, adrenals, pituitary, and retinal fat globules contain a microscopically fluorescent substance, destroyed by ultraviolet light and generally exhibiting spectral properties resembling those of vitamin-A. None occurs in rats receiving an -A-free diet. It is regarded as a storage form corresponding with factor A. A. G. P.

**Blood-sugar level in avitaminosis-A.** B. BOTTA (Boll. Soc. ital. Biol. sperim., 1932, 7, 912—916; Chem. Zentr., 1935, ii, 3670).—A vitaminosis-A probably induces a change in carbohydrate metabolism. A. G. P.

**Hypervitaminosis-B.** V. Complement action of the blood. L. BUTTURINI and R. VAILATI. VI. Cholesterolæmia. VII. Glycolytic activity of the blood. L. BUTTURINI and D. PENSOTTI. VIII. Variations in glycæmia. A. ALLEGRI (Boll. Soc. ital. Biol. sperim., 1936, 11, 36—39, 39—40, 41—42, 42—45).—V. Hypervitaminosis-B in rabbits due to crude vitamin-B preps. has an anti-complementary action in hæmolysis; cryst. -B, however, is ineffective.

VI. Blood-cholesterol is increased up to >100% by administration of large amounts of -B.

VII. Blood-glycolysis increases to a varying extent.

VIII. Blood-sugar either rises or falls, alimentary hyperglycæmia is intensified and accelerated, whilst adrenaline hyperglycæmia (especially with large doses) is diminished. F. O. H.

**Effect of extra supply of vitamin-B<sub>1</sub> on children.** M. ISHII (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 581—589).—Addition of purified vitamin-B<sub>1</sub> to the normal diet of children slightly increased the rate of growth. W. O. K.

**Synthesis of vitamin-B<sub>1</sub>.**—See this vol., 1276.

**Mechanism of formation of vitamin-C in the [eye] lens.** H. K. MÜLLER (Klin. Woch., 1935, 14, 1498—1499; Chem. Zentr., 1935, ii, 3671).—Synthesis of -C in the lens probably involves phosphorylation of sugar under the influence of glutathione. A. G. P.

**Ascorbic acid as catalyst in the oxidation of unsaturated fats.** P. HOLTZ (Arch. exp. Path. Pharm., 1936, 182, 98—108).—Autoxidation of linseed oil (emulsified with aq. gum) is accelerated by addition of normal (but not oxidised) ascorbic acid (I). The effect, which at  $p_H$  7.4 is > that at  $p_H$  5.0, is inhibited by HCN and also by CuSO<sub>4</sub>, the *per-se* accelerating action of which is also inhibited. The disappearance of the inhibitory action of reduced (I)+CuSO<sub>4</sub> with time is explained by the high catalytic activity of oxidised (I)+CuSO<sub>4</sub>. The

bearing of the results on *in-vivo* processes is discussed. F. O. H.

**Induction effect of ascorbic acid on the oxidation of sugar.** P. HOLTZ (Arch. exp. Path. Pharm., 1936, 182, 109—111).—The spontaneous oxidation of fructose, glucose (in presence of Cu), and glyceraldehyde in neutral  $\text{PO}_4'''$  buffer is accelerated by presence of ascorbic acid, the action of which, however, is not truly catalytic as it is itself at least partly oxidised. F. O. H.

**Ratio of dehydroascorbic to ascorbic acid in tissues after administration of thyroxine.** E. MARTINI and F. COPELLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 73—74).—Administration of thyroxine to guinea-pigs decreases the ascorbic acid and increases the dehydroascorbic acid content of liver and adrenals. F. O. H.

**Ratio of dehydroascorbic to ascorbic acid in the heart after administration of parasympatheticotropic substances.** F. COPELLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 75—77).—The ratio is decreased (in guinea-pigs) by parasympathetic stimulants (*e.g.*, acetylcholine) and increased by paralytics (*e.g.*, atropine) (cf. this vol., 375). F. O. H.

**Vitamin-C content of Szechwan fruits and vegetables.** Y. T. CHANG and H. B. COLLIER (Chinese J. Physiol., 1936, 10, 435—443).—The methods of Birch *et al.* (A., 1933, 646) and Bessey and King (A., 1934, 227) have been applied to the determination of the ascorbic acid (I) content of various fruits and vegetables. The "hairy pear" (*Actinidia chinensis*) is considerably richer in (I) than the various citrus fruits. W. O. K.

**Fate of dehydroascorbic acid in the organism.** M. BULOW (Z. physiol. Chem., 1936, 242, 40—42).—Oxidised ascorbic acid (I) injected into guinea-pigs on a diet poor in (I) is reduced in the organism and stored there or excreted in the urine. In some of the organs the increase in the (I) content after injection of reduced (I) is < that after injection of oxidised (I). W. McC.

**Passage of vitamin-C into the cerebrospinal fluid and the aqueous humour.** H. GOLDMANN and W. BUSCHKE (Klin. Woch., 1935, 14, 1326; cf. Tatsumi *et al.*, this vol., 1033). R. N. C.

**Avitaminosis-C and pregnancy.** M. LAPORTA and E. RINALDI (Boll. Soc. ital. Biol. sperim., 1936, 11, 141—143).—Pregnant guinea-pigs are unable to synthesise vitamin-C (cf. Mouriquand and Schoen, Compt. rend., 1933, 197, 203). F. O. H.

**Have sucklings a specialised vitamin-C metabolism?** U. HÄHN (Z. Kinderheilk., 1935, 57, 442—445; Chem. Zentr., 1935, ii, 3404).—Urinary elimination of vitamin-C following a diminished intake affords no evidence of a specialised -C metabolism or auto-synthesis. A. G. P.

**Blood-serum, -protein, and vitamin-C.** E. SCHNEIDER and E. WIDMANN (Klin. Woch., 1935, 14, 1454—1456; Chem. Zentr., 1935, ii, 3404).—Therapeutic administration of vitamin-C lowers (but not regularly) the globulin-N and increases the albumin-N of blood without decrease in sedimentation

rate. Serum of young contains more -C than that of old animals. Hypovitaminosis is not always detectable by serum analysis. Thyrotropic hormone given with -C increases the size and wt. of the adrenals by development of the medulla. A. G. P.

**Decomposition of ascorbic acid.**—See this vol., 1231.

**Chemical determination of vitamin-C.** Z. KOŁODZIEJSKA (Arch. Chem. Farm., 1934, 1, 244—252).—Tillmans' reagent gives results in agreement with biological assay for a no. of fruit juices. In some juices, oxidising and reducing agents other than ascorbic acid may vitiate results, and biological methods are necessary. CH. ABS. (p)

**Formation of vitamin-D by cathode rays.** R. M. HOFFMAN and F. DANIELS (J. Biol. Chem., 1936, 115, 119—130).—Ergosterol (I) acquires antirachitic properties when subjected to high-voltage cathode rays. The effect due to accompanying X- and ultra-violet rays is small. The cathode rays also have a strong destructive action and the antirachitic potencies produced are considerably < those from ultra-violet irradiation. One high-velocity electron produces <1 mol. of vitamin-D, but decomposes about 80 mols. of (I). Anomalous effects in the early stages of activation support the view the (I) is changed into an isomeride prior to vitamin formation. J. N. A.

**Spectrographic evaluation of solutions of vitamin-D in fats.** L. FUCHS [with Z. BECK] (Pharm. Presse, 1935, 40, 411—416, 432—440, 447—449; Chem. Zentr., 1935, ii, 3671—3672).—Ultra-violet absorption spectra are examined. Preps. are preferably dissolved in benzine or 96% EtOH. Storage in air-filled vessels for 12—14 months results in 15—19% loss of activity of the solutions. Solutions in sesame oil cannot be analysed directly by this method; the interfering substance (sesamin) is removed by triple extraction with an equal vol. of 90% AcOH. With >0.3 mg. of -D per g. of oil the method becomes inaccurate. In the presence of white P, solutions of -D lost little activity during 6 months. A. G. P.

**Constitution of vitamin-D<sub>2</sub>.**—See this vol., 1247.

**Poplar bud.** G. BRUCH and E. H. WIRTH (J. Amer. Pharm. Assoc., 1936, 25, 672—682).—The morphology and histology of the buds of *Populus balsamifera*, *P. nigra*, and *P. candicans* are described. The leaf-buds are more sol. in EtOH than are the flower-buds. F. O. H.

**Frost-hardening with living cells. I. Osmotic and bound-water changes in relation to frost-resistance and the seasonal cycle.** J. LEVITT and G. W. SCARTH (Canad. J. Res., 1936, 14, C, 267—284).—The plasmolytic method is utilised to determine the osmotic pressure and the non-osmotically active portion of the cell content. Cabbage cells probably contain no bound H<sub>2</sub>O. In cells of *Catalpa* the non-active fraction occupies a relatively larger proportion of the vacuole than of the protoplasm, and its increase in the vacuole during hardening is the principal characteristic of the process. High osmotic vals. in woody plants during winter are due

not only to production of sugar from starch but also to increased bound  $H_2O$ . The latter operates by preventing the freezing of the vacuole rather than by minimising the dehydration of protoplasm.

A. G. P.

Living geranium leaf emits a fluorescent radiation which extends in the infra-red to 830  $m\mu$ . C. DHERE and O. BIERNACHER (Compt. rend., 1936, 203, 412—414; cf. A., 1935, 671).—Repetition of the previous experiment using an infra-red plate gives a band with axis at  $\lambda$  740; longer exposure gives another brilliant band with axis at  $\lambda$  812 and extending to 830.5.

J. N. A.

Hydrogen-ion phenomena in tobacco. J. CALVERT (J. Austral. Inst. Agric. Sci., 1936, 2, 83—84).—Buffer curves of aq. extracts of cured leaves and of expressed sap of fresh leaves are recorded. Differences between curves for Australian and American tobaccos are shown.

A. G. P.

Role of potassium and phosphorus in the assimilation of different forms of nitrogen by plants.—See B., 1936, 708.

Absorption of manganese by plants. II. Toxicity of manganese to various species. C. OLSEN (Compt. rend. Trav. Lab. Carlsberg, 1936, 21, No. 9, 129—145; cf. A., 1934, 1048).—In  $H_2O$  cultures growth inhibition by Mn occurs at threshold concns. of 0.5—62.5 mg. per litre according to the species of plant. Plants frequently absorb larger amounts of Mn from nutrients containing low than from those containing high [Mn]. Stimulative effects on maize are shown by 0.1—12.5 mg. of Mn per litre. Toxic effects of Mn on *Hordeum distichum* were more marked at  $pH$  4.0 than at  $pH$  6.0. The role of Mn in controlling the flora of acid soils, and the antagonism of Mn and Ca in plant nutrition, are discussed.

A. G. P.

Nitrogen metabolism of the apple fruit. III. Effect on the composition of the fruit of injecting nitrogenous compounds into the tree. A vacuum extractor. A. C. HULME and W. A. ROACH (Biochem. J., 1936, 30, 1397—1404; cf. this vol., 531).—Injection of solutions of  $NH_4NO_3$ , urea, or asparagine (I) into apple trees resulted in increased total N content and altered N distribution (increase chiefly in non-protein N) in the fruit. Fruit stored at 9.5° after detaching from trees injected with aq.  $NH_4NO_3$  or (I) did not synthesise protein whereas fruit from untreated trees synthesised considerable amounts. A rapid continuous vac. extractor of the Soxhlet type is described.

W. McC.

Comparative action of acetaldehyde vapour on the cellular structure and sugar content of some vegetable tissues. M. MASCRÉ and R. R. PARIS (Compt. rend., 1936, 203, 113—115; cf. A., 1920, i, 584).—The syringoside (I) content of privet leaves in an atm. saturated with acetaldehyde (II) is unchanged during 1 hr., but the concn. of sugar (III) increases 10%. Subsequent exposure to air for 3 hr. causes (I) to decrease by 50% and (III) to return to normal. Similar results are obtained with *Aucuba* and cherry-bay leaves, but prolonged exposure to (I) vapour abolishes the effect. The results closely

parallel the changes in cell structure (Mascre, this vol., 1165), and suggest the interdependence of the destruction of chondriosomes and the initiation of enzymic hydrolysis.

J. L. D.

*m*-Dinitrobenzene as indicator of the respiration of animal and vegetable cells. S. C. J. OLIVIER and K. EBES (Rec. trav. chim., 1936, 55, 723—726).—Gurevitch's colour reaction for detecting respiration and the production of colour by Zn-Cu reduction fail if the *m*- $C_6H_4(NO_2)_2$  (I) used is pure. *o*- (II) and *p*- $C_6H_4(NO_2)_2$  (III) give the reaction strongly in both cases and its success hitherto is due to the presence of the isomerides as impurities in the (I) used. 1 : 3 : 5- $C_6H_4(NO_2)_3$  gives no colour. The colour given by (II) is intensified by the presence of (I). The test is valid if the (I) is replaced by 0.01 g. of (II) or (III). It is also a test for the purity of (I).

R. S. C.

Cell respiration and carbon dioxide assimilation in heavy water. K. SHIBATA and A. WATANABE (Acta Phytochim., 1936, 9, 107—114).—Respiration of *Chlorella ellipsoidea* and yeast cells takes place more slowly in 86%  $D_2O$  than in  $H_2O$  and  $CO_2$  assimilation is affected similarly. The results support the theory that the processes involve activation of  $H_2O$  mols. which is more readily effected than that of  $D_2O$  mols.

H. W.

(A) Intensity of geotropic reaction as a quantitative index of the content of growth-promoting substance [in plants]. (B) Growth-promoting substance and the formative action of light on vegetation in plants. V. M. KATUNSKI (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 237—240, 241—243).—(A) Went's coleoptile technique has low sensitivity (error  $\pm 20\%$ ), largely due to lack of uniformity in the flow of growth substance (I) from the agar block to the coleoptile. More satisfactory results are obtained by placing the block symmetrically on the cut stump and, after 2—4 hr., placing the stump in a horizontal position (in darkness) and measuring the geotropic curvature.

(B) Brief exposure (1—2 min.) of etiolated oat coleoptiles to light rapidly lowered their (I) contents, which were not greatly altered by more prolonged exposure. Short exposures at intervals indicated a regeneration of (I) during darkened periods. Development of plants was directly related to the decrease in (I) caused by exposure. Etiolation is characterised by an over-production of (I), and may be controlled in glass-house practice by short-period illumination.

Plant growth-substances. XX. Production of crystalline biotin from egg-yolk. F. KOGL and B. TONNIS. XXI. Isolation of bios-I (*meso*-inositol) from yeast. F. KOGL and W. VAN HASSELT (Z. physiol. Chem., 1936, 242, 43—73, 74—80; cf. this vol., 1163).—XX. The fraction of bios-II which is adsorbed by C yields cryst. biotin (I), m.p. 148°, an  $NH_2$ -acid (or its Me ester) which stimulates the growth of yeast at dilutions of  $1 : 4 \times 10^{11}$ . (I), which yields an inactive acetate and benzoate, is obtained from the dried yolk of Chinese duck's eggs (1.1 mg. from 250 kg.; 1.8% of that present) by pptn., adsorption on animal C, elution with  $COMe_2$  and aq.

NH<sub>3</sub>, and distillation in a high vac. (b.p. 185—250°/0.001 mm.). The activity is not affected by catalytic hydrogenation but is increased by *meso*-inositol and by filtrates from the C adsorption.

XXI. Extract of autolysed yeast treated with Pb(OAc)<sub>2</sub> followed by purification with C and fractional pptn. with EtOH yields a syrup having high bio-I activity. The syrup treated with Ac<sub>2</sub>O followed by hydrolysis and re-acetylation with AcBr gives *meso*-inositol hexa-acetate, also obtained from purified extract of plasmolysed yeast by treatment with AcBr.

W. McC.

Action of oestrogenic substances on plant growth.—See B., 1936, 708.

Physiology of the incubation period in rust infections. A. I. GRETSCHUSCHNIKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 245—247).—Following infection of oats with rust, photosynthesis increased during the first few days and subsequently declined to a low level until after the appearance of pustules. The respiratory coeff. was low before sporulation, after which it increased abruptly. Intensification coincides with the appearance of urea in tissues. Fat formation in assimilatory cells was not observed.

A. G. P.

Toxins of rust (*Puccinia*). A. I. GRETSCHUSCHNIKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 335—339).—The active toxin of rust consists principally of urea and NH<sub>3</sub>. Direct introduction of NH<sub>3</sub> into leaves depresses, and that of urea intensifies, photosynthesis. Toxin extracts favour or retard photosynthesis according to the concn. applied. Both NH<sub>3</sub> and urea increase the respiratory discharge of CO<sub>2</sub>. The effects of toxin excretion on plant metabolism are such as to prevent the mutual poisoning of the symbiotic organisms.

A. G. P.

Physiology of spike disease of sandal. B. N. SASTRI (Proc. Indian Acad. Sci., 1936, 3, B, 444—459).—Tissue fluids of resistant varieties are characterised by low acidity and poor oxidase activity.

A. G. P.

Composition of (A) *Artemisia terre-alba*. L. DANILEVSKI. (B) *A. salina*. G. V. LAZUREVSKI. (C) *A. juncea*. (D) *A. turanica*. Z. MANULKIN (Acta Univ. Asiae Med., 1935, No. 9, 5—8, 9—11, 12—13, 14—16).—(A) The air-dry plant contains H<sub>2</sub>O 8.6, hemicellulose (I) 22.2, cellulose (II) 20.2, lignin (III) 10.2, protein 4.2, ash 3.25, Et<sub>2</sub>O-sol. 6.4 [including essential oil 0.74% (cineole 8, cumene 6, borneol 7%)], H<sub>2</sub>O-sol. 21.8 (including santonin 1, tannin 6, and carbohydrates 9.9%), and EtOH-sol. substances 2.7%.

(B) The air-dry plant contains H<sub>2</sub>O 11.2, (I) 20.6, (II) 23.2, (III) 5.8, ash 4.6, Et<sub>2</sub>O-sol. 8.2 (including essential oil 0.45, wax 0.9, and resin 6.4%), H<sub>2</sub>O-sol. 22.4 (including tannin 3.6, reducing sugars 2.3, protein 1.35, and salts 1.8%), and EtOH-sol. substances 5.2%.

(C) and (D) The air-dry leaves of *A. juncea* and *turanica* contain respectively H<sub>2</sub>O 8.62 and 10.32, (I) 9.6 and 11.8, (II) 11.8 and 11.8, (III) 8.5 and 7.7, ash 5.37 and 5.79, Et<sub>2</sub>O-sol. 11.3 and 14.1 (including 1.05 and 0.69% of essential oil), H<sub>2</sub>O-sol. 27.3 and 27.3 (including reducing sugars 2.24 and 4.01, protein 5.75

and 6.37, salts 3.54 and 2.63, tannin 2.7 and 2.2%), and EtOH-sol. substances 2.5 and 1.9%.

R. T.

Root nodule bacteria of some tropical leguminous plants. I. Cross-inoculation with *Vigna sinensis*. O. N. ALLEN and E. K. ALLEN (Soil Sci., 1936, 42, 61—77).—Tests with a no. of tropical strains are recorded. The versatility of the cowpea group is emphasised.

A. G. P.

Composition of *Artemisia scopariaeformis*. G. LAZUREVSKI (Bull. Univ. Asie Centrale, 1934, No. 19, 41—48).—The air-dry leaves contain H<sub>2</sub>O 12.8, hemicellulose 13.3, cellulose 12.7, lignin 7.2, ash 5.3, H<sub>2</sub>O-sol. 34 (including tannins 6, salts 4.4, reducing sugars 2.2%), Et<sub>2</sub>O-sol. 12 [including essential oil 1.2 (*d*- $\alpha$ -pinene 4,  $\beta$ -pinene 30, myrcene 10%), wax 1, and resin 7.2%], and EtOH-sol. substances 5.14%.

R. T.

Degradation of pyrethrin in chrysanthemum flowers (*C. cinerariaefolium*). F. KIRIGIN (Arh. Hemiju, 1936, 10, 12—20).—An apparent fall in pyrethrin I+II content, as determined chemically, takes place during 4 months of storage; this effect is due to oxidation of accompanying unsaturated acids, and to diminished solubility of pyrethrins in light petroleum. After 20 months of storage about 45% of the insecticidal activity is lost in the dried flowers, and somewhat less in pyrethrum powder.

R. T.

Composition of (A) *Psoralea drupacea*, B., and of the oil pressed from its seeds, (B) roots of *Ferula pseudoreosolinum*, Lipsky. I. TSUKERVANIK and V. BERSUTSKI (Bull. Univ. Asie Centrale, 1935, No. 21, 49—54, 55—68).—(A) The air-dry leaves contain hemicellulose (I) 7.7, cellulose (II) 9.2, lignin (III) 5.5, protein 16.8, ash 9.7, H<sub>2</sub>O-sol. 24, Et<sub>2</sub>O-sol. substances 13.8%, the roots contain 8.9% of H<sub>2</sub>O-sol. products, and the seeds contain (I) 6.8, (II) 8.3, (III) 4.1, ash 6.0, H<sub>2</sub>O-sol. 23.5, EtOH-sol. 2.1, and Et<sub>2</sub>O-sol. substances 15.4%. The Et<sub>2</sub>O extract of the seeds yields a fatty oil, containing saturated (palmitic, stearic) 8, and unsaturated acids (oleic, linoleic, linolenic) 80, resins 4.1, and unsaponifiable 5.0%.

(B) [with C. V. BRUTZEVA and B. I. AJZIKOVITSCH]. The air-dry root contains (I) 11, (II) 12.4, (III) 4.3, pentosans 6.4, pectins 9.6, starch 7.19, mono- 2.11, and di-saccharides 8.86, protein 7.37, ash 5.82, H<sub>2</sub>O-sol. 29.6, EtOH-sol. 1.9, and Et<sub>2</sub>O-sol. substances 15.9% [including resin 12.63 (acids, including podocarpic, 6.1, phenols 62.5, and neutral constituents 29.5%), essential oil 3.3 (*d*- $\alpha$ -pinene 90, *d*- $\beta$ -phellandrene 5%)].

R. T.

Fixed oil of poke root. S. W. GOLDSTEIN and G. L. JENKINS (J. Amer. Pharm. Assoc., 1936, 25, 636—641).—Fractionation of the fatty oil (*d*<sub>4</sub><sup>20</sup> 0.9209, [ $\alpha$ ]<sub>D</sub><sup>20</sup> +13°, *n*<sub>D</sub><sup>20</sup> 1.4741, acid val. 71.97, sap. val. 139.43, ester val. 67.46, I val. 69.14) obtained by petrol extraction of roots of *Phytolacca americana* yields fatty acids (arachidic 5.91, palmitic 8.63, margaric 4.19, hydroxymyristic, 0.72%; also oleic and acids of low mol. wt.), hentriacontane, a sterol-like compound C<sub>23</sub>H<sub>40</sub>O, m.p. 107—108°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +70.0° in CHCl<sub>3</sub>, containing no OH, and *phytolaccasterol*, C<sub>30</sub>H<sub>50</sub>O, H<sub>2</sub>O, m.p. 169—170°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> +35.0° in CHCl<sub>3</sub> (Ac derivative, m.p. 183—183.5°).

F. O. H.

**Phytochemistry of *Monarda pectinata*, Nutt. I. [Dried] herb.** J. B. BURT (J. Amer. Pharm. Assoc., 1936, 25, 602—606).—Data are tabulated of the H<sub>2</sub>O content, fractions sol. in org. solvents, H<sub>2</sub>O, acid, and alkali, and ash constituents of flower, leaf, stem, and root. F. O. H.

**Composition of pineapples.** J. C. BODENSTEIN (Union S. Africa Dept. Agric. Forestry Sci. Bull., 1936, No. 153, 14 pp.).—Analyses are recorded. Sucrose is the principal sugar in the juice, and the ratio, fructose/glucose is approx 0.8. A negative correlation is established between the K and Ca contents of the ash of the whole fruit. A. G. P.

**Capillary distribution of plant constituents.** See B., 1936, 812.

**Iron in vegetable ashes.** G. BERTRAND (Compt. rend., 1936, 203, 371—372).—The occurrence of small nodules of Fe in vegetable ashes is attributed to local reduction. R. S.

**Iodine content of some marine algae of the Shantung coast.** T. H. TANG, F. C. KOÜ, and P. S. TANG (Chinese J. Physiol., 1936, 10, 377—378).—The I content of 14 marine algae varies from 16.8 to 462.0 p.p.m. (calc. on dry wt.). W. O. K.

**Unsaponifiable matter of algal fats. II. Pelvesterol from *Iligikia fusiformis* (Harv.), Okam.** K. SHIRAHAMA (J. Agric. Chem. Soc. Japan, 1936, 12, 521—522).—The crude fat gave 9% of pelvesterol, m.p. 122°,  $[\alpha]_D -39.6^\circ$  (acetate, m.p. 118.5°,  $[\alpha]_D -44.1^\circ$ ; propionate, m.p. 105—106°,  $[\alpha]_D -43.1^\circ$ ). The absorption spectrum of the sterol in EtOH shows narrow bands at 295, 282.5, and 273, a wide band at 260, and a wider band at 250 m $\mu$ . J. N. A.

**Balsam pear-seed oil.** Y. TOYAMA and T. TSUCHIYA (J. Soc. Chem. Ind. Japan, 1936, 39, 220—221B).—Trichosanic acid (A., 1935, 960) has been separated from the oil. T. W. P.

**Lipins of fenugreek (*Trigonella foenum graecum*).** B. N. SASTRI and M. SREENIVASAYA (Proc. Indian Acad. Sci., 1936, 3, A, 513—518).—Fractions containing a phospholipin allied to sphingomyelin, a lecithin forming a complex with CdCl<sub>2</sub>, a C<sub>5</sub>H<sub>5</sub>N-sol. and an insol. galactolipin have been isolated from fenugreek. F. N. W.

**Production of citric acid.**—See this vol., 1231.

**Odoriferous principle of green tea. VII. Constituents of tea oil.** S. TAKEI, Y. SAKATO, and M. ONO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 626—634).—Oil from green tea contains *n*-octyl alcohol (I), geraniol (II), and an alcohol, C<sub>5</sub>H<sub>12</sub>O (4'-iododiphenylurethane, m.p. 147°), probably  $\beta$ -methylbutan- $\alpha$ -ol. The ester fraction, on hydrolysis, yields (I), (II), and octoic acid. (Cf. this vol., 125.) W. O. K.

**Constituents of mulberry tree bark. I.  $\alpha$ -Amyrin.** M. OKU (J. Agric. Chem. Soc. Japan, 1936, 12, 555—559).—The unsaponifiable matter of the bark contains  $\alpha$ -amyrin. J. N. A.

**Constituents of horse-chestnut seeds. I. Nutritive value.** R. SASAKI and M. KANDATSU (J. Agric. Chem. Soc. Japan, 1936, 12, 675—683).—Treatment of powdered whole seeds with dil. Na<sub>2</sub>CO<sub>3</sub>

removes toxic substances (e.g., glucosides), and the product can then be used as a constituent of the diet of rats, which maintain normal growth. J. N. A.

**Extraction of a crystalline substance, viburnitol, from leaves of *Viburnum tinus*, L.** H. HÉRISSEY and G. POIROT (Compt. rend., 1936, 203, 466—468).—The hot-H<sub>2</sub>O extract of leaves is hydrolysed by boiling with dil. H<sub>2</sub>SO<sub>4</sub> and neutralised. Sugars are removed by yeast fermentation and the liquor is defecated with Pb(OAc)<sub>2</sub>. Further addition of ammoniacal Pb subacetate produces a ppt. from which is obtained viburnitol, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>, m.p. 180—181°,  $[\alpha]_D -49.5^\circ$ . It is probably a cyclic polyhydroxy-compound. A. G. P.

**Phytochemistry of *Monarda pectinata*, Nutt. II. Volatile oil.** J. B. BURT (J. Amer. Pharm. Assoc., 1936, 25, 682—687).—The crude oil,  $d^{25}_4$  0.9496,  $n^{25}_D$  1.5070, from the fresh, flowering herb contains 77.68 vol.-% of phenols, fractionation of which yields carvacrol: the non-phenolic fraction yields a CHO-free oil,  $d^{24}_4$  0.97264,  $n^{25}_D$  1.4806,  $[\alpha]_D^{25} +0.759^\circ$ . F. O. H.

**Lomatol and lapachiol.**—See this vol., 1119.

**Some naturally occurring pigments of biochemical interest.** P. KARRER (Helv. Chim. Acta, 1936, 19, Spec. No., 33—48).—A lecture.

**Anthocyanin of the blue blossoms of *Hyacinthus orientalis*.** K. HAYASHI (Acta Phytochim., 1936, 9, 25—33).—Extraction of the blossoms with 1% HCl-MeOH and treatment of the extract with aq. Pb(OAc)<sub>2</sub> ppts. the Pb salt, which is decomposed with 10% HCl-MeOH. Addition of Et<sub>2</sub>O to the filtrate from the PbCl<sub>2</sub> causes separation of hyacin chloride (I), decomp. 188° after softening at 185°, which closely resembles delphin chloride from *Salvia patens*. It is hydrolysed to 2 mols. of glucose and 1 mol. of delphinidin chloride. The absorption spectrum of (I) is identical with that of awobanin-A chloride from *Commelina* blossoms. H. W.

**Anthocyanin pigments of *Pharbitis nil*.** T. KATAOKA (Acta Phytochim., 1936, 9, 35—42).—Details are given of the isolation of pelargonin from red *Pharbitis* blossoms and of its hydrolysis to pelargonidin (formerly designated pharbitidin). Similarly the pink-violet blossoms yield pæonin chloride; the terms cyanilin and cyanilidin are therefore superfluous. H. W.

**Brilliant blue F.C.F., a new dye for diagnostic gastrointestinal studies.** A. C. TAYLOR (Amer. J. Digest. Dis. Nutrition, 1934, 1, 239).—A preliminary report. CH. ABS. (p)

**Modified Wright's method for staining blood smears.** W. N. STEIL (Stain Tech., 1936, 11, 99—100).—The technique with Wright's stain has been modified to give uniform results. H. G. R.

**Aniline-blue collagen stain.** F. B. MALLORY (Stain Tech., 1936, 11, 101—102).—Phosphotungstic acid is used in place of phosphomolybdic acid and the time of staining increased. H. G. R.

**Filter of Pyrex glass and stainless steel for use with Seitz filter-pads.** B. C. J. G. KNIGHT and P. FIDES (Biochem. J., 1936, 30, 1138—1139).—

The apparatus, which avoids contamination of the filtrate with toxic metals, is described. W. O. K.

[Method for] micro-extraction of tissues *in vacuo* at the normal temperature of the animal. R. PANNIER (Compt. rend. Soc. Biol., 1936, 122, 1216—1218). H. G. R.

Determination of chlorides in biological materials. V. COLLIER, jun. (J. Biol. Chem., 1936, 115, 239—245).—Tissue is digested with KOH, acidified with  $\text{HNO}_3$ , and re-digested with KOH until clear; the solution is neutralised and  $\text{Cl}^-$  determined by Fajans' method of titrating with  $\text{AgNO}_3$  with dichlorofluorescein as indicator (A., 1924, ii, 776). H. D.

Determination of chloride in body-fluids by direct titration. C. F. M. ROSE (Biochem. J., 1936, 30, 1140—1146).— $\text{Cl}^-$  is determined in urine (decolorised with C and diluted by titration with  $\text{AgNO}_3$  with eosin-dichlorofluorescein (I) as indicator. Fluids of low protein content, e.g., milk, cerebrospinal fluid, and gastric juice, are titrated at the isoelectric point of the protein directly with (I) as indicator. With whole blood and serum the protein must be removed before titration preferably by heating in  $\text{AcOH-NaOAc}$  buffer solution. W. O. K.

Electrometric determination of iodine in blood and tissues. H. PAAL and G. MOTZ (Klin. Woch., 1935, 14, 1291—1293; Chem. Zentr., 1935, ii, 3353).—The method, although fairly accurate, is troublesome and tedious. H. N. R.

Microdetermination of lead in normal and pathological tissues. F. GALLEGU Y GÓMEZ (Anal. Fis. Quim., 1935, 33, 937—941).—The org. matter contained in 0.5—1.0 g. of dried material is decomposed with  $\text{H}_2\text{SO}_4\text{-H}_2\text{O}_2$ , and the resultant  $\text{PbSO}_4$  removed in a centrifuge, washed with aq. EtOH, dissolved in ammoniacal  $\text{NH}_4$  tartrate, and saturated with  $\text{H}_2\text{S}$ . The amount of Pb is determined colorimetrically as  $\text{PbS}$ . The error is <0.6%. Epitheliomas and carcinomas of dogs and cats which have been treated with Pb compounds have Pb contents > normal. F. R. G.

Spectrographic micro-determination of zinc [in plant material]. A. P. VANSELOW and B. M. LAURANCE (Ind. Eng. Chem. [Anal.], 1936, 8, 240—242).—The plant ash is dissolved in dil. HCl, 2 mg. of Cd as  $\text{CdSO}_4$  are added, CdS and ZnS are pptd. with  $\text{H}_2\text{S}$  at  $p_{\text{H}}$  3, and the mixed ppt. is examined spectrographically, using Cd as internal standard. The range is about 1—100 p.p.m. and the error usually 10—20%. E. S. H.

Determination of non-protein-nitrogen of tissue. M. D. MEZINCESCU and F. SZABO (J. Biol. Chem., 1936, 115, 131—138).—A method, based on extraction of the minced tissue with dil.  $\text{CCl}_3\text{-CO}_2\text{H}$  for 3 hr. at  $0^\circ$ , is described. Data obtained are compared with those by Janney's method (A., 1916, ii, 460). J. N. A.

Determination of nitrogen partition in tissues. G. B. AYRES and M. LEE (J. Biol. Chem., 1936, 115, 139—148).—Sol. proteins, albumins, and globulins are determined in a KCl-buffer extract, whilst glucose,  $\text{NH}_2$ -acids,  $\text{NH}_3$ , creatine, creatinine, reduced glutathione, urea, uric acid, allantoin, and non-protein-N

are determined in an aq.  $\text{H}_2\text{WO}_4$  extract. Determinations of glycogen, Ca, P, S, total N, fat, cystine, cysteine, methionine, ash, and  $\text{H}_2\text{O}$  are made on other samples of the tissue. Details of the methods are given. J. N. A.

Determination of residual carbon in biological fluids. W. KOCHOLATY (Biochem. Z., 1936, 286, 186—192).—A method is described and used for C determinations in various org. substances and in phosphotungstic acid filtrates of blood and urine. P. W. C.

Determination of alcohol in forensic chemistry. D. C. VUCETICH (Rev. Fac. Cienc. Quim. La Plata, 1935, 10, 37—42).—5 c.c. of liquid containing EtOH with 40 c.c. of saturated aq. picric acid in a Schloesing-Aubin apparatus are slowly distilled to half vol. into 5 c.c. of  $\text{H}_2\text{SO}_4$ . 5 c.c. of the distillate are mixed with 30 c.c. of  $\text{H}_2\text{SO}_4$  and 30 c.c. of 0.1N- $\text{K}_2\text{Cr}_2\text{O}_7$  and rapidly boiled for 5 min. When cold, the solution is diluted, KI added, and the mixture is titrated with 0.1N- $\text{Na}_2\text{S}_2\text{O}_3$ . Solutions containing 0.1% of EtOH may be determined with an error of 1%. F. R. G.

Diffusion methods in qualitative micro-analysis. Detection of acetone and alcohol in biological liquids. W. R. FEARON and D. A. WEBB (Analyst, 1936, 61, 539—540).—The Conway vapour diffusion apparatus (A., 1933, 654) adapted to the detection of  $\text{COMe}_2$  (using Nessler's reagent in the inner compartment) and EtOH [using  $\text{K}_2\text{CrO}_4\text{-HNO}_3$  (cf. A., 1932, 718)] in urine, blood, and similar liquids is a very sensitive and accurate method. E. H. S.

Colorimetric determination of reduced glutathione. T. SO (Kitasato Arch. Exp. Med., 1935, 12, 243—264).—The nitroprusside method is less influenced by various factors than is the I method. CH. ABS. (p)

Micro-colorimetric determination of benzene in blood and urine. S. J. PEARCE, H. H. SCHRENK, and W. P. YANT (U.S. Bur. Mines., Rept. Invest., 1936, No. 3302, 8 pp.).—The  $\text{C}_6\text{H}_6$  is removed by aeration from the sample of blood or urine and collected in a mixture of fuming  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  which converts it into  $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$ . The acid mixture is neutralised, extracted with 10-c.c. of  $\text{COMeEt}$ , and 1.5 c.c. of 40% NaOH is added to the extract. The reddish-purple colour which develops  $\propto$  concn. of  $m\text{-C}_6\text{H}_4(\text{NO}_2)_2$ . The method is sensitive to 0.001 mg. of  $\text{C}_6\text{H}_6$ , and has an accuracy of about  $\pm 10\%$  over a range of 0.01—0.9 mg. in 10-c.c. samples. W. O. K.

Creatine-creatinine determinations according to Folin. L. BOHUNKA (Kozl. osszehas. elet. Kortan Korebol, 1935, 26, 163—166).—Colour comparisons should be made immediately and the ratio of alkali : picric acid should be 1 : 3. Creatine changes to creatinine (I) within 15 min. at  $135^\circ$ . (I) does not decompose at this temp. CH. ABS. (p)

Determination of choline.—See this vol., 1235.

Determination of haemoglobin as globin picrate. A. BOLLIGER (Austral. J. Exp. Biol., 1936, 14, 97—99).—After pptn. of globin picrate with alcoholic picric acid, excess is titrated with methylene-blue. H. G. R.

# BRITISH CHEMICAL ABSTRACTS

## A.—PURE CHEMISTRY

NOVEMBER, 1936.

### General, Physical, and Inorganic Chemistry.

Width of stellar hydrogen lines. P. ROSSIER (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 85—86).—Widths are approx. const. and independent of the brightness of the star and of its temp. over 7000—14,000°. N. M. B.

Spectroscopic determination of [atomic] mass of deuterium from the Balmer series. A. HAGENBACH and H. GARTNER (Helv. phys. Acta, 1935, 8, 314—315; Chem. Zentr., 1935, ii, 3885).—The Balmer lines excited in the vapour of 58% heavy  $H_2O$  have satellites of shorter  $\lambda$  which are due to D. From their Rydberg const.,  $M_D/M_H=1.996$ . J. S. A.

Extension of the absorption spectrum of the hydrogen molecule. J. J. HOPFIELD (Physical Rev., 1935, [ii], 47, 788—789).—Discrete absorption lines have been observed as far as 738 Å. in  $H_2$  at low pressures. L. S. T.

Stark effect with the helium line  $\lambda$  4686. B. KULLENBERG (Z. Physik, 1936, 102, 423—427).—The Stark effect for the He line  $\lambda$  4686 Å. has been investigated for fields up to 40 kv. per cm. A. J. M.

Spectra of helium by high-frequency excitation. M. PETERSEN and H. CARL (Physical Rev., 1935, [ii], 47, 803).—Conditions of enhancement of certain singlet lines have been ascertained. L. S. T.

Spreading in the first positive bands of nitrogen. E. T. S. APPLEYARD (Proc. Physical Soc., 1936, 48, 763—771).—An experiment is described to distinguish between the theories of Maxwell (cf. A., 1932, 1185) and of Skinner (cf. A., 1933, 893) for the secondary excitation responsible for the production of spreading. The resonance radiation of N emitted from an electron beam is passed through a thin celluloid window which holds back metastable atoms; results show that part, or possibly the whole, of the secondary excitation of the first positive bands is due to collisions of the second kind with mols. in the  $a^1\Pi$  state, supporting Skinner's theory. N. M. B.

Energy of metastable nitrogen molecules. H. HAMADA (Sci. Rep. Tohoku, 1936, 25, 217—226).—From the intensity distribution in bands attributed to the metastable  $A^3\Sigma N_2$  mol., the energy of metallic spectra excited by this mol., and the intensity distribution in bands in the afterglow of active N, it is deduced that the concn. of mols. in low vibrational states among the metastable mols. is small. It is suggested that the high concn. of mols. in states  $v''=7-8$  can be deduced from the Franck-Condon principle. O. D. S.

Origin of the afterglow in active nitrogen. G. CARIO and U. STILLE (Z. Physik, 1936, 102, 317—330).—An apparatus for photography of the band systems of the N afterglow under various conditions of pressure and discharge is described. Effects of wall activation and pressure are discussed with reference to the Cario-Kaplan theory. L. G. G.

Nuclear magnetic moment of  $^{23}Na$ . L. A. WILLS and G. BREIT (Physical Rev., 1935, [ii], 47, 704—705).—A discussion. L. S. T.

Magnetic moment of the  $^{23}Na$  nucleus. W. E. SHOUPP, J. H. BARTLETT, jun., and C. G. DUNN (Physical Rev., 1935, [ii], 47, 705—706).—A discussion. This moment is probably about 2.5—3.1 nuclear magnetons. L. S. T.

Alkali-metal films transparent in the Schumann region. W. H. WATSON and D. G. HURST (Canad. J. Res., 1936, 14, A, 153—157; cf. this vol., 1039).—Na films on fluorite are transparent to  $\lambda < 2100$  Å., but show some absorption in the range 1400—1250 Å. K films show weak absorption from 1700 Å., the intensity of absorption increasing with decreasing  $\lambda$ . No evidence of transparency with Li films has been obtained. J. W. S.

Alternating intensities in the spectrum of  $P_2$ . F. A. JENKINS (Physical Rev., 1935, [ii], 47, 783). L. S. T.

Spectra of phosphorus, P II, P III, P IV. H. A. ROBINSON (Physical Rev., 1935, [ii], 47, 799; cf. this vol., 397). L. S. T.

Deep terms in ions of the isoelectronic sequence Cl I to Mn IX. S. G. WEISSBERG and P. G. KRUGER (Physical Rev., 1935, [ii], 47, 798).—Vals. of deep terms and ionisation potentials are tabulated. L. S. T.

Molecular spectra of the sulphur group. B. ROSEN and F. BOUFFIQUX (Bull. Acad. roy. Belg., 1936, [v], 22, 885—893).—The broad emission bands of  $Te_2$  vapour reported by Désirant (cf. this vol., 1040) were photographed and analysed to longer  $\lambda$ ; they resolve into narrow bands degraded towards the red. Intensity fluctuations are discussed. The new infra-red band system of  $S_2$  (cf. *ibid.*, 537) photographed at high dispersion showed that certain of the narrow bands are groups of lines of S I. An analysis of 7 bands of  $S_2$  is given. New measurements of the complex bands in the red part of the principal system of  $S_2$  are reported (cf. *ibid.*, 127). N. M. B.

Lifetimes of potassium doublets  $\lambda$  4047—4 and  $\lambda$  3447—6. D. SINCLAIR and H. W. WEBB (Physical Rev., 1936, [ii], 50, 440—445).—The life-

times were measured by the a.c. excitation method; a special NaH vac. photo-cell was used to measure the radiation from a K cell containing a hot cathode and two anodes. The K v.p. range was  $4 \times 10^{-5}$ – $10^{-2}$  mm. The respective lifetimes, accurate to 1%, were  $3.79 \times 10^{-7}$  and  $8.50 \times 10^{-7}$  sec. Radiation emitted after electron excitation followed a simple exponential law. No change of lifetime was found for the whole pressure range; this could be accounted for by assuming that only 10% of each of the  $\lambda\lambda$  groups is re-emitted at the same  $\lambda$ . N. M. B.

**Term analysis of the first spectrum of vanadium (V I).** W. F. MEGGERS and H. N. RUSSELL (J. Res. Nat. Bur. Stand., 1936, 17, 125–192).—Complete tables of the lines and terms of the V I spectrum are given, and the electronic configurations responsible for the observed terms have been identified in nearly all cases. The ionisation potential of neutral V atoms is calc. to be 6.71 volts. O. J. W.

**Connexion between the deep terms of the elements of the iron series.** M. A. CATALAN and M. T. ANTUNES (Z. Physik, 1936, 102, 432–460).—The expression for the energy of spectral terms based on the Slater method is discussed, and the energy of terms of certain configurations is calc. Empirical relationships between observed term vals. are discussed. A. J. M.

**Connexion between the Rydberg numbers of the deep terms in the iron series.** M. A. CATALAN and F. POGGIO (Z. Physik, 1936, 102, 461–479).—The observed abs. term vals. and Rydberg nos. for the  $3d^m4s$  and  $3d^m4s^2$  configurations are compared with those calc. from Catalan and Antunes' formula (see above), and a no. of empirical rules are derived. A. J. M.

**Absorption processes in the halogen spectra.** R. S. MULLIKEN (J. Chem. Physics, 1936, 4, 620–621).—The interpretation of the absorption continuum of  $\text{Br}_2$  preferred by Acton *et al.* (this vol., 1167) may apply to that of  $\text{Cl}_2$ , but is inapplicable to that of  $\text{I}_2$ . The transition  $^1\text{I} \leftarrow ^1\Sigma^+$  is not so weak in the halogens as hitherto supposed. J. G. A. G.

**Third spectrum of krypton.** C. J. HUMPHREYS (Physical Rev., 1935, [ii], 47, 799–800).—The spectrum characteristic of the  $\text{Kr}^{++}$  ion has been selected from the various Kr spectra excited in a Geissler tube discharge. 369 lines extending from 2100 to 7400 Å. have been classified as arising from 88 levels of Kr III. L. S. T.

**Hyperfine structure of Y II lines.** P. G. KRUGER and C. N. CHALLACOMBE (Physical Rev., 1935, [ii], 47, 509).—Data are tabulated. A nuclear moment of  $\frac{1}{2}$  is indicated for Y. L. S. T.

**Quenching of cadmium resonance radiation (3261) by hydrogen.** H. C. LIPSON and A. C. G. MITCHELL (Physical Rev., 1935, [ii], 47, 638).

L. S. T.

**Ultra-violet  $\text{I}_2$  fluorescence.** D. T. WARREN (Physical Rev., 1935, [ii], 47, 642).

L. S. T.

**Intensity distribution in the line emission spectrum of caesium.** F. L. MOHLER (J. Res. Nat. Bur. Stand., 1936, 17, 45–54).—The intensity dis-

tribution in the *S*, *D*, and *F* series of the Cs emission spectrum has been measured. For the *D* series intensity measurements have also been made for a columnar discharge, and for the 5466 and 5503 Å. lines the intensity variation with current and pressure is described. D. J. W.

**Paschen-Back effect in the hyperfine structure of the caesium resonance line  $\lambda 8522$  Å.** H. KOPFERMANN and H. KRÜGER (Z. Physik, 1936, 102, 527–533).—The Paschen-Back effect was investigated in the case of 16 field-parallel components of the Cs I line,  $\lambda 8522$  Å. ( $6^2S_1 - 6^2P_{3/2}$ ) using a magnetic field of 9700 Gauss. The nuclear moment of Cs is  $7/2$ . A. J. M.

**Wave-length measurements in the spectra of the neodymium arc and the standard Pfund iron arc.** G. R. HARRISON and W. W. BARTLETT (Physical Rev., 1935, [ii], 47, 799). L. S. T.

**Near infra-red spectrum of mercury. I.** O. MASAKI, K. KOBAYAKAWA, and T. MORITA (J. Sci. Hiroshima Univ., 1936, 6, 291–297).—The spectrum was photographed with supersensitised plates, and full data and classifications are tabulated. N. M. B.

**Line absorption of mercury vapour for individual hyperfine structure components of the 2537 Å. line.** K. ZUBER (Helv. phys. Acta, 1935, 8, 370–380; Chem. Zentr., 1935, ii, 3890).—Assuming that the mean life of the  $2^3P_1$  level is the same for all isotopes, the results accord with the fine structure scheme of Schüler and Keyston. J. S. A.

**Stepwise fluorescence in mercury vapour: the 3650 line.** L. A. TURNER (Physical Rev., 1935, [ii], 47, 807). L. S. T.

**Isotope effect of ionised mercury hydrides ( $\text{HgH}^+/\text{HgD}^+$ ).** S. MROZOWSKI (Z. Physik, 1936, 102, 545–547).—The results of Hori *et al.* (this vol., 1168) are not sufficiently accurate to warrant the conclusion that there are deviations from the usual isotope formula in the case of the ionised Hg hydrides. A. J. M.

**Zeeman effect of the lead line  $6p^2\ ^3P_2 - 6p.7s\ ^3P_1$  ( $\lambda 4058$  Å.).** S. SATÔ (Sci. Rep. Tôhoku, 1936, 25, 207–216). O. D. S.

**Deep terms in the spectra of Pb v and Bi VI.** G. K. SCHOEPPLE (Physical Rev., 1936, [ii], 50, 538–542; cf. A., 1935, 424; Mack, *ibid.*, 1292).—Full data for  $\lambda\lambda$ , classifications, energy levels, and transitions are tabulated for 69 terms involving 205 lines of Pb v, and 40 terms involving 94 lines of Bi VI. N. M. B.

**Paschen-Back effect. -S-P multiplets in strong fields.** P. JACQUINOT (Physical Rev., 1936, [ii], 50, 573).—The resolution of the *s* components reported by Green (cf. this vol., 653) had been previously effected (cf. A., 1935, 423). N. M. B.

**Distribution of the energy in the extreme ultra-violet of the solar spectrum.** W. W. COBLENTZ and R. STAIR (J. Res. Nat. Bur. Stand., 1936, 17, 1–6).—The distribution of energy in the extreme ultra-violet of the solar spectrum within and outside the earth's atm. has been calc. It seems

incorrect to assume that the radiation is similar to that of a black body at 6000° abs. Apparatus is described for measuring the spectral quality and total intensity of ultra-violet solar radiation by means of a photo-electric cell and filter radiometer transported aloft in sounding balloons. O. J. W.

**Ultra-violet absorption spectrum of Nova Herculis 1934.** H. E. GREEN (Month. Notices Roy. Astron. Soc., 1935, 95, 694—704).—Lines of Fe II, Ti II, Cr II, V II, and Mn II were identified.

CH. ABS. (c)

**Arcs in inert gases. III.** G. E. DOAN and W. C. SCHULTE (Physical Rev., 1935, [ii], 47, 783—784).—The non-arcing phenomenon reported (A., 1934, 935) for low-current arcs also obtains in high-current welding arcs. In A of <99.0% purity, crater formation and penetration do not occur. L. S. T.

**Processes at the cathode of arc discharges.** O. BECKEN and K. SOMMERMEYER (Z. Physik, 1936, 102, 551—561).—Two types of discharge at C and W cathodes are described, which are regarded as due to thermal and auto-electronic emission respectively. O. D. S.

**Condensed discharge.** Z. BAY (Z. Physik, 1936, 102, 507—526).—Short-lived collisions of high intensity were produced in H<sub>2</sub>, N<sub>2</sub>, Ne, and Ne-Hg mixture by the condensed discharge, and the electrical and spectral properties of the discharge were investigated. Very high c.d. were obtained, and the resulting spectra showed corresponding variations with c.d. A. J. M.

**Gas reactions in silent discharge at atmospheric pressure. I. New type of screened point discharge with transition of strong current form of discharge to a weaker.** P. A. THIESSEN and H. BARTEL (Z. tech. Physik, 1935, 16, 285—293; Chem. Zentr., 1935, ii, 3891).—The discharge characteristics are described. J. S. A.

**Photographic effective wave-length.** P. ROSIER (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 83—85).—Differences between visual and micro-photometric measurements of the distances of diffraction spectra from the central image and resulting differences of  $\lambda\lambda$  are examined mathematically. N. M. B.

**Precision X-ray wave-length measurements.** L. G. PARRATT (Physical Rev., 1935, [ii], 47, 882—883).—A discussion. L. S. T.

**Energies of X-ray photoelectrons.** L. W. ALVAREZ (Physical Rev., 1935, [ii], 47, 636).—New vals. of these energies favour the crystal rather than the grating scale of X-ray  $\lambda$  (cf. this vol., 1040). L. S. T.

**Absorption of X-rays in the wave-length range 50 to 200 X.** M. T. JONES and T. R. CUYKENDALL (Physical Rev., 1935, [ii], 47, 643).—Absorption coeffs. in this range have been measured for C, Na, Al, K, Ni, Cu, Nb, Mo, Ag, Sn, Ta, and Pb. L. S. T.

**Production of X-radiation by very fast electrons.** E. McMILLAN (Physical Rev., 1935, [ii], 47, 801).—As indicated by theory, radiation is emitted by paraffin, Al, and Pb when they stop the  $\beta$ -particles

given by active <sup>32</sup>P or by Cl activated by deuteron bombardment. L. S. T.

**K $\beta$  Spectra of chlorine and sulphur.** H. TAZAKI (J. Sci. Hiroshima Univ., 1936, 6, 299—305).—Using LiCl, NaCl, and KCl on a Cu, and S and K<sub>2</sub>SO<sub>4</sub> on an Al, anticathode, the spectra were photographed with long exposure, revealing many fine spark lines of Cl and new lines of S. Full  $\lambda\lambda$  and  $\nu/R$  and  $\sqrt{\nu}/R$  vals. are tabulated, and semi-Moseley diagrams are given and discussed. N. M. B.

**Relationships between atomic number and effect of chemical binding on the K $\alpha_{1,2}$  doublet of some of the lighter elements.** N. G. JOHNSON (Z. Physik, 1936, 102, 428—431; cf. A., 1935, 908).—The effect of chemical binding on the K $\alpha_{1,2}$  lines of <sup>12</sup>Mg and <sup>13</sup>Al has been investigated. With the compounds used there is a displacement of the lines, compared with the positions of those of the free elements, towards shorter  $\lambda\lambda$ , the effect being a max. in the case of the fluorides Na<sub>3</sub>AlF<sub>6</sub> and MgF<sub>2</sub>. The displacements for the oxides of elements of at. no. 12—16 (Mg—S) when plotted against at. no. lie on a smooth, almost rectilinear curve. A similar curve is obtained for fluorides. A. J. M.

**New lines in the K series spectrum of tungsten.** J. C. HUDSON, H. G. VOGT, and A. H. ARMSTRONG (Physical Rev., 1935, [ii], 47, 809). L. S. T.

**Widths of certain L-absorption edges.** A. E. SANDSTROM (Phil. Mag., 1936, [vii], 22, 497—513).—The effect of thickness of absorbing screen, time of exposure, and the broadening effect of the spectrograph on the width of the L-absorption edges of some elements has been examined. The full widths of the L<sub>II</sub> and L<sub>III</sub> and some L<sub>I</sub> edges of elements between Zn and Te were measured, together with their asymmetry. The latter was, in most cases, very pronounced. Curves are given showing the variation of the width of the edge with at. no. The L<sub>II</sub> and L<sub>III</sub> curves have the same shape, but the few points obtained for L<sub>I</sub> edges seem to require a different curvature. A. J. M.

**L Spectra of radium (88).** H. HULUBEI (Compt. rend., 1936, 203, 542—543; cf. this vol., 399).—Emission and absorption lines of the L spectra of Ra have been determined and the electron levels tabulated. R. S.

**K Spectra and conductivity electrons of solid and liquid aluminium.** J. FARINEAU (Compt. rend., 1936, 203, 540—541).—The  $\alpha$  bands and the short-wave limits of the  $\beta$  bands of solid and liquid Al are the same, but the structure of the bands is different in liquid Al. It is suggested that the M electrons are only loosely bound and subject to perturbations connected with the lattice structure. R. S.

**Calculation of the X-ray energy level widths of Au (79).** E. RAMBERG and F. K. RICHTMYER (Physical Rev., 1935, [ii], 47, 644; cf. A., 1935, 138).—L. S. T.

**Form and breadth of Compton lines.** H. KAPPELER (Helv. phys. Acta, 1935, 8, 314; Chem. Zentr., 1935, ii, 3361).—Data are given for N, Ne,

Li, C, and NaF. The form of the Compton line is dependent on the nature of the scattering particle.

J. S. A.

**Auger effect for Au (79) and the origin of certain L-satellites in X-ray spectra.** E. RAMBERG and F. K. RICHTMYER (Physical Rev., 1935, [ii], 47, 805).

L. S. T.

**Radiative Auger effect.** F. BLOCH and P. A. ROSS (Physical Rev., 1935, [ii], 47, 884—885).

L. S. T.

**Photo-electric properties of zinc.** C. F. DE VOE (Physical Rev., 1936, [ii], 50, 481—485).—The work function of a vac.-distilled Zn surface, corresponding with the long-wave limits 2900—2930 Å., was 4.24 volts at  $1.5 \times 10^{-8}$  mm. pressure, and decreased, with rise of air pressure, to a min. at about  $10^{-6}$  mm. and then increased. He and N<sub>2</sub> had no effect to pressures of 3 mm. and  $10^{-3}$  mm., respectively.

N. M. B.

**Free path of conductivity electrons.** A. PAPAETROU (Z. Physik, 1936, 102, 539—544).—The Bloch method of calculating electrical conductivity from the interaction between electrons and heat waves is simplified by avoiding the use of an integral equation.

A. J. M.

**Passage of fast electrons through matter.** H. J. BHABHA and W. HEITLER (Nature, 1936, 138, 401).—The probability for production of secondary electrons when a fast primary electron passes through varying thicknesses of matter has been calc. A primary electron of  $2 \times 10^9$  e.v. passing through a thickness equiv. to 1.6 cm. of Pb produces, on the average, 2 positive and 2 negative electrons with energies  $> 2 \times 10^7$  e.v.

L. S. T.

**Properties of an electron which rolls without slipping and of radius varying inversely as the velocity.** T. V. IONESCU (Compt. rend., 1936, 203, 537—539).—The properties of free and orbital electrons can be accounted for.

R. S.

**Positive and neutral rays. IV. Effective cross-sections for neutralisation.** A. ROSTAGNI (Nuovo Cim., 1935, [ii], 12, 134—153; Chem. Zentr., 1935, ii, 3362).—For the neutralisation of A<sup>+</sup>, Ne<sup>+</sup>, and He<sup>+</sup> in A, Ne, and He, respectively, the effective cross-section rises with decreasing velocity of the ions to a max. between 20 and 30 volts, and then decreases for low velocities.

J. S. A.

**Absorption and diffusion of positive rays in gases.** A. ROSTAGNI (Atti R. Accad. Sci. Torino, 1935, I, 70, 472—486; Chem. Zentr., 1935, ii, 3362).—Data are given for A<sup>+</sup>, Ne<sup>+</sup>, and He<sup>+</sup> in A, Ne, and He, respectively.

J. S. A.

**Potential for light excitation in mercury by collisions with Li<sup>+</sup>, Na<sup>+</sup>, K<sup>+</sup>, Rb<sup>+</sup>, Cs<sup>+</sup>.** O. HENLE and W. MAURER (Physikal. Z., 1936, 37, 659—661; cf. this vol., 1167).—The potentials required for the appearance of lines due to alkali metals in the light caused by collision of the ions with Hg have been determined. The potentials at which the various lines appear are: Hg < 500, Li<sup>+</sup> and Na<sup>+</sup> > 9000, K<sup>+</sup> > 9000, Rb<sup>+</sup> < 9000, Cs<sup>+</sup> about 1400 volts.

A. J. M.

**Filament sources of positive ions.** J. P. BLEWETT and E. J. JONES (Physical Rev., 1936, [ii], 50, 464—468).—Efficient filament sources of alkali-metal ions were obtained by heating synthetic alkali Al silicates. Studies of emission of the Li sources as a function of composition show that β-eucryptite, Li<sub>2</sub>O·Al<sub>2</sub>O<sub>3</sub>·2SiO<sub>2</sub>, is the most satisfactory. Ions of Mg, Ca, Sr, Ba, Al, Ga, In, Ti, V, Mn, Y, and Ce are emitted when the oxide of the respective metal is raised to white heat on a W filament. Mass-spectrograph analyses of ion beams were made; for Al, negative ions of mass 27, probably Al<sup>-</sup>, were observed.

N. M. B.

**Approximate numerical values of the atomic field and radial wave functions of the silver ion.** (MISS) M. M. BLACK (Mem. Manchester Phil. Soc., 1934—1935, 79, 29—33).—Calculations of the approx. at. field and wave functions of Ag<sup>+</sup> have been computed by the method of self-consistent field.

R. S. B.

**Products of ionisation in methane.** J. A. HIPPLE, jun., and W. BLEAKNEY (Physical Rev., 1935, [ii], 47, 802).—The ions CH<sub>4</sub><sup>+</sup>, CH<sub>3</sub><sup>+</sup>, CH<sub>2</sub><sup>+</sup>, CH<sup>+</sup>, C<sup>+</sup>, H<sub>2</sub><sup>+</sup>, and H<sup>+</sup> have been observed by the usual mass-spectrograph method. Excepting H<sub>2</sub><sup>+</sup>, which may be an impurity, these ions are primary products. The appearance potentials are 13.7, 14.7, 15.7, 23, 27, —, and 31 volts, respectively. No negative or doubly-charged ions were observed. CD<sub>4</sub> and CHD<sub>3</sub> show characteristics similar to CH<sub>4</sub>.

L. S. T.

**Separation of isotopes by centrifuging.** J. W. BEAMS and F. B. HAYNES (Physical Rev., 1936, [ii], 50, 491—492).—The possibility of adapting a new air-driven centrifuge, giving "velocity separation" as well as centrifugal separation, is investigated by experiments on N<sub>2</sub>-CO<sub>2</sub> mixtures, relative to rotor speed and design. A change in *d* of fractions of CCl<sub>4</sub> was observed.

N. M. B.

**Production of helium of mass three?** H. D. SMYTH, G. P. HARNWELL, W. BLEAKNEY, and W. W. LOZIER (Physical Rev., 1935, [ii], 47, 800—801).—A discussion of doubts concerning the interpretation of previous results (this vol., 301).

L. S. T.

**Oxygen isotopes.** W. BLEAKNEY and J. A. HIPPLE, jun. (Physical Rev., 1935, [ii], 47, 800).—Mass-spectrographic analyses of > 100 samples of O<sub>2</sub> from various sources give vals. of <sup>16</sup>O : <sup>18</sup>O around 500. Commercial O<sub>2</sub> varies in isotopic concn. from tank to tank, suggesting that refinements of some at. wt. determinations are meaningless without a simultaneous isotopic analysis. Fractionation of the O isotopes produced by electrolysis of H<sub>2</sub>O is approx. 1.01.

L. S. T.

**Chemical differences between nitrogen isotopes.** H. C. UREY and A. H. W. ATEN, jun. (Physical Rev., 1936, [ii], 50, 575; cf. Ogawa, this vol., 1079).—Preliminary results of attempted separations by fractionation and exchange reaction methods are reported.

N. M. B.

**Mass-spectrograph analysis of beryllium.** W. BLEAKNEY, J. P. BLEWETT, R. SHERR, and R. SMOLUCHOWSKI (Physical Rev., 1936, [ii], 50, 545—546).—A new ion source for positive-ray analysis was developed

in the form of a mol. beam from a hot oven; ions were produced in the beam by electron impact and focussed on the slit of the mass spectrograph by electric fields. Application to Be revealed only  $^9\text{Be}$ . The upper limit for  $^8\text{Be}$  was 1 part in 10,000.

N. M. B.

**Mass-spectrograph study of Ba, Sr, In, Ga, Li, and Na.** M. B. SAMPSON and W. BLEAKNEY (Physical Rev., 1935, [ii], 50, 456—460).—Using a  $180^\circ$ -type mass-spectrograph of 22 cm. radius with 1400 gauss magnetic field, an analysis was made of the ions from coated filaments. Peaks for Sr at 84, comprising 0.5% of the total Sr current, and for Ba at 134, comprising 1.8% of the total Ba current, are interpreted as new Sr and Ba isotopes. A third isotope of In was not found. Relative abundances of  $^{69}\text{Ga}$  and  $^{71}\text{Ga}$  were 38.8% and 61.2%, respectively.  $^6\text{Li}$  and  $^{23}\text{Na}$ , reported by Brewer (cf. this vol., 918), were not confirmed.

N. M. B.

**Variations of the at. wts. of terrestrial elements.** V. I. VERNADSKI (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 129—133).—A review and discussion of the isotopic compositions of elements.

A. J. E. W.

**Ranges of particles emitted by samarium.** L. LEWIN (Nature, 1936, 138, 326).—In addition to  $\alpha$ -particles of 1.150 cm. range, ionising particles of 0.13 cm. range contributing approx. 35% of the total ionisation due to  $\alpha$ -particles are emitted by Sm.

L. S. T.

**Emission of protons by samarium.** J. A. BEARDEN and W. R. KANNE (Physical Rev., 1935, [ii], 47, 639).—Two groups of  $\alpha$ -particles (cf. this vol., 130) differing in range by 2 mm., but no proton emission (cf. A., 1934, 713), have now been detected.

L. S. T.

**Diffusion of radioactive atoms.** J. A. GRAY and J. F. HINDS (Physical Rev., 1935, [ii], 47, 813).—The relative rates of deposit of Ra-D, -E, and -F on plates placed above a source of Ra-(D+E+F) from Rn have been compared with the equilibrium vals. These atoms diffuse through thin metal foils, the Ra-E more easily than -D and -F.

L. S. T.

**Excitation curves for fluorine and lithium.** L. R. HAFSTAD, N. P. HEYDENBURG, and M. A. TUVE (Physical Rev., 1936, [ii], 50, 504—514; cf. A., 1935, 1296, 1297).—Results are given of observations of increased accuracy, using a corona-free, 10,000-megohm voltmeter-resistor for voltage measurements, on the  $\alpha$ -particles from Li and the  $\gamma$ -rays from Li and F, when bombarded with protons of energies up to 1000 kv. A weak multiplet structure in F is indicated in the region 500—700 kv., with a broad but fairly prominent "resonance" at 650—700 kv.

N. M. B.

**$\alpha$ -Activity excited in cerium and caesium by neutrons.** E. FUNFER (Physikal. Z., 1936, 37, 693—694).—Contrary to Dopel (this vol., 659) no marked activity could be excited in Ce (using  $\text{CeO}_2$ ) or in Cs (using  $\text{CsCl}$ ) by bombardment with neutrons.

A. J. M.

**High-frequency parallel rod method for the determination of  $\alpha$ -ray speeds.** T. R. WILKINS,

W. RAYTON, and H. ST. HELENS (Physical Rev., 1935, [ii], 47, 812).

L. S. T.

**$\alpha$ -Ray and proton tracks in photographic emulsions.** T. R. WILKINS, W. RAYTON, and H. ST. HELENS (Physical Rev., 1935, [ii], 47, 812).— $\alpha$ -Ray and proton tracks showing Rutherford scattering have been observed; an analysis of the tracks observed when collimated  $\alpha$ -rays fall on a  $\text{H}_2\text{CrO}_4$ -sensitised emulsion has been made.

L. S. T.

**$\alpha$ -Particle scattering by deuterons and protons.** H. MARGENAU and E. POLLARD (Physical Rev., 1935, [ii], 47, 640).—For  $\alpha$ -particle collision with protons anomalous scattering is detected at the range of a 1.7 cm.  $\alpha$ -particle; for D the  $\alpha$ -particle range is 1.3—1.6 cm.

L. S. T.

**Precise measurement of three radium-B  $\beta$ -particle energies.** F. T. ROGERS, jun. (Physical Rev., 1936, [ii], 50, 515—523; cf. Scott, A., 1934, 1284).—Vals. of  $H_\rho$ , where  $H$  is the magnetic field required to produce a radius  $\rho$  of curvature of path, measured for the three most intense Ra-B  $\beta$ -particle lines by a precise magnetic spectrograph method, are 1406.0, 1671.1, and 1931.5 gauss cm., accurate to 1 part in 3000, and the corresponding energies are  $1.512 \times 10^5$ ,  $2.044 \times 10^5$ , and  $2.610 \times 10^5$  e.v.

N. M. B.

**Scattering of  $\gamma$ -rays.** R. S. SHANKLAND (Physical Rev., 1936, [ii], 50, 571).—Experiments previously described (cf. this vol., 265) are extended with modified apparatus.

N. M. B.

**$\gamma$ -Radioactivity with continuous spectrum. New unitary field theory.** E. C. G. STUECKELBERG (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 64—69).—Energy considerations are discussed. A new field theory, analogous to that of Born, uses spinors instead of vectors, and considers the electron, neutrino, proton, and neutron as different quantum states of a single elementary particle.

N. M. B.

**Neutron effects in a photographic emulsion.** D. W. MUELLER and H. A. BARTON (Physical Rev., 1935, [ii], 47, 796; cf. A., 1935, 1441).—The proton and  $\alpha$ -particle tracks produced by the passage of neutrons through photographic emulsions have been investigated.

L. S. T.

**Absorption cross-sections of thermal neutrons.** C. T. ZAHN, E. L. HARRINGTON, and S. GOUDSMIT (Physical Rev., 1936, [ii], 50, 570).—The back scattering of slow neutrons from a thick layer is measured by immersing a detector foil in a liquid and comparing the activity caused by the neutrons for the bare foil with that when the neutrons have been screened on one side. Hence the absorption cross-sections can be calc. (cf. Bayley, below). Approx. results are obtained with dil. Cd salt solutions.

N. M. B.

**Diffusion of slow neutrons.** D. S. BAYLEY, B. R. CURTIS, E. R. GAERTNER, and S. GOUDSMIT (Physical Rev., 1936, [ii], 50, 461—463).—The effect of Ag, Cu, C, and Cd on the diffusion in  $\text{H}_2\text{O}$  of slow neutrons, as indicated by the decrease of activity of Rh and Ag foil detectors, was investigated and plotted. The interpretation of data on the back

scattering of neutrons (cf. Mitchell, this vol., 541) is discussed. N. M. B.

**Behaviour of slow neutrons at different temperatures.** E. AMALDI and E. SEGRE (Physical Rev., 1936, [ii], 50, 571).—Measurements of the reflexion coeff. of paraffin for thermal neutrons show that the result is the same at liquid air and at room temp. Hence the mean free path and mean life of the neutrons in paraffin cannot be independent of their velocity, and scattering is not isotropic. N. M. B.

**Bragg reflexion of slow neutrons.** D. P. MITCHELL and P. N. POWERS (Physical Rev., 1936, [ii], 50, 486—487).—Using large MgO single crystals, data for relative reflexion and scattering indicate that the observed reflexion of slow neutrons is in accord with the Bragg relation between their de Broglie  $\lambda$  and the grating space of the crystals. N. M. B.

**Influence of temperature on the "groups" of slow neutrons.** A. ARSENJEWA-HEIL, O. HEIL, and C. H. WESTCOTT (Nature, 1936, 138, 462).—The radioactivity induced in Ag at 20°, 77°, and 290° abs. by slow neutrons of different energies, the A, B, and C groups of Amaldi and Fermi, has been determined. All three groups are affected by changes in temp. The assumption that the absorption coeff. of B varies inversely as the velocity of the neutrons is erroneous. L. S. T.

**Absorption of neutrons in silver and cadmium.** N. DOBROTIN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 235—236).—The absorption of neutrons in Ag remains practically unchanged with increased thickness of paraffin whereas in Cd there is a steady increase. The region of intense absorption in Ag begins when the velocity of the neutrons is substantially  $>$  in the corresponding region in Cd. W. R. A.

**Absorption of thermal neutrons in silver at low temperatures.** V. FOMIN, F. G. HOUTERMANS, I. V. KURTSCHATOV, A. I. LEIPUNSKI, L. SCHUBNIKOV, and G. SCHTSCHEPKIN (Nature, 1936, 138, 326—327).—Data obtained at 20.4°, 77°, and 290° abs. are discussed in relation to a Maxwellian distribution for the energies of the neutrons. L. S. T.

**Nuclear reactions due to neutrons of 2 m.e.v. energy.** E. T. BOOTH and C. HURST (Nature, 1936, 138, 367—368).—No appreciable activity was observed when Mn, Cr, Al, Zn, Si, Fe, Ni, Ca, and Mg were bombarded for periods varying from 20 min. to 6 hr. by neutrons of approx. 2 m.e.v. energy obtained by bombarding D<sub>2</sub> with D ions. L. S. T.

**Scattering of neutrons by protons.** M. A. TUBE and L. R. HAFSTAD (Physical Rev., 1936, [ii], 50, 490—491).—Corr. measurements for 600—1200 kv. neutrons from C, with precautions to eliminate the effect of any neutrons of energy  $<$ 300 kv., agree with the predictions of Wigner's formula. N. M. B.

**Nuclear chemistry and the scattering of protons in collisions with neutrons.** D. M. GANS and W. D. HARKINS (Physical Rev., 1935, [ii], 47, 795—796). L. S. T.

**Capture and scattering of neutrons.** H. A. BETHE (Physical Rev., 1935, [ii], 47, 640).—Theoretical. L. S. T.

**Scattering of fast neutrons by heavy nuclei.** C. H. FAY (Physical Rev., 1936, [ii], 50, 560—567; cf. Dunning, A., 1935, 1186).—Mathematical. An investigation neglecting polarisation indicates that effects due to this are small. N. M. B.

**Neutron absorption of boron and cadmium at low temperatures.** V. FOMIN, F. G. HOUTERMANS, A. I. LEIPUNSKI, L. B. RUSINOV, and L. V. SCHUBNIKOV (Nature, 1936, 138, 505).—The effect of temp. on the absorption of neutrons in Fermi's group C by B and Cd using the 2.3 min. Ag activity as detector has been measured. The absorption curve of Cd has a selective character. L. S. T.

**Effect of hydrocarbons at low temperatures on slow neutrons.** W. F. LIBBY and E. A. LONG (Physical Rev., 1936, [ii], 50, 575—576).—Ag targets were bombarded with slow neutrons passed through paraffin cylinders or through a thickness of *n*-heptane. Ag activities plotted against temp. for the range 25—300° abs., obtained by the gradual warming of liquid H<sub>2</sub>, support the assumptions that the neutrons are at the temp. of the hydrocarbon, and that the proton capture and Ag capture cross-sections are  $\propto 1/(\text{neutron velocity})$ . N. M. B.

**Bond effect in the action of protons on neutrons.** W. F. LIBBY and E. A. LONG (Physical Rev., 1936, [ii], 50, 577).—The slowing power of protons on slow neutrons was investigated with liquid and solid H<sub>2</sub>, paraffin, and AcOH, using Ag targets (cf. preceding abstract). There is a nearly identical Ag activity whether the Dewar flask is filled with low-temp. H<sub>2</sub> or with a solution of the same proton density at room temp. Results indicate that the neutrons are cooled to a mean temp.  $\sim$  150° abs., and the expected increase in Ag activity is nearly offset by the increase in capture by protons. N. M. B.

**Resonance energy of cadmium for neutron capture.** E. SEGRE and C. T. ZAHN (Physical Rev., 1936, [ii], 50, 577—578).—The results of Powers (cf. *ibid.*, 49, 650) and of Rasetti (cf. this vol., 264) are considered in terms of the Breit-Wigner formula for the cross-section involved. An approx. resonance energy of 0.05<sub>5</sub> volt and a half-width of about the same val. are deduced. N. M. B.

**Resonance levels for absorption of neutrons.** J. ROTBLAT (Nature, 1936, 138, 545).—The ionisation currents due to slow neutrons from Po+Be produced in a B-coated chamber have been measured in absence and presence of absorbers of Cd, Cd+Ag, Au, and I as KI, and the resonance levels of the neutrons calc. L. S. T.

**Names of and symbols for the artificially radioactive elements.** G. M. PETTY (Science, 1936, 84, 183).—The prefix *radio-* and symbol *ra-* are suggested. L. S. T.

**Symbols for the artificially radioactive elements.** S. C. LIND (Science, 1936, 84, 228—229).—Rd is suggested as a prefix for the natural radioactive elements and "rd-" for the artificial ones. L. S. T.

Analysis of the data on radioactivity induced by neutron bombardment. C. N. WARFIELD (Physical Rev., 1935, [ii], 47, 796—797).—Eight generalisations are put forward. L. S. T.

Correlation of nuclear disintegration processes. M. S. LIVINGSTON and R. D. EVANS (Physical Rev., 1935, [ii], 47, 795; cf. this vol., 919).—The known artificial nuclear transformations and natural radioactive processes are classified under one of 14 generalised type reactions. The 200 or more reactions can be represented diagrammatically. L. S. T.

Radio-helium. T. BJERGE (Nature, 1936, 138, 400).—Bombardment of finely-pptd  $\text{Be}(\text{OH})_2$  by neutrons from  $\text{Be}+\text{Rn}$  produces a radioactive gas of half-period approx. 1 sec. in the  $\text{Be}(\text{OH})_2$  (cf. this vol., 773). The gas is  $^3\text{He}$  or possibly  $^4\text{He}$ . L. S. T.

$\beta$ -Ray spectrum of radio-helium. T. BJERGE and K. J. BROSTROM (Nature, 1936, 138, 400).—The energy distribution of radio-He (cf. preceding abstract) has been measured. The upper limit of the spectrum is probably  $3.7 \pm 0.5$  m.e.v. Probable reactions are  $^7\text{Be} + \frac{1}{2}n \rightarrow ^7\text{He} + ^4\text{He}$  and  $^6\text{He} \rightarrow ^3\text{Li} + e^-$ . L. S. T.

Low-voltage disintegration of lithium with lithium. C. A. WHITMER and M. L. POOL (Physical Rev., 1935, [ii], 47, 795).— $\alpha$ -Particles are produced by bombardment of a Li target with multiply-charged Li ions accelerated by a potential of approx. 120 kv.  $\text{LiOH}$  and  $\text{LiOD}$  give a larger yield than pure Li, but a Be target gives no results. L. S. T.

(A) Deuteron-induced radioactivities. J. J. LIVINGOOD. (B) Deuteron-induced radioactivity in tin. J. J. LIVINGOOD and G. SEABORG (Physical Rev., 1936, [ii], 50, 425—434, 435—439).—(A) Bombardment of elements with 5-m.e.v. deuterons gave the following results: commercial Cu decays with half-life  $130 \pm 10$  days, emitting  $\gamma$ -rays and very slow electrons; Zn emits electrons with half-lives  $97 \pm 10$ ,  $25 \pm 2$ ,  $12 \pm 1$ , and  $1 \pm 0.3$  hr., the third being probably due to radio- $^{64}\text{Cu}$ ; Sb gives electron activities with half-lives  $50 \pm 4$  days,  $68 \pm 2$  and  $24 \pm 2$  hr.; corresponding results for Ru are  $46 \pm 3$ ,  $11 \pm 2$  days,  $39 \pm 1$  and  $4 \pm 1$  hr. Bi yields electrons of 5 days half-life and  $\alpha$ -particles increasing in no. to a const. val. after 3 weeks; this is interpreted as the synthesis of Ra-E thus:  $^{209}\text{Bi} + ^2\text{H} \rightarrow ^{210}\text{Bi}$  (i.e.,  $\text{Ra-E} + ^1\text{H}$ ), followed by its decay to Po and thence to Pb.

(B) Sn was bombarded with 5-m.e.v. deuterons and chemically analysed for transmutation into radioactive In, Sn, and Sb isotopes. The In fraction shows strong electron emission of  $26 \pm 2$  hr. half-life and a very weak activity of half-life probably several months. The Sn ppt. emits an intense electron group of half-life  $28 \pm 2$  hr. and a weak activity as for In. Two Sb isotopes are formed with half-lives  $13.3 \pm 1$  hr. and  $112 \pm 30$  days. Short period activities from bombarded Sn are of  $12 \pm 2$  and  $45 \pm 5$  min. half-life. Absorption curves in Al are given and possible transmutations discussed. N. M. B.

Radioactive isotopes of bromine. C. H. JOHNSON and F. T. HAMBLIN (Nature, 1936, 138, 504).—

After exposure to neutrons for 1 week liquid Br gives an activity of approx. 24 hr. half-period. AgBr pptd. from irradiated aq.  $\text{NH}_4\text{Br}$  gives a similar effect. The reactions  $^{79,81}\text{Br} + \frac{1}{2}n \rightarrow ^{79,81}\text{Sc} + ^1\text{H}$  or  $^{76,83}\text{As} + ^4\text{He}$  are excluded. This activity is probably due to another radioactive isotope of Br or to an excited Br nucleus, since it has not been possible to separate it from the 18 min. and 4.2 hr. activities observed by Fermi *et al.* Possible reactions are discussed. L. S. T.

Measurement of single corpuscular rays in presence of intense  $\gamma$ -rays. H. POSE (Z. Physik, 1936, 102, 379—407).—A description is given of apparatus used for the investigation of nuclear transformations brought about with  $\alpha$ -particles. Results obtained with Al are similar to those of Duncanson and Miller (A., 1934, 1284). A. E. M.

Specific ionisation of cosmic radiation. M. G. E. COSYNS (Nature, 1936, 138, 284).—Sp. ionisations of cosmic rays in  $\text{H}_2$ , He, and A are recorded. L. S. T.

Measurements of cosmic ray intensity in a deep [coal] mine. J. BARNÓTHY and M. FORRO (Nature, 1936, 138, 325, 399).—Cosmic rays penetrate a layer equiv. to a thickness of 1500 m. of  $\text{H}_2\text{O}$ , corresponding with particles of an energy  $> 10^{12}$  e.v. L. S. T.

Search for protons in the primary cosmic-ray beam. C. G. MONTGOMERY, D. D. MONTGOMERY, W. E. RAMSEY, and W. F. G. SWANN (Physical Rev., 1936, [ii], 50, 403—407).—Measurements of ionisation spurts above an assigned size are an indication of the presence of charged particles towards the end of their range. Results indicate an upper limit of the no. of protons as 5% of the total no. of cosmic rays at sea level. N. M. B.

Variation of cosmic ray intensity with sidereal time. B. F. J. SCHONLAND, B. DELATIZKY, and J. P. GASKELL (Nature, 1936, 138, 325). L. S. T.

Longitude effect of cosmic radiation. M. S. VALLARTA (Physical Rev., 1935, [ii], 47, 800; cf. A., 1935, 560). L. S. T.

Structure of cosmic rays. II. B. TRUMPY (Z. Physik, 1936, 102, 691—696).—No confirmation is obtained of the results of Hilgert and Botha (cf. this vol., 658) that by passage of cosmic rays through coal photons are formed which produce showers in Pb. O. D. S.

Angular distribution and number of pairs (C-rays) produced by cosmic ultra-radiation in lead. B. PUSCHER (Physikal. Z., 1936, 37, 661—663).—A curve is given showing the angular distribution of C-rays in terms of coincidences per hr. at different angles. The max. occurs at  $7-12^\circ$ . A. J. M.

Production of cosmic ray showers. A. BRAMLEY (Science, 1936, 84, 206—207).—Theoretical. L. S. T.

Absorption analysis of the Hoffmann collisions. J. BOGGILD and A. KARKOV (Naturwiss., 1936, 24, 588—589).—An experiment described indicates that the collisions are accompanied by a soft radiation. A. J. M.

**Dependence of burst production on atomic number.** C. G. MONTGOMERY and D. D. MONTGOMERY (Physical Rev., 1936, [ii], 50, 490; cf. this vol., 133).—Investigation of bursts originating in small thicknesses of Mg, Fe, Sn, and Pb shows that the rate of production of bursts  $\propto$  (at. no.)<sup>2</sup>. Results indicate that the nuclei remain intact under the impact of cosmic rays, and that the building-up process involved in burst formation is not one of pair production. N. M. B.

**Production and absorption of cosmic-ray showers [in lead].** R. H. WOODWARD and J. C. STREET (Physical Rev., 1935, [ii], 47, 800). L. S. T.

**Absence of cosmic rays from Nova Lacertæ.** BARNÓTHY and M. FORRÓ (Nature, 1936, 138, 544—545). L. S. T.

**Interaction of the neutron and proton.** Y. NISHINA, S. TOMONAGA, and H. TAMAKI (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 30, 61—69).—Mathematical. Experimental results are explained on the basis of simultaneous Heisenberg exchange forces and Majorana forces. N. M. B.

**Energy states of valency electrons in some metals. I. (2) Absolute values of some X-ray levels of zinc.** M. SATÔ (Sci. Rep. Tôhoku, 1936, 25, 197—201).—Theoretical. Energy levels calc. for Zn are: *K* term 711.880 Ryd., valency electrons *E*<sub>1</sub> 0.960, *E*<sub>2</sub> 0.840, *E*<sub>3</sub> 0.600, *E*<sub>4</sub> 0.581, *E*<sub>5</sub> 0.545, and *E*<sub>6</sub> 0.021 crystal Ryd. units. O. D. S.

**Coulomb energy of <sup>3</sup>He.** S. S. SHARE (Physical Rev., 1936, [ii], 50, 488—489).—Mathematical. The difference in binding energies of <sup>3</sup>H and <sup>3</sup>He is approx. equal to the calc. Coulomb, energy, supporting the view that, except for the Coulomb repulsion between protons, the neutron-neutron and proton-proton attractions are equal. N. M. B.

**Electric quadrupole moment of the nucleus <sup>123</sup>I.** (A) T. SCHMIDT. (B) S. TOLANSKY (Nature, 1936, 138, 404—405, 405).—(A) The <sup>123</sup>I nucleus has a negative electric quadrupole moment  $< -0.5 \times 10^{-24}$ , the negative sign indicating that the charge distribution is flattened in the direction of the spin axis.

(B) The moment suggested can only be considered tentative. L. S. T.

**Nuclear states and moments.** D. R. INGLIS (Physical Rev., 1935, [ii], 47, 813; cf. A., 1935, 278).—A discussion. L. S. T.

**Relation between hyperfine structure and atomic nuclei.** H. SCHULER and H. KORSCHING (Z. Physik, 1936, 102, 373—378).—Certain rules for the building up of at. nuclei are formulated from a consideration of hyperfine structure data. The relative abundance of isotopes of all elements for which the data are available conforms to these rules.

H. C. G.

**Dependence of nuclear forces on spin.** C. F. VON WEINSACKER (Z. Physik, 1936, 102, 572—602).—Mathematical. The dependence of nuclear forces on the spin orientation of protons and neutrons is investigated. O. D. S.

**Magnetic moment of the proton.** H. HONL (Naturwiss., 1936, 24, 637—638).—Theoretical. It is shown that the magnetic moment of the proton is about 3 nuclear magnetons (1 nuclear magneton = 1 Bohr magneton/1840). A. J. M.

**Gyromagnetic properties of the hydrogens.** J. M. B. KELLOGG, I. I. RABI, and J. R. ZACHARIAS (Physical Rev., 1936, [ii], 50, 472—481).—The nuclear moments of the proton and deuteron were measured by the method of at. beams, independently of at. velocity distribution, and the signs of the moments by the method of non-adiabatic transitions in a weak magnetic field. Results are:  $\mu_H$  2.85 ± 0.15;  $\mu_D$  0.85 ± 0.03 nuclear magnetons; signs of both moments are positive. N. M. B.

**Conservation of energy in radiation processes.** E. J. WILLIAMS and E. PICKUP (Nature, 1936, 138, 461—462).—Further experiments on the production of photo-electrons in A by X-rays confirm the light-quantum theory and the applicability of conservation principles to X-radiation processes (cf. this vol., 660). L. S. T.

**Energy levels of light nuclei.** G. BECK (Physical Rev., 1935, [ii], 47, 809—810).—Theoretical. L. S. T.

**Nature of energy states in solids.** F. H. SPEDDING (Physical Rev., 1936, [ii], 50, 574).—In view of discrepancies arising from the application of the theory for the behaviour of energy levels of an atom subjected to the electric fields of other atoms in a cryst. solid, as developed by Penny (cf. A., 1932, 985) and Frank (cf. this vol., 19), results of a spectroscopic study of the energy levels of Nd, Sm, Er, and Dy are reported. Energy level separations as found from absorption spectra are compared with those predicted by theory. N. M. B.

**Interaction of heavy nuclear particles.** D. IVANENKO and A. SOKOLOV (Nature, 1936, 138, 246).—Theoretical. L. S. T.

**Correlation between electromagnetic theory and wave mechanics.** L. T. DEVORE (Physical Rev., 1935, [ii], 47, 638). L. S. T.

**Approximate determination of the atomic wave functions of chromium.** A. PORTER (Mem. Manchester Phil. Soc., 1934—1935, 79, 75—81).—Calculations for Cr and Cr<sup>++</sup> have been made using the differential analyser. R. S. B.

**Validity of X-ray crystal methods of determining *e*.** J. W. M. DUMOND and V. L. BOLLMAN (Physical Rev., 1936, [ii], 50, 524—537).—Measurements with extremely finely powdered calcite give conclusive evidence in favour of the X-ray crystal method. The val. of *e* is 4.799 ± 0.007. Several new unexplained crystal diffraction effects are described.

N. M. B.

**Application of the Franck-Condon principle to continuous absorption spectra of diatomic molecules.** H. TRIVEDI (Proc. Acad. Sci. U.P., 1935, 4, 59—70).—Theoretical. CH. ABS. (e)

**Determination of the atmospheric transparency coefficients for different spectral rays and the density of atmospheric ozone.** N. P.

LUGIN (J. Geophys. U.S.S.R., 1935, 5, 58—76).—Transparency data and vals. for the  $[O_3]$  are given.

CH. ABS. (e)

**Isotopes and molecular asymmetry.** T. IRDALE (Nature, 1936, 138, 292).—It is suggested that asymmetric mols. containing Me and F should be examined for optical resolution.

L. S. T.

**Absorption spectrum of hydrogen peroxide vapour.** R. S. SHARMA (Proc. Acad. Sci. U.P., 1934, 4, 51—58).—The ultra-violet absorption spectrum of 3, 10, and 30% aq.  $H_2O_2$  terminates abruptly at 2055 Å., corresponding with  $H_2O_2 + 136.1$  kg.-cal. =  $2H + O_2$ . The recombination spectrum corresponds with  $H + HOO - H_2O_2 + 59.6$  kg.-cal. CuO in the absorption tube became reddish, showing the presence of at. H.

CH. ABS. (e)

**Spectroscopic investigation of chemical reactions of OH in the electric discharge.** A. A. FROST and O. OLDENBERG (Physical Rev., 1935, [ii], 47, 788).—OH produced by the electric discharge through  $H_2O$  vapour has a lifetime of the order of  $\lambda$  sec. The chief process by which OH disappears is indicated to be the three-body process  $OH + OH + M \rightarrow H_2O_2 + M$ .

L. S. T.

**Ultra-violet absorption spectra of the deutero-ammonias.** W. S. BENEDICT (Physical Rev., 1935, [ii], 47, 641).—Spectrograms of  $NH_3$  containing varying amounts of D have been obtained over a wide range of temp. and pressure. Vibrational analyses have been made for  $NH_3$ ,  $NH_2D$ ,  $NHD_2$ , and  $ND_3$ .

L. S. T.

**Band system of copper deuteride.** M. A. JEPPESEN (Physical Rev., 1936, [ii], 50, 445—449).—Full data and analysis of the system photographed at high dispersion are tabulated and constns. are evaluated. The electronic isotope displacement of CuD relative to CuH is  $19\text{ cm}^{-1}$ .

N. M. B.

**Pressure effect on the C band of strontium hydride.** R. F. HUMPHREYS and W. R. FREDRICKSON (Physical Rev., 1936, [ii], 50, 542—545; cf. A., 1935, 1443).—At low  $H_2$  pressures the emission spectrum of the 3808 Å. band of SrH shows a sharp break-off at  $R(18)$ , but at high pressures the lines extend to  $R(49)$ . Perturbations due to resonance and predissociation are present. Frequency assignments are tabulated, and electronic configurations and probable dissociation energies are discussed.

N. M. B.

**Band spectrum of silicon fluoride.** R. M. BADGER and C. M. BLAIR, jun. (Physical Rev., 1935, [ii], 47, 881).—A re-examination of the violet spectrum obtained in the Si fluoride discharge reveals two systems with considerable overlapping. Previous conclusions (A., 1927, 1005) are invalidated. The emitter is probably SiF.

L. S. T.

**Absorption spectra of the vapours of sulphur monochloride and thionyl chloride and their constitutions.** H. TRIVEDI (Proc. Acad. Sci. U.P., 1935, 4, 263—268).—The ultra-violet absorption spectra of both  $S_2Cl_2$  and  $SOCl_2$  show two bands at 2740, 2135 and 2980, 2040 Å., respectively. The differences in energy between the beginnings of the

bands correspond with that between the 3P and 1D states of S (for  $S_2Cl_2$ ) and of O (for  $SOCl_2$ ). The structures are  $S:S:Cl_2$  and  $O:S:Cl_2$ .

CH. ABS. (e)

**Band system of TiCl.** A. E. PARKER and A. H. PARKER (Physical Rev., 1935, [ii], 47, 812).—The four-headed band system extending from 4340 to 3730 Å. has been analysed.

L. S. T.

**Band spectrum of arsenic oxide and lead oxide.** E. N. SHAWHAN and F. MORGAN (Physical Rev., 1935, [ii], 47, 199; cf. A., 1935, 562).—The band spectrum of AsO has been investigated in emission and in absorption. Two systems of double double-headed bands have been analysed.

L. S. T.

**Far ultra-violet absorption spectra and ionisation potentials of the alkyl halides.** I. [Methyl halides.] II. [Ethyl and higher halides.] W. C. PRICE (J. Chem. Physics, 1936, 4, 539—547, 547—551).—I. The absorption spectra of MeI, MeBr, and MeCl have been photographed in the region 2000—1000 Å. The bands are due to excitation of non-binding electrons in the halogen atoms, and the ionisation potentials deduced from the Rydberg series are: MeI 9.49 and 10.11 volts, MeBr 10.49 and 10.80, and MeCl 11.17 and 11.25, in general accord with theory (cf. A., 1935, 562). The vibrational nature of the bands is discussed and the three spectra are correlated.

II. The Rydberg series found in the range 2000—1000 Å. lead to the ionisation potentials EtI 9.30 and 9.88, and EtBr 10.24 and 10.56 volts. Other halides gave very diffuse bands, and continuous absorption from C-C and C-H linkings interfered. The ionisation potentials of consecutive members of the homologous series probably diminish asymptotically to a limiting val.

J. G. A. G.

**Mutual optical effect of neighbouring colour carriers in a molecule.** H. FROMHERZ, W. AUMULLER, and C. O. STROTHER (Z. Elektrochem., 1936, 42, 680).—For dihalogenated paraffins with at least one  $CH_2$  between the halogen (Br or I) atoms, the light absorption is const. and equal to the sum of the absorptions of the individual groups. When the halogen atoms are nearer, and especially when they are the same, the absorption band shifts towards longer  $\lambda$ . This effect is increased when the H near the halogens is replaced by alkyl.

J. W. S.

**Light absorption and tautomerism of uric acid.** H. FROMHERZ and A. HARTMANN (Z. Elektrochem., 1936, 42, 687).—The absorption spectrum of uric acid has been measured in pure  $H_2O$  and in presence of excess of  $HClO_4$  and of NaOH, comparison being made with the absorption spectra of substituted uric acids of definite keto- and enol forms. The results indicate that in  $H_2O$  or acid, uric acid is in the keto-form, but addition of a little NaOH shifts the absorption bands towards longer  $\lambda$ , corresponding with the enol form. This is a halochromatic effect due to dissociation of a H atom, and is compared with the change in absorption between dissociated and undissociated  $CO_2H$  groups.

J. S.

**Influence of substituents on the ultra-violet absorption spectra of simple and double-linking**

conjugated benzene chromophores. M. PESTEMER, T. LANGER, and F. MANCHEN (Monatsh., 1936, 68, 326—348).—The absorption spectra of  $\text{BzCl}$ ,  $\text{CHPhCl}_2$ ,  $\text{CPhCl}_3$ , styrene,  $\text{COPhMe}$ , and  $\text{PhCHO}$  and of their  $\text{NH}_2$ -,  $\text{CN}$ -, and  $\text{NO}_2$ -substitution products have been studied in the region 25,000—50,000  $\text{cm}^{-1}$ , and compared with those of  $\text{C}_6\text{H}_6$  and  $\text{PhMe}$  compounds. The effect of the substituents on both the *A* (38,500—43,400  $\text{cm}^{-1}$ ) and *B* (49,000—52,000  $\text{cm}^{-1}$ ) bands of the conjugated systems  $\text{Ph}\cdot\text{C}\cdot\text{C}$  and  $\text{Ph}\cdot\text{C}\cdot\text{O}$  is to shift them towards longer  $\lambda$ , the effects being in the order  $p > m > o$ . This is the same order as the effect of substituents on the *B* band for  $\text{PhMe}$ , but the reverse of that for the *A* band. The relative effects of the  $\text{NH}_2$ - and of the  $\text{NO}_2$ - and  $\text{CN}$ -groups are in accord with their respective negative and positive characters. J. W. S.

**Absorption spectra of anils of aliphatic ketones. Absorption in the ultra-violet and structure of anils and  $\alpha$ -ethylenic amines.**—See this vol., 1242.

**Optical absorption of the porphyrins. VII.** A. STERN and H. WENDERLEIN (Z. physikal. Chem., 1936, 177, 165—192; cf. this vol., 1178).—Introduction of vinyl groups into the dihydroporphyrin system (I) shifts the absorption max. towards the red and at times intensifies them, but does not alter the type of the absorption curve.  $\gamma$ -Substitution with weak chromophoric groups has little effect. Introduction of a CO at 3 causes the curve to change to the "rhodin" type, band I of the spectrum being depressed and shifted towards the blue. Oximation raises band I and shifts it towards the red. CO at 6 does not give rise to the rhodin type of curve. It is inferred that nucleus III differs in structure from nuclei I and II, and has no double linking at 5:6, and that in this nucleus are located the optically active centres of the system (cf. A., 1935, 1383). Chlorin  $p_6$  and pseudochlorin  $p_6$  have different absorption curves and are in some way stereoisomeric. The purpurins and rhodins seem to have the (I) framework. Mg in (I) only displaces the fluorescence bands towards the red. R. C.

**Ultra-violet absorption spectra of thyroxine, thyronine, tyrosine, di-iodotyrosine, and thyroglobulin.**—See this vol., 1249.

**Gossypol.** R. GRÜNBAUMÓWNA and L. MARCHLEWSKI (Biochem. Z., 1936, 286, 295—296).—An absorption curve of gossypol acetate showing max. at 3780 and 2390 Å. and a min. at 3220 Å. is given. P. W. C.

**Nuclear vibration bands of solid carbon dioxide.** W. DAHLKE (Z. Physik, 1936, 102, 360—372).—Apparatus for determining the absorption of thin layers of solid  $\text{CO}_2$  at about 100° abs., throughout the spectrum from the visible to 17  $\mu$  is described. Three absorption bands are obtained similar to the rotation-vibration bands found in the gas. The possibility of mol. rotation in solid  $\text{CO}_2$  is discussed. A. E. M.

**2.73  $\mu$  Absorption band in fused silica.** D. G. DRUMMOND (Nature, 1936, 138, 248—249).—The view that this band is due to  $\text{CO}_2$  contamination is favoured (cf. this vol., 921). L. S. T.

**Diffuse infra-red transmission of solids.** J. D. HARDY and C. MUSCHENHEIM (Physical Rev., 1935, [ii], 47, 789). L. S. T.

**Fundamental absorption bands of the deutero-ammonias.** M. V. MIGOTTE and E. F. BARKER (Physical Rev., 1936, [ii], 50, 418—424; cf. *ibid.*, 1935, [ii], 47, 892).—The four fundamental vibration bands of  $\text{ND}_3$  were observed in infra-red absorption,  $\nu_3$  being double as in  $\text{NH}_3$ ; the parallel frequencies are:  $\nu_1 = 2420$ ,  $\nu_3 = 749.2$  and  $745.8$ , the perpendicular are:  $\nu_2 = 2556$ ,  $\nu_4 = 1191.3$   $\text{cm}^{-1}$ . The rotational structure of  $\nu_3$  is completely resolved. The moments of inertia of  $\text{ND}_3$  are:  $C = 8.985 \times 10^{-40}$  with respect to the symmetry axis, and  $A = 5.397 \times 10^{-40}$  g.  $\text{cm}^2$  for any perpendicular axis. The height of the mol. pyramid is  $0.360 \times 10^{-8}$ , and distance between D atoms  $1.645 \times 10^{-8}$  cm. The potential curve is discussed. N. M. B.

**Vibrational levels of cyclopropane.** G. W. KING, R. T. ARMSTRONG, and L. HARRIS (J. Amer. Chem. Soc., 1936, 58, 1580—1584).—The infra-red absorption and Raman spectra have been determined, and the results are discussed. E. S. H.

**Absorption spectrum of heavy methane ( $\text{MeD}$ ) in the photographic infra-red.** W. H. J. CHILDS and H. A. JAHN (Nature, 1936, 138, 285).—The absorption spectrum of  $\text{MeD}$  from 12,000 to 6000 Å. shows none of the lines of  $\text{CH}_4$ . A region of intense absorption extends from 8350 to 9000  $\text{cm}^{-1}$  with a strong, broad max. at 8617  $\text{cm}^{-1}$ . Similarities with the spectrum of  $\text{CH}_4$  are pointed out. L. S. T.

**Infra-red absorption spectra of acetic acid and acetic anhydride.** E. K. PLYLER and E. S. BARR (Physical Rev., 1935, [ii], 47, 793; cf. this vol., 34). L. S. T.

**Raman effect. LX. Polarisation measurements. 1. Experimental method.** A. W. REITZ (Z. physikal. Chem., 1936, B, 33, 368—386).—The sources of error in polarisation measurements are discussed, and suitable apparatus and the experimental technique described. R. C.

**Raman spectra and the latent heat of fusion of non-associated substances.** C. J. PHILLIPS (Physical Rev., 1935, [ii], 47, 792).—When applied to 38 org. and inorg. substances in the cryst. and liquid states, the relation  $\lambda = mNh_c/JML_f$ , when  $m$  is 1, 2, . . . and  $L_f$  is the latent heat of fusion, gives  $\lambda\lambda$  which agree closely with the observed infra-red absorption bands. The relation apparently holds only for non-associated substances. In glass the  $\text{SiO}_2$  group may vibrate independently to a certain extent. L. S. T.

**Raman spectrum of thiophosphoryl chloride.** V. N. THATTE (Nature, 1936, 138, 468—469).—Prominent shifts in the Raman spectra of  $\text{POCl}_3$  and  $\text{PSCl}_3$  are compared. The slight reduction in the vals. for the latter is attributed to substitution of O by S. L. S. T.

**Raman effect in solutions of magnesium sulphate of varying concentrations.** E. M. COON and E. R. LAIRD (Physical Rev., 1935, [ii], 47, 889).—Any change in frequency due to concn. ( $N$  to  $4.5N$ ) is  $\lambda > 1$  or 2 wave nos. L. S. T.

**Raman effect and molecular structure.** L. SIMONS (Finska Kem. Medd., 1936, 45, 77—97).—A review, with special reference to  $C_6H_6$ .

M. H. M. A.

**Raman spectrum of deuterioethanol.** S. MIZUSHIMA, Y. MORINO, and G. OKAMOTO (Bull. Chem. Soc. Japan, 1936, 11, 553).—Raman lines closely corresponding with those of EtOH have been observed. The band  $3370 \pm 80$   $cm^{-1}$ , attributed to the -OH linking, is displaced to  $2510 \pm 50$   $cm^{-1}$  in EtOD.

R. S.

**Raman effect of heterocyclic compounds of the dioxan type.** L. MÉDARD (J. Chim. phys., 1936, 33, 626—630; cf. A., 1934, 1289).—The Raman spectra of dioxan (I), dichlorodioxan, thioxan (II), dithian (III), and morpholine have been determined. The vibration frequency of  $CH_2$  is determined by linking to O or S since the  $CH_2$  line 1415 of (III) and the corresponding lines 1445—1460 of (I) appear at 1415—1452 in (II). Lines attributable to the cyclic structure are absent, in agreement with the aliphatic properties of the compounds.

R. S.

**Modification of the Raman spectrum of dioxan by dissolved materials.** A. SIMON and F. FÉHÉR (Z. Elektrochem., 1936, 42, 688—691).—Polar solutes modify the Raman spectrum of dioxan, the CO-frequencies being diminished and the CH-frequencies raised. The changes are due to electrostatic effects and not to formation of mol. compounds. The shape of the solute mol. and the type and location of its dipole have a greater influence than the magnitude of the dipole moment or the deformability of the mol. The results are discussed with reference to Raman frequencies in complicated mols. and in binary mixtures.

J. W. S.

**Raman spectra and the structure of benzene.** G. DUPONT and R. DULOU, with (in part) V. DESREUX (Bull. Soc. chim., 1936, [v], 3, 1639—1661).—The principal Raman frequencies and their relative intensities are tabulated for *cyclo*-hexane and -hexene,  $C_6H_6$ , PhMe, PhEt, PhPr, *o*-, *m*-, and *p*-xylene, *m*-, *p*-, and *o*-cymene,  $\psi$ -cymene, mesitylene, thiophen, *alloo*cimene, PhOH,  $NH_2Ph$ ,  $p$ - $C_6H_4EtOMe$ ,  $p$ - $C_6H_4PrOMe$ , eugenol, *isoeugenol*, dihydroeugenol, saffrole, *isosaffrole*, and dihydrosaffrole. It is concluded that in  $C_6H_6$  a form predominates which may be represented by a formula of hexagonal symmetry, e.g., the Stark-Pauli formula, and is responsible for the aromatic properties, but a second form, corresponding with Kekulé's formula, is also present in small quantities.

J. W. S.

**Raman spectrum of heavy benzene  $C_6D_6$ .** R. W. WOOD (Physical Rev., 1935, [ii], 48, 488; cf. A., 1935, 1189).

L. S. T.

**Raman spectra and vibrations of di- and tetra-deutero benzene.** O. REDLICH and W. STRICKS (Monatsh., 1936, 68, 374—382; cf. this vol., 663, 922).—The Raman spectra of *o*- and *m*- $C_6H_4D_2$  and of a mixture of the  $C_6H_2D_4$  isomerides have been determined. The frequencies calc. from the valency energy model of  $C_6H_6$  differ considerably from the observed frequencies, but a generalised model is developed which is in satisfactory accord for  $C_6H_6$ ,

$p$ - $C_6H_4D_2$ , 1:2:4:5- $C_6H_2D_4$ , and  $C_6D_6$ . The Ca salt of polycarboxylic acids of  $C_6H_6$  when heated with  $Ca(OH)_2$ , yields only a mixture of isomerides.

J. W. S.

**Raman spectrum of hydroxyquinol trimethyl ether.** S. FRIED and B. SUSZ (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 124—126; cf. Kohlrausch, A., 1935, 146).—Raman data for 1:2:4- $C_6H_3(OMe)_3$  are reported.

N. M. B.

**Raman spectra of *cis*- and *trans*-isoeugenol.** E. PERROTET and B. SUSZ (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 120—124; cf. this vol., 923).—Raman frequencies for the pure commercial substance (80% *trans*, 20% *cis*) and for the two isomerides are tabulated. *iso*Eugenol contains all the frequencies of these two forms with the exception of 1629  $cm^{-1}$ . The vals. for *trans* show an approx. const. difference from those for *cis*, the former being the higher.

N. M. B.

**Raman effect. LVIII. Raman spectra of organic substances. Nitrogen compounds. I. Simple amines.** K. W. F. KOHLRAUSCH. LIX. Raman spectra of organic substances. Nitrogen compounds. II. Amino- and hydroxy-acetic acids and esters. L. KAHOVEC and K. W. F. KOHLRAUSCH (Monatsh., 1936, 68, 349—358, 359—373).—LVIII. The Raman spectra of  $NH_2Me$ ,  $NH_2Et$ ,  $NH_2Pr^a$ ,  $NHMe_2$ , and  $NMe_3$  have been determined and compared with those of  $Me_2O$ ,  $Me_2S$ , and  $MeOEt$ .

LIX. The Raman spectra of  $NH_2 \cdot CH_2 \cdot CO_2H$  and its Me, Et,  $Pr^a$ , and  $Bu^a$  esters,  $(NH_2)_2CH \cdot CO_2H$  and its Me and Et esters,  $OH \cdot CH_2 \cdot CO_2H$  and its Me, Et,  $Pr^a$ , and  $Bu^a$  esters,  $NH_2 \cdot CH(OH) \cdot CO_2H$  and its Me and Et esters,  $EtCO_2H$  and its  $Pr^a$  and  $Bu^a$  esters,  $CH_2Cl \cdot CO_2H$ , and  $CH_2Br \cdot CO_2H$  have been determined in the solid state and/or in aq. solution.

J. W. S.

**Raman spectrum of piperidine.** S. M. MITRA (Z. Physik, 1936, 102, 697—699).—A new line at  $\Delta\nu=1451$  is observed in this spectrum.

O. D. S.

**Excitation of Raman spectra of substances with the aid of "optical catalysers."** K. PRASAD and D. K. BHATTACHARYA (Nature, 1936, 138, 510—511).—The method used for glass (this vol., 270) has been extended to  $H_2O$ , MeOH, EtOH,  $COMe_2$ ,  $C_5H_5N$ , and aq.  $HNO_3$ , traces of  $KMnO_4$  being added to produce absorption bands in these media. The importance of the new technique for the study of Raman spectra is discussed.

L. S. T.

**Raman spectra of gallic acid, of its derivatives, and of tannin.** B. SUSZ and S. FRIED (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 69—74; cf. A., 1935, 1446).—Raman data are recorded and discussed for pyrogallol, gallic acid, Me gallate, Me trimethylgallate, triacetyl gallic acid, and tannin.

N. M. B.

**Induced ultra-violet fluorescence and its release by visible light.** O. GLASSER and I. E. BEASLEY (Physical Rev., 1935, [ii], 47, 570).—The ultra-violet fluorescence of certain substances following exposure to X- or  $\gamma$ -radiation is found to persist for unexpectedly long periods of time. It is markedly increased when the irradiated compounds are exposed to visible light. Of the 25 substances examined, NaCl, KCl, rock-salt, and fluorite crystals showed

these effects most clearly. Impurities inhibit the subsequent induction of the fluorescence. L. S. T.

**Scintillations of zinc sulphides in  $\alpha$ -rays.** G. DESTRIAU (J. Chim. phys., 1936, 33, 587—625; cf. A., 1931, 1108).—ZnS screens free from Canada balsam have been prepared from a suspension of ZnS in EtOH. Using a Po source, it has been shown that the no. of scintillations—distance curve varies with the specimen of ZnS. For a given specimen, the curvature is the sharper the smaller is the ZnS crystal and the richer the crystal in phosphorogen. Whilst the concn. of phosphorogen runs parallel to the [Cu], there is no direct proportionality, and only a part of the Cu appears to be active. Theoretical curves in agreement with the experimental results have been derived and the influence of crystal size, concn. of phosphorogen, and the no. of centres excited by an  $\alpha$ -particle have been investigated. The view that scintillations involving only one active centre are visible is discussed in relation to data on the min. of visual perception. The mean duration of the scintillations, determined microscopically by a rotating-disc method, increases with the concn. of active phosphorogen and is a max. in crystals of approx. 27  $\mu$ , but there is no relation between the sensitivity to  $\alpha$ -rays and phosphorescent power of ZnS. The effect of infra-red light, and the relation between the sensitivity to  $\alpha$ -rays, X-rays, and triboluminescence, are discussed. Only one specimen of ZnS showed luminescence in the electric field. R. S.

**Fluorescence of the salts of tervalent europium in aqueous solutions.** J. LARIONOV and A. SEIDEL (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 115—118).—Fluorescence spectrum data are given. Three narrow bands in the red occur only with solutions containing  $\text{SO}_4^{2-}$ , and are ascribed to  $\text{Eu}^{+++}$ . One narrow band and two broad bands in the blue-ultra-violet region are of general occurrence: the latter coincide with bands observed in solutions of Ce and Y earth salts. A. J. E. W.

**Effect of visible light on the ultra-violet fluorescence of various compounds previously irradiated with Röntgen or  $\gamma$ -rays.** O. GLASSER and I. E. BEASLEY (Physical Rev., 1935, [ii], 47, 789).—The ultra-violet fluorescence of NaCl, KCl, NaBr, rock-salt, and fluorite crystals following exposure to X- or  $\gamma$ -radiation is markedly increased by exposure to visible light. With NaCl the emitted radiation has a max. near 2450 Å. L. S. T.

**Luminescence of calcite. I. Fluorescence spectrum of Japanese calcite in ultra-violet light.** E. IWASE and T. KURONUMA. II. Thermoluminescence. III. Alteration of the fluorescence spectrum by previous heating. E. IWASE (Bull. Chem. Soc. Japan, 1936, 11, 513—522, 523—528, 528—538).—I. All specimens did not fluoresce but band max. were observed at 625—635, 460—470, 515—520, and 560—570 m $\mu$ . Calcites from mineral veins gave a reddish-orange fluorescence, whilst stalactitic calcites gave a whitish fluorescence.

II. A no. of thermoluminescence bands have been determined, but no relation between thermoluminescence and fluorescence could be obtained.

III. The fluorescence of white-fluorescing calcites is affected by previous heating, whilst that of the orange-red type is not. Bands in the Arakawa calcite can be attributed to the presence of rare-earth metals. R. S.

**Fluorescence of chlorophyll in its relation to photochemical processes in plants and organic solutions.** J. FRANCK and R. W. WOOD (J. Chem. Physics, 1936, 4, 551—560; cf. A., 1935, 681).—Chlorophyll, illuminated in org. solutions, behaves as though excited chlorophyll,  $\text{HChph}^*$ , which is free from adsorbed mols., has a small probability of fluorescing and a greater probability of pre-dissociating into a H and monodehydrochlorophyll. The products of dissociation react with any  $\text{O}_2$  present unless  $\text{O}_2$ -acceptors, RH, are also present which take up the excitation energy by collision of the second kind or by intramol. energy exchange within a complex  $\text{HChphRH}$  (I) and protect  $\text{HChph}$  (II) against oxidation, whilst the RH is oxidised after initial formation of H and R or  $\text{HChphR}$  (III). The change of intensity of the fluorescence with period of illumination in presence of  $\text{O}_2$  and certain acceptors is interpreted in terms of the inferred properties of the complexes (III) and (I). The fluorescence of (III) is  $>$  that of (I). Determinations of the similar variations in the intensity of fluorescence with time of illumination of living leaves in presence of  $\text{O}_2$  (cf. A., 1935, 1038) are consistent with photosynthesis and photo-oxidation of org. substances adsorbed to (II) taking place in the plant, but (II) is not itself photo-oxidised. The "light saturation" of photosynthesis *in vivo* may arise from photo-oxidation. The time of half life of (III) is approx. 0.02 sec.

J. G. A. G.

**Emission of aromatic compounds containing the carbonyl group.** N. PRILESHAeva (Acta Physicochim. U.R.S.S., 1935, 3, 195—201).—In the fluorescence of PhCHO and CPhMe vapours the excitation is primarily localised in the  $\text{C}_6\text{H}_6$  ring, whereas the subsequent emission is localised in the CO group. O. J. W.

**Biologically active radiation. III. Supposed photographic detection of earth rays according to Dobler.** B. ROMEIS, J. WÜST, and J. WIMMER (Strahlenther., 1935, 54, 114; Chem. Zentr., 1935, ii, 3745).—No satisfactory evidence of the photographic action of "earth rays," or of their being electromagnetic radiation of about 1 mm.  $\lambda$ , has been brought forward by Dobler. J. S. A.

**Photo-electric threshold of uranium, calcium, and thorium treated with limited amounts of oxygen.** H. C. RENTSCHLER and D. E. HENRY (Physical Rev., 1935, [ii], 47, 807).—A shift in the photo-electric threshold towards the longer  $\lambda$  occurs when surfaces of Th, U, or Ca react with a small amount of  $\text{O}_2$ . L. S. T.

**Photo-electric primary current in an alternating field in potassium bromide crystals containing colour centres.** A. NAUMANN (Ann. Physik, [v], 27, 233—242).—The photo-electric conductivity of crystals of KBr containing electrically formed colour centres has been measured for alternating

currents of frequency between  $10^2$  and  $10^5$  sec.<sup>-1</sup> Ohm's law is obeyed. The conductivity increases with frequency to a saturation val. The ratio conductivity/light absorbed is of the same order of magnitude for the saturation conductivity and for the static conductivity determined at much lower light intensity. It is deduced that the mobility of the photochemically produced electrons is not reduced by the block structure of the crystal. O. D. S.

**Analysis of photo-electric data.** R. J. CASHMAN and N. C. JAMISON (Physical Rev., 1936, [ii], 50, 568—569; cf. Fowler, A., 1931, 1106).—The comparative results of plotting photo-electric current per quantum of light absorbed or per unit intensity of incident radiation are examined. N. M. B.

**Correlation of secondary electron emission with photo-sensitivity and the thermionic effect.** A. DOBROJUBSKI (Z. Physik, 1936, 102, 626—628).—Photocell layers Cs—Cs<sub>2</sub>O—Ag, Ag<sub>2</sub>O—Ag, and Cs—Ag<sub>2</sub>O—Ag were considered. O. D. S.

**Nature of the barrier plane in the cuprous oxide photovoltaic cell.** J. W. BALLARD and E. D. WILSON (Physical Rev., 1935, [ii], 47, 794). L. S. T.

**Colouring and luminescence of crystals under the influence of Becquerel rays.** K. PRZIBRAM (Z. Physik, 1936, 102, 331—352).—A general review of modern work on the colour and luminescence of crystals produced naturally or artificially by pressure or by radioactive emission. Attention is given to the fluorites, alkali halides, and bivalent rare earths. H. C. G.

**Electrical observations during the formation and re-formation of colour centres in potassium bromide and chloride crystals.** G. GLASER (Ann. Physik, 1936, [v], 27, 217—232).—Measurements have been made of the spectral distribution of the photo-electric current in sensitised crystals of KBr and KCl during the photochemical formation of colour centres. No correlation was found between this and the absorption spectrum associated with the *U*-centres. It was correlated with the absorption spectrum of the "X-centres," which underlies that of the *U*-centres, and is similar in form to that of the pure crystal. It is deduced that the photo-electric current is a secondary effect due to the illumination of X-centres, which probably result from foreign mols. in the crystal. O. D. S.

**Ionisation of liquids by X-rays.** L. S. TAYLOR and F. L. MOHLER (Physical Rev., 1935, [ii], 47, 805).—An extension of previous work (A., 1935, 148) to CS<sub>2</sub>, ligroin, tetrahydronaphthalene, and their mixtures. L. S. T.

**Structure of electrolytic oxide films.** H. BETZ (Z. Physik, 1936, 102, 548).—The breakdown potential of Ta<sub>2</sub>O<sub>5</sub> films determined by Rummel (this vol., 923) is the val. obtained by Just (A., 1933, 555). A. J. M.

**Structure of electrolytic oxide films.** T. RUMMEL (Z. Physik, 1936, 102, 549).—A reply to Betz (preceding abstract). A. J. M.

**Measurement of low conductivities and dipole losses with long waves.** C. SCHROECK (Ann. Physik, 1935, [v], 27, 261—284).—A method is described by which conductivities of the order of  $10^{-13}$  ohm<sup>-1</sup> cm.<sup>-1</sup> and dipole losses in liquids can be measured at  $\lambda$  from 170 to 18,000 m. The dielectric const. is determined simultaneously. Data are given of the dipole losses in this region of PrOH, BuOH, and amyl alcohol, glycerol, and aq. solutions of sucrose and fructose. The dielectric const. of mixtures of EtOH and C<sub>6</sub>H<sub>6</sub> is determined and the mol. polarisation of EtOH calc. O. D. S.

**Electric properties of crystals. I, II.** (SIR) W. BRAGG (Proc. Roy. Inst., 1936, 29, 225—230, 290—295).—Lectures.

**Reactivity in solid state at ordinary temperature. II.** A. SERRA (Period. Min., 1935, 6, 179—183; Chem. Zentr., 1935, ii, 3743; cf. A., 1935, 716).—The electrical conductivity of Cu, Fe, Ag, Ni, and Pb wires was increased by contact with finely powdered realgar, Sb glance, Cu glance, haverite, marcasite, and pyrolusite. Sb glance in contact with Ag foil produces a stain of Ag<sub>2</sub>S. J. S. A.

**Influence of electric moment on the number of molecules of base fixed by a salt.**—See this vol., 1241.

**Theory of dielectric polarisation.** J. G. KIRKWOOD (J. Chem. Physics, 1936, 4, 592—601).—A mol. treatment of the polarisation of a non-polar dielectric in a homogeneous field shows that small but significant deviations from the Clausius-Mosotti formula are to be expected. The magnitudes of the corrections are discussed. J. G. A. G.

**Dielectric constant for pure liquid and solid substances. I.** K. HØJENDAHL (Kem. Maanedssbl. nord. Handelsbl. kem. Ind., 1935, 16, 53—55; Chem. Zentr., 1935, ii, 3748).—Vals. are recorded for C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub>. J. S. A.

**Peculiarities of dielectric constant versus pressure curves for vapours.** J. D. STRANATHAN (Physical Rev., 1935, [ii], 47, 794).—For H<sub>2</sub>O vapour deviation of the  $(\epsilon-1)/(\epsilon+2)$ -pressure curve from linearity is due not to conductivity but to adsorption on the insulator surfaces and the consequent increase in polarisation contributed by these additional mols. L. S. T.

**Polar properties of 1:4- and 1:2-dihydronaphthalene.** Polar character of the tetralin molecule. M. PUCHALIK (Acta phys. polon., 1934, 3, 179—185; Chem. Zentr., 1935, ii, 3370).—The dipole moment of 1:4- and of 1:2-dihydronaphthalene is  $1.4 \times 10^{-18}$  e.s.u. The polar asymmetry of the tetralin mol. is thus to be attributed mainly to a change in the C<sub>6</sub>H<sub>4</sub> nucleus. H. N. R.

**Liquid propane.** Electrical conductance and dielectric constant. G. GLOCKLER and R. E. PECK (J. Chem. Physics, 1936, 4, 624).—The conductivity is  $< 5 \times 10^{-13}$  ohm<sup>-1</sup> at 1 kilocycle between -90° and 15°. The dielectric const. at 0° is 1.61 and the temp. coeff. -0.00124. J. G. A. G.

**Molecular rotation in solid aliphatic alcohols.** C. P. SMYTH and S. A. MCNEIGHT (J. Amer. Chem.

Soc., 1936, 58, 1597—1600).—The dielectric consts. of solid MeOH, Bu<sup>n</sup>OH, and *n*-octyl alcohol (I) have been determined from liquid-air temp. to the m.p. There is evidence of dipole rotation in MeOH between 159.9° abs. and the m.p. Absence of dipole rotation in Bu<sup>n</sup>OH and (I) and the absence of transitions in many other alcohols show that OH does not rotate inside the mol., but the whole MeOH mol. rotates above the transition point (159.9° abs.).

E. S. H.

**Non-rotation of molecules in a number of solids.** S. A. McNEIGHT and C. P. SMYTH (J. Amer. Chem. Soc., 1936, 58, 1718—1722).—The dielectric consts. of solid NH<sub>2</sub>Me, Et<sub>2</sub>O, COMe<sub>2</sub>, CPh<sub>2</sub>, and succinic acid have been determined over a wide range of temp. and frequency. Mol. rotation cannot be postulated.

E. S. H.

**Molecular rotation of solid arsine and other hydrides.** C. P. SMYTH and S. A. McNEIGHT (J. Amer. Chem. Soc., 1936, 58, 1723—1728).—Dielectric consts. and sp. conductances of solid HCN and H<sub>2</sub>Se have been determined from liquid-air temp. to the m.p., and those of AsH<sub>3</sub> from liquid-H<sub>2</sub> temp. to the b.p. over the frequency range 0.5—50 kilocycles. Solid HCN shows no mol. rotation; H<sub>2</sub>Se mols. rotate freely even at liquid-air temp.; AsH<sub>3</sub> rotates freely down to 32.1° abs., where a transition, accompanied by anomalous dispersion, occurs. The mols. rotate the more readily the smaller are their dipole moments.

E. S. H.

**Indication of a decrease in the polarisability of a non-polar molecule by pressure.** A. MICHELIS, C. MICHELIS-VERAAT, and A. BIJL (Nature, 1936, 138, 509—510).—Graphs showing the relation between the Clausius-Mosotti function *P*, which  $\propto$  the polarisability of the mol., and *d*, the pressure, and the change in kinetic energy of the internal motion of the mols.,  $\Delta K$ , are reproduced from calculations based on recent isotherm data for CO<sub>2</sub>. The decrease of *P* with an increase in pressure and in  $\Delta K$  is practically linear.

L. S. T.

[Refractometry.] W. GEFFCKEN (Z. physikal. Chem., 1936, B, 33, 405).—Errors in previous papers (A., 1929, 1233; 1931, 905) are corr.

R. C.

**Refractive indices of ordinary and heavy ammonia.** O. E. FRIVOLD, O. HASSEL, and S. RUSTAD (Nature, 1936, 138, 330).—*n* for ND<sub>3</sub>, determined for various  $\lambda$  between 4358 and  $6562.9 \times 10^{-8}$  cm., is slightly  $< n$  for NH<sub>3</sub>.

L. S. T.

**Refractometric studies in normal methyl ketones.**—See this vol., 1363.

**Optical properties of non-polar liquids.** H. MUELLER (Physical Rev., 1936, [ii], 50, 547—559).—Mathematical. A theory of refraction, Kerr effect, and light scattering is developed from considerations of the quasi-cryst. grouping of neighbouring mols., the anisotropy of the Lorentz forces, and potential barriers of various heights. Results are applied to C<sub>6</sub>H<sub>6</sub>. Hindered rotation and cybotactic grouping suffice to explain deviations from classical theory.

N. M. B.

**Kerr constants of the hydrogen halide gases.** C. H. D. CLARK and E. C. HUMPHRIES (Nature,

1936, 138, 248).—Calc. vals., which appear to support the theory previously advanced (this vol., 1051), are given.

L. S. T.

**Kerr effect with nitrotoluene.** F. GABLER and P. SOKOB (Naturwiss., 1936, 24, 570).—The effect of temp. on the Kerr const., *B*, of *o*- and *m*-C<sub>6</sub>H<sub>4</sub>Me·NO<sub>2</sub>, at  $\lambda$  5461 Å. has been determined, and is expressed by empirical equations.

A. J. M.

**Polarisation of light and some technical applications.** A. F. C. POLLARD (Nature, 1936, 138, 311—314).

L. S. T.

**Magnetic rotation of lanthanum and neodymium chlorides in aqueous solution.** C. M. MASON, R. D. GRAY, and G. L. ERNST (J. Amer. Chem. Soc., 1936, 58, 1600—1604).—Data are recorded for  $\lambda$  5893 and 5460.8 Å. at 10—50° and compared with corresponding data for Al. The Verdet consts. of the solutions have been calc.; those for NdCl<sub>3</sub> vary linearly with 1/*T*. Mol. rotations of aq. NdCl<sub>3</sub> vary with temp. according to  $(T - 32.6)D = -790.1$ .

E. S. H.

**Calculation of the polarisation ellipsoid of a molecule.** T. NEUGEBAUER (Z. Physik, 1936, 102, 305—316).—A method for calculating change in polarisability of an ion due to external influence is described. Anomalies in the calc. polarisabilities parallel and perpendicular to the long axis of a mol. are due to incorrect application of methods for spherically symmetrical ions.

L. G. G.

**Structure of benzene. I. Problem and experimental method.** W. R. ANGUS, C. R. BAILEY, C. K. INGOLD, and C. L. WILSON. II. Direct introduction of deuterium into benzene and the physical properties of hexadeuterobenzene. C. K. INGOLD, C. G. RAISIN, and C. L. WILSON. (Appendix: Vapour pressure of hexadeuterobenzene. C. R. BAILEY and B. TOPLEY.) III. Raman spectra of liquid benzene and hexadeuterobenzene. W. R. ANGUS, C. K. INGOLD, and A. H. LECKIE. IV. Infra-red absorption spectra of liquid and gaseous benzene and hexadeuterobenzene. C. R. BAILEY, J. B. HALE, C. K. INGOLD, and J. W. THOMPSON. V. Fluorescence spectra of benzene and hexadeuterobenzene vapour. VI. Resonance emission spectrum of benzene and hexadeuterobenzene. C. K. INGOLD and C. L. WILSON. VII. Coincidental frequencies in the infra-red and Raman spectra of benzene and hexadeuterobenzene. VIII. Assignment of vibration frequencies of benzene and hexadeuterobenzene. W. R. ANGUS, C. R. BAILEY, J. B. HALE, C. K. INGOLD, A. H. LECKIE, C. G. RAISIN, J. W. THOMPSON, and C. L. WILSON (J.C.S., 1936, 912—915, 915—925, 925—931, 931—941, 941—954, 955—966, 966—971, 971—987).—I. The difficulty of reconciling the transformations of the aromatic nucleus with its stability is discussed. Although Pauling and Wheland's theory (A., 1934, 15) is successful in bringing the stability of the ring into line with its chemical transformations, it cannot explain certain difficulties, the most important of which is the appearance of identical frequencies in the Raman and infra-red spectra (see VII). Experimental methods for the

investigation are outlined. Since substitution of D for H does not alter nuclear changes, only effects arising from changes in at. masses influence vibration frequencies, and definite numerical relationships between the frequencies of corresponding normal vibrations of two isotopically related mols. are calculable if some mol. model is assumed. Only  $C_6H_6$  and  $C_6D_6$  are discussed; a scheme is given for investigating other D-substituted benzenes.

II. The exchange reaction,  $PhH + DO \cdot SO_3D \rightarrow PhD + HO \cdot SO_3D$  is utilised to prepare  $C_6D_6$  containing only 1% of  $C_6D_5H$ . Data for m.p., b.p., mol. vol., and mol. refraction for  $C_6D_6$  and for a series of partly deuterated benzenes are given and discussed. V.p. measurements with a differential tensimeter are recorded. A statistical treatment of the v.p. difference of isotopic mols. is developed to explain the higher v.p. of  $C_6D_6$ .

III. Raman spectra of  $C_6H_6$  and  $C_6D_6$  are obtained and compared with previous data. Peak and integrated intensities of the principal lines have been measured photometrically and are correlated by photographing an artificial mixture of 50 mols.-% of  $C_6H_6$  and  $C_6D_6$ . Polarizations of all the principal lines are recorded. The  $C_6H_6$  spectrum has 8 strong lines (fundamentals), 14 weak lines, 16 very weak lines, and 4 satellites of the strong line at  $992\text{ cm}^{-1}$ . For  $C_6D_6$ , 7 strong (fundamental) and 19 weak lines are found.

IV. To make comparison more trustworthy, the same samples of  $C_6H_6$  and  $C_6D_6$  were examined as vapour and as liquid between 1 and  $22\mu$ .  $C_6H_6$  vapour has 15 and liquid  $C_6H_6$  24 bands. Previous data are discussed and differences between results are explained, particularly for three bands previously recorded, but not now confirmed, for the vapour; these three bands, however, appear in the liquid  $C_6H_6$  spectrum.  $C_6D_6$  vapour gives 16 bands, liquid  $C_6D_6$  27. Mappings of the complete spectra, contours of strong bands, intensities, and  $P$ - $R$  and doublet separations are given and discussed.

V. The ideal case for the production of fluorescence and resonance spectra is outlined and experimental arrangements are detailed. The fluorescence spectra of both vapours are given and microphotometric intensities and series assignments are recorded. The spectra are accounted for by assuming 3 electron levels and 2 vibration frequencies; numerical formulæ are given.

VI. The resonance spectrum of  $C_6H_6$  falls into sections of  $989\text{ cm}^{-1}$  and 9 such sections are discussed; the eight component frequency differences are derived from which the series assignment of band max. is made. The corresponding spectrum of  $C_6D_6$  comprises sections each  $944\text{ cm}^{-1}$  in length and has 7 component frequency differences. Correlation of the  $C_6H_6$  and  $C_6D_6$  bands leads to a satisfactory pairing, 4 pairs being definitely identifiable. The other 3 pairs and a non-paired low frequency are provisionally characterised as fundamentals, inactive both in Raman and infra-red spectra.

VII. If the benzene mol. is a plane, regular hexagon and, therefore, has a centre of symmetry, selection rules forbid the appearance of the same frequencies in both infra-red and Raman spectra. Several coincident frequencies reported previously had led

to the conclusion that the mol. could not be a plane, regular hexagon. A table of 18 suggested coincidences in  $C_6H_6$  and 12 in  $C_6D_6$  is compiled from data in III and IV. By comparing Raman frequencies with infra-red frequencies of liquid  $C_6H_6$  more coincidences are found than with those of the vapour. Cohesive forces in the liquid deform the mol. sufficiently to cause a breakdown in strict selection rules and strong Raman frequencies appear in the liquid infra-red spectra but not in the vapour; strong infra-red frequencies appear faintly in Raman spectra: frequencies, inactive in both, appear fairly strongly in liquid infra-red, feebly in Raman, and are absent from infra-red vapour spectra. All the suggested coincidences are discussed and no evidence for the absence of a centre of symmetry is obtained.

VIII. In the theory of point groups the symbol which represents the symmetry classification of a plane, regular, hexagonal benzene model is  $D_{6h}$ ; those for the Kekulé and trigonally puckered models are  $D_{3h}$  and  $D_{3d}$ , respectively. The symmetry classifications of the vibrations of the three models are developed. Benzene has 20 normal modes of vibration. The  $D_{6h}$  model has 4 active in infra-red only, 7 active in Raman spectrum only (two polarised), and 9 forbidden in both spectra. For the  $D_{3h}$  model, there should be 8 fundamentals in the infra-red, 14 in Raman spectrum (4 polarised), and 7 common to both; whilst the  $D_{3d}$  model requires 8 in infra-red, and 9 in Raman spectra (4 polarised). By Teller's product theorem the products of the frequencies of vibrations of the same symmetry class for two isotopically related mols. are in a ratio which can be expressed as a function of the masses of the atoms and the moments of inertia. The numerical vals. for the ratios are given for the  $D_{6h}$  model. Experimental data are analysed and frequencies assigned for this model. Raman spectra give 7 strong lines (2 polarised); infra-red give 4 prominent bands: these are the allowed fundamentals. On applying Teller's product rule to these, very good agreement between calc. and observed ratios is found. The order of magnitude of the nine inactive frequencies is discussed and tentative vals. are given. The selection rules which govern the appearance of overtones and combination tones in these spectra are reviewed and assignments of the majority of the observed frequencies are made. The spectroscopic investigation of benzene, thus far, supports the  $D_{6h}$  model; there is no definite indication in favour of the  $D_{3d}$  structure. The Kekulé model fails to explain the facts.

W. R. A.

Structure of benzene. IX. Direct observation of the fluorescence spectra of benzene and hexadeuterobenzene vapour in the region of absorption. C. L. WILSON (J.C.S., 1936, 1210—1214; see preceding abstract).—The fluorescence spectra of  $C_6H_6$  and  $C_6D_6$ , excited by the Hg 2537 Å. line, have been measured at 0.1—0.3 mm., the resonance spectra being quenched by presence of  $N_2$  (760 mm.). The frequencies and relative intensities of the lines in the region 2577—2667 Å. are recorded. The results are in accord with previous data.

J. W. S.

**Investigation of the binding properties of benzene by physical methods.** R. KREMANN (Naturwiss., 1936, 24, 632—635).—A review of the application of physical methods to the study of the linkings in the  $C_6H_6$  mol. A. J. M.

**Structure and properties of mononuclear and polynuclear phenanthroline-ferric complexes.** A. GAINES, jun., L. P. HAMMETT, and G. H. WALDEN, jun. (J. Amer. Chem. Soc., 1936, 58, 1668—1674).—The analysis, hydration, conductivity, acid-base properties, magnetic susceptibility, and diffusibility of the brown, cryst. substance prepared by reaction of phenanthroline (I) and  $FeCl_3$  are consistent with the view that it is tetraphenanthrolinediol-diferric chloride. Other compounds probably exist in the mother-liquor. The low magnetic susceptibility suggests the partial neutralisation of the magnetic moments of the two Fe, and is evidence of a polynuclear structure. The magnetic susceptibility of the blue triphenanthroline- $Fe^{III}$  complex ion = approx. that of  $Fe(CN)_6^{4-}$ . Stable (I) complexes, the composition of which has been established in the solid state, may add more (I) in solution, forming secondary complexes of lower stability. E. S. H.

**Structure of the chlorine monoxide molecule.** R. POHLMAN and H. J. SCHUMACHER (Z. Physik, 1936, 102, 678—683).—An alternative interpretation of the infra-red measurements of absorption of  $Cl_2O$  by Bailey and Cassie (cf. A., 1933, 1228). O. D. S.

**Valency and molecular structure.** R. F. HUNTER and R. SAMUEL (Nature, 1936, 138, 411—413). L. S. T.

**Transition of covalency to electrovalency.** R. F. HUNTER and R. SAMUEL (Chem. and Ind., 1936, 733—740).—From consideration of potential energy relations in diat. mols. with at. binding, ionic binding, and hydrated ions, it is shown that covalency may pass over into electrovalency when the energy min. of the covalent and electrovalent states are sufficiently close for external forces (lattice energy, energy of solvation, van der Waals forces) to cause an intersection with the at. binding curve. The tendency for transition is dependent on the difference,  $J-E$ , between the ionisation energy of the cation  $J$ , opposing ionisation, and the electron affinity  $E$  of the anion, favouring ionisation. For compounds with a const. negative ion (e.g.,  $Cl^-$ ), the transition from covalency to electrovalency, as shown by the m.p., b.p., conductivity and hydrolysis of chlorides, runs strictly parallel to the variation of  $J$ . J. S. A.

**Energy of formation of "cyclol" molecules.** D. M. WRINCH (Nature, 1936, 138, 241—242).—Calculations of the approx. energy of formation of cyclol mols. from polypeptides (cf. this vol., 619) indicate that the linking process is facilitated if the appropriate groups are in the form  $\cdot C(OH) \cdot N \cdot$ , and that certain enzymes operate directly on the substrate by imposing this form on some of its  $\cdot CO \cdot NH \cdot$  groups. L. S. T.

**Energy of formation of "cyclol" molecules.** F. C. FRANK (Nature, 1936, 138, 242; cf. preceding abstract).—Estimation of the energy balance of the

linking process postulated for proteins by Wrinch (this vol., 619) indicates the necessity for assuming the existence of an additional source of energy similar to that provided by the strain in the side-chain cross-linkings found in keratin. Hydration also provides part of the necessary additional energy and helps to explain certain properties of proteins observed in degeneration and denaturation. L. S. T.

**Relation of the states of the carbon atom to its valency in methane.** H. H. VOGEL (J. Chem. Physics, 1936, 4, 581—591).—Resonance of  $C^{IV}$  with other valency configurations raises the stability of  $CH_4$  to a val. slightly  $>$  that calc. from the Pauling-Slater configuration. The relative energies of  $CH$ ,  $CH_2$ ,  $CH_3$ , and  $CH_4$  are 4.0, 8.0, 12.1, and 17.0 volts and thus there is no indication that  $CH_2$  is specially stable. This conclusion is discussed. J. G. A. G.

**Orbital valency according to an extended Heitler-London method.** G. NORDHEIM (Physical Rev., 1935, [ii], 47, 803—804).—An extension of the Heitler-London theory of chemical linking is developed to take into account not only the ground states but also the lowest excited states of the composing atoms. Directional properties of valency in polyat. mols. are explained. L. S. T.

**Intramolecular forces between bound atoms.** W. ALTAR (Physical Rev., 1935, [ii], 47, 804; cf. A., 1935, 1192). L. S. T.

**Provisional computation of the plane vibration frequencies of symmetrical deuterioethylenes.** C. MANNEBACK and A. VERLEYSSEN (Nature, 1936, 138, 367).—Calc. vibration spectra of  $C_2D_4$  and the three isomerides  $C_2D_2H_2$  are tabulated. L. S. T.

**Relation between the energy saturation and polarity of molecules.** V. RASUMOVSKI (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 21—27; cf. this vol., 925).—The "energy saturation" of mols.  $\propto$  the degree and duration of approach of the valency electrons to the individual at. in the mols.; the tendency to ionise is inversely, and to partake in addition reactions directly,  $\propto$  the energy saturation. These concepts are applied to some facts in org. chemistry. R. C. M.

CH. ABS. (e)

**Range of action of surface forces.** B. DERJAGUIN (*Nature*, 1936, 138, 330—331).—Bowden and Bastow's data (*A.*, 1935, 819) do not refute the author's findings that films of  $H_2O$   $< 1.5 \times 10^{-5}$  cm. thick have great rigidity.

L. S. T.

**Parachor.** R. LAUTIE (*Bull. Soc. chim.*, 1936, [v], 3, 1689—1691).—The parachor is shown to follow the formula  $[P] = 0.316P_c V_c$ , where  $P_c$  is expressed in atm. This relation also follows from Aten's formula (*A.*, 1935, 1059). The crit. temp. can be deduced from the parachor.

J. W. S.

**Parachor and the structure of formic acid.** S. K. RAY (*J. Indian Chem. Soc.*, 1936, 13, 484—485).—Published data are consistent with the structure.

E. S. H.

**Steady performance of Geiger-Müller counters.** B. DASANNACHARYA and G. S. RAO (*Nature*, 1936, 138, 289).

L. S. T.

**Characteristics of Geiger-Müller counters filled with different gases.** C. L. HAINES (*Physical Rev.*, 1935, [ii], 47, 791).

L. S. T.

**Application of the Geiger point-counter to the measurement of small X-ray intensities.** M. PAHL and A. FAESSLER (*Z. Physik*, 1936, 102, 562—571).—Apparatus for measuring the intensity of X-rays, of high sensitivity below  $\lambda$  800 X, is described.

O. D. S.

**Improved numerical method of two-dimensional Fourier synthesis for crystals.** H. LIPSON and C. A. BEEVERS (*Proc. Physical Soc.*, 1936, 48, 772—780).—Mathematical.

N. M. B.

**Reduction of space-groups.** F. SEITZ (*Physical Rev.*, 1935, [ii], 47, 810).

L. S. T.

**Structure-factor graphs for crystal analysis.** W. L. BRAGG (*Nature*, 1936, 138, 362—363).—The use of contoured graphs for determining the configuration of atoms in crystals from X-ray data is explained and illustrated. The analysis of at. positions can thus be expedited.

L. S. T.

**Tables for the determination of crystals.** A. K. BOLDIREV and V. V. DOLIVO-DOBROVOLSKI (*Z. Krist.*, 1936, 93, 321—367).—A summary of a forthcoming set of tables for the identification of crystal specimens from their crystallographic data. For each class of crystals, in the key the crystals are arranged in order of the polar distances of their faces [*i.e.*, angle between (001) and the perpendicular to the face] for all commonly occurring faces; in the sequel they are described fully. The process of identification is thus (1) measurement, (2) determination of the crystal class, (3) determination of the polar distance for each observed form, (4) search for corresponding vals. in the table, (5) confirmation from the details given.

B. W. R.

**Classification of crystal structures with defect lattices.** L. W. STROCK (*Z. Krist.*, 1936, 93, 285—311).—For "ideal solids" all positions in a theoretical

lattice are occupied by similar particles. If this condition is not fulfilled, there is a "defect lattice," varying in degree from the ideal solid to a state where the lattice of one kind of particle is completely destroyed. A classification is made on this basis of such defect lattices and detailed examples are given; it includes not only those defect lattices which are directly measurable by X-rays, but also the larger micro-lattices.

B. W. R.

**Theory of crystal growth.** R. KAISCHEV (*Z. Physik*, 1936, 102, 684—690).—The equation previously developed (*cf. A.*, 1934, 946) can be deduced kinetically.

O. D. S.

**Oxide layer on a polished surface.** L. H. CALLENDER (*Nature*, 1936, 138, 291).—Dobinski's results for Cu (this vol., 1055) are confirmed by experiments on polished Al (*B.*, 1927, 724).

L. S. T.

**Fourier analyses of X-ray patterns of phosphorus.** N. S. GINGRICH and R. HULTGREN (*Physical Rev.*, 1935, [ii], 47, 808; *cf. A.*, 1935, 919).

L. S. T.

**Crystal structure of black phosphorus.** R. HULTGREN and B. E. WARREN (*Physical Rev.*, 1935, [ii], 47, 808; *cf. A.*, 1935, 919).

L. S. T.

**X-Ray determination of residual atomic lattice deformation in pressed duralumin.** F. F. KOSOLAPOV and E. F. BACHMETEV (*Vestn. Metalloprom.*, 1934, 14, No. 3, 76—82).—Crystallites with dimensions  $> 10^{-1}$  cm. comprise the chief portion of the deformed duralumin. The change in the X-ray diagram is due to lattice distortion, which disappears at 200° (15 min.—1 hr.) or 300° (30 sec.).

CH. ABS. (e)

**Change of elastic parameters of single crystals of iron by heating.** K. NAKAMURA (*Sci. Rep. Tôhoku*, 1936, 25, 364—380).—The natural frequency of longitudinal and of torsional vibration of a no. of single crystals of Fe has been measured at intervals from 20° to 560°.

O. D. S.

**Intensity of X-rays reflected from zinc.** C. ZENER and S. BILINSKY (*Physical Rev.*, 1936, [ii], 50, 489; *cf. this vol.*, 273).—Discrepancies between calc. and experimental vals. of the consts. in the expression for the temp. dependence of the intensity are discussed.

N. M. B.

**Anisotropy in the atomic vibrations of zinc crystals.** I. Evidence from X-ray scattering. II. Diffuse scattering of X-rays from single crystals. G. E. M. JAUNCEY and W. A. BRUCE. III. (0002) and (1010) reflexions of Mo  $K\alpha$  X-rays from powdered zinc. R. D. MILLER and E. S. FOSTER, jun. (*Physical Rev.*, 1936, [ii], 50, 408—412, 413—416, 417—418).—I. A comparison of results of intensity measurements of the various reflexions of Cu  $K\alpha$  X-rays from powdered Zn crystals (*cf. Brindley, this vol.*, 3, 15, 538) and measurements on the diffuse scattering of X-rays from single crystals shows that the anisotropy of the thermal vibrations is previously supposed. The root mean square thermal displacements of the atoms are 0.172 and 0.093 Å. along and perpendicular to the *c* axis, respectively. The anisotropy almost explains the anomalous at. structure factor vals.  $F'$ , as modified

by thermal vibrations, for the (0002) and (1010) reflexions, and indicate some asymmetry in the electron structure of the atoms of the Zn crystal.

II. Experiments varying  $S$  with  $\psi$ , the orientation angle, for a fixed scattering angle  $\phi$ , and varying  $S$  with  $\phi$  for two fixed vals. of  $\psi$  confirm Zener's formula (cf. this vol., 273) for the Debye-Waller  $M$ , in the temp. factor  $e^M$  for hexagonal crystals, and the consts.  $a$  and  $b$  in the expression for  $M$ . Results give a higher anisotropy,  $a-b=1.66$ , than Brindley's val. 0.785.

III. The ratio of the  $F$  vals. for the two reflexions is 0.891, using an ionisation method, agreeing with Brindley's val. 0.894 for Cu  $K\alpha$  X-rays, using a photographic method. N. M. B.

**Asymmetry in metallic zinc and cadmium.** H. HERRMANN (Nature, 1936, 138, 290).—Certain discrepancies in the X-ray scattering factors of Zn and Cd (cf. this vol., 412) are ascribed to the asymmetry of the atoms rather than to that in the lattice vibrations. L. S. T.

**Asymmetry in metallic zinc and cadmium.** G. W. BRINDLEY (Nature, 1936, 138, 290—291).—A reply to Herrmann (cf. preceding abstract). The view that the lattice vibrations are responsible for the asymmetry is maintained. L. S. T.

**Eddy arrangement of micro-crystals in metallic wire caused by drawing.** T. FUJIWARA and Y. SEIKI (J. Sci. Hiroshima Univ., 1936, 6, 307—312).—Investigations for Al and W wires were made by X-ray radiographs and microscopically. N. M. B.

**Soft X-rays and photo-electrons from nickel at different temperatures.** S. R. RAO (Current Sci., 1936, 5, 73—74).—The photo-electric efficiencies ( $E$ ) of Cu and Ni when exposed to soft X-rays (applied potentials 100—150 volts) are independent of temp. in the range 30—500°.  $E$  for the 110 face of Ni is 12% < that of polycryst. Ni, this, it is suggested, being associated with the distortion of the crystal surface during bombardment. The soft X-ray emission from well degassed Ni increases with rise of temp., the rate of increase also increasing with rise of temp. No abrupt change was observed at the Curie point. It is concluded that the increase in secondary electron emission observed by Hayakawa (A., 1934, 233) at the Curie point and at potentials above a crit. val. is due to increasing nos. of electrons returning. J. W. S.

**Osmiridium.** III. O. E. ZVJAGINTZEV and B. K. BRUNOVSKI (Z. Krist., 1936, 93, 229—237).—Rotation and Laue photographs of osmiridium show a type of fibre structure in which the single crystal is divided into blocks set at angles up to  $\pm 10^\circ$  from each other. On this basis certain anomalous reflexions in the Laue picture are explained (cf. A., 1935, 440). B. W. R.

**Precision measurement of the lattice constant of very pure tantalum.** M. C. NEUBURGER (Z. Krist., 1936, 93, 312—313).— $a_0=3.2959 \pm 0.0003$  A. at 20°. B. W. R.

**Precision measurement of the lattice constant of very pure vanadium.** M. C. NEUBURGER (Z.

Krist., 1936, 93, 314—315).— $a_0=3.0338 \pm 0.0003$  A. at 25°. B. W. R.

**Crystal structure of heat-treated tungsten filaments.** R. P. BIEN (Physical Rev., 1935, [ii], 47, 806).—Well-aged filaments showed large crystals, up to 3 cm. in length, extending across the entire diameter of the filament. L. S. T.

**$\alpha$ - and  $\beta$ -Ice.** N. SELJAKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 227).—Orientations of  $\alpha$ - and  $\beta$ -ice crystals to the normal to the  $H_2O$  surface on which ice formation takes place are given from 0.5° to 10°. W. R. A.

**X-Ray analysis of vitreous  $B_2O_3$ .** B. E. WARREN and O. MORNINGSTAR (Physical Rev., 1935, [ii], 47, 808).—The X-ray scattering curve is that of a typically amorphous pattern showing four peaks. The distribution curve obtained from a Fourier analysis shows peaks at 1.4 and 2.38 A. for the B—O and O—O distances, respectively. A triangular co-ordination with each B linked to 3 O and each O to 2 B is indicated. L. S. T.

**Amorphous and crystalline oxide hydrates and oxides.** XXVIII. X-Ray structure and catalytic properties of silver ferrite. A. KRAUSE, Z. ERNST, S. GAWRYCH, and W. KOCAY (Z. anorg. Chem., 1936, 228, 352—356; cf. this vol., 947, 1080).—The crystal structures of various preps. of  $AgFeO_2$  are similar and show rhombohedral symmetry. The catalytic decomp. of  $H_2O_2$  by  $AgFeO_2$  is relatively slow. J. W. S.

**Crystal structure of cuprous ferrite.** W. SOLLER and A. J. THOMPSON (Physical Rev., 1935, [ii], 47, 644).— $CuFeO_2$ , rhombic,  $a$  5.96 A.,  $\alpha$  29° 26', one mol. per unit cell, space-group  $D_{3d}^3$ , is the only one of several forms of Cu ferrites which is slightly magnetic compared with the cubic form of  $Cu^{II}$  ferrite. L. S. T.

**Lattice constant of sodium chloride and rock-salt.** M. STRAUMANIS and A. IEVINŠ (Z. Physik, 1936, 102, 353—359).—The lattice const. of pure NaCl is  $5.6273 \pm 0.0000_2$  A. at 18°. Three specimens of natural rock-salt from different localities all give the val.  $5.6276_8 \pm 0.0000_3$  A. at 18°. From measurements between 18° and 67°, the coeff. of expansion is  $40.5 \times 10^{-6}$ . A. E. M.

**Crystal structure of germanium disulphide.** W. H. ZACHARIASEN (J. Chem. Physics, 1936, 4, 618—619).— $GeS_2$  crystals are orthorhombic; the unit cell,  $a$  11.66,  $b$  22.34,  $c$  8.86 A., contains 24 mols., and the space-group is  $Fdd$  ( $C_{2h}^{10}$ ). Each Ge is linked tetrahedrally with four S. The angle between two linkings is 103° and the Ge—S distance is 2.19 A. J. G. A. G.

**Interatomic distances in orpiment, realgar, sodium sulphoantimonate enneahydrate, and calcium mercuric bromide.** W. V. MEDLIN (J. Amer. Chem. Soc., 1936, 58, 1590—1592).—In orpiment and realgar the distance between As and S agrees with the sum of the corresponding covalent radii. In  $Na_3SbS_4 \cdot 9H_2O$  the Sb—S distance is < the sum of the covalent radii. Indefinite results were obtained with  $CaHgBr_4$ . E. S. H.

**Crystal structure of cupric chloride dihydrate.** D. HARKER (Z. Krist., 1936, 93, 136—145).— $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$  is orthorhombic,  $a_0$  7.38,  $b_0$  8.04,  $c_0$  3.72 Å., space-group  $Pbmn$ . The structure is found from intensity measurements. The Cu atoms are attached to 2 Cl and 2 O by covalent linkings directed to corners of a square. A similar square formation must occur in  $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$ . B. W. R.

**Crystal structure of ammonium chlorobromiodide.** R. C. L. MOONEY (Physical Rev., 1935, [ii], 47, 807—808).—The unit cell, containing 4 mols., has  $a$  6.14,  $b$  5.58,  $c$  10.03 Å.; space-group  $Pmcn$  ( $V^{16}$ ). Parameters for  $\text{NH}_4$ , Cl, I, and Br are given. The atoms lie in planes perpendicular to the  $x$ -axis and separated by a distance  $a/2$ . The halogen atoms are associated in a strictly linear group with I at the centre. The distance between I and Br atoms in a group agrees with the sum of the at. radii of I and Br as found in  $\text{I}_2$  and  $\text{Br}_2$  from band spectra.  $\text{NH}_4$  is co-ordinated with 4 Cl at a distance of 3.34 Å., 4 Br at one of 3.63 Å., and 2 I at one of 3.79 Å.

L. S. T.

**Crystal structure of thallium trithionate,  $\text{Tl}_2\text{S}_3\text{O}_6$ .** J. A. A. KETELAAR and J. K. SANDERS (J. Chem. Physics, 1936, 4, 621).— $\text{Tl}_2\text{S}_3\text{O}_6$  crystals are monoclinic and the unit cell,  $a$  13.20,  $b$  7.45,  $c$  7.58 Å.,  $\beta$  91.0°, contains 4 mols. The space-group is  $(C2/c)$ . The crystals are not isomorphous with  $\text{K}_2\text{S}_3\text{O}_6$ . J. G. A. G.

**X-Ray investigation of the structure of ultramarine-blue and its reaction products.** E. PODSCHUS, U. HOFMANN, and K. LESCHEWSKI (Z. anorg. Chem., 1936, 228, 305—333).—Ultramarine (I) has a cubic structure with a space-group  $T_d$ , similar to that of sodalite, hauynite, and nosean (cf. A., 1929, 749). The S is in a polysulphide state, probably with some in an ionic form. The structures of the Li and Ag substitution products are similar, but in the latter the position of the Ag ions is not quite ideal. The "sulphate-product" obtained by oxidising (I) has a lattice with space-group  $T_d$ . The S atoms are responsible for the colour of (I). J. W. S.

**X-Ray diffraction pattern of liquid and solid glycerol films.** K. LARK-HOROVITZ and E. P. MILLER (Physical Rev., 1935, [ii], 47, 813; cf. A., 1935, 18).—The apparent sharpening of diffracted lines at lower temp. is due to inhomogeneous radiation. None was observed at room temp. and at  $-80^\circ$ . This agrees with the view that the mols. in solid glycerol are distributed at random similarly to mols. in liquids. L. S. T.

**Physical investigation of phenyl  $\beta$ -hydroxy- $\beta\beta$ -diphenylvinyl sulphone.** H. E. BENT, E. S. LARSEN, and H. BERMAN (J. Amer. Chem. Soc., 1936, 58, 1522—1523).—Crystallographic and solubility (in  $\text{C}_6\text{H}_6$  and  $\text{MeOH}$ ) data are recorded and compared with corresponding data for Ph  $\alpha$ -hydroxy- $\beta\beta$ -diphenylpropenyl sulphone. The compounds may be identical. E. S. H.

**Lattice structure of condensed aromatic hydrocarbons and their molecular compounds with trinitrobenzene.** E. HERTEL and H. W. BERGK (Z. physikal. Chem., 1936, B, 33, 319—333).—2 : 3-

Benanthracene (I) crystallises in the triclinic system with  $I_a$  7.94,  $I_b$  6.02,  $I_c$  13.5 Å., and 2 mols. in the unit cell. Perylene (II) crystallises in the monoclinic system with  $I_a$  10.3,  $I_b$  10.8,  $I_c$  13.6 Å., space-group  $C_{2h}^2$ , and 4 mols. in the unit cell. The lattice structures of the 1 : 1 mol. compounds of (II) and pyrene with  $\text{C}_6\text{H}_5(\text{NO}_2)_3$  (III) have been examined. (I) forms no mol. compound with (III). The lattices of the 1 : 1 mol. compounds of (III) with  $\text{C}_6\text{H}_6$  and  $\text{PhMg}$  are able to take up small amounts of (I). An apparatus for vac. sublimation in a const. gas current is described. R. C.

**Absorption edges in the X-rays patterns of native and mercerised cellulose.** W. A. Sisson, G. L. CLARK, and E. A. PARKER (J. Amer. Chem. Soc., 1936, 58, 1635—1638).—Diffracted general radiation from the 002 and 101 planes in native and the 101 plane in mercerised cellulose produces Br and Ag absorption edges similar in appearance to diffraction lines on the X-ray negative. Absorption edges correspond with some, but not all, of the large interferences reported for cellulose. No spacings  $>$  the cellulose unit cell were found. E. S. H.

**Shape and properties of thread-like molecules in solution and in the elastic solid state.** W. KUHN (Z. Elektrochem., 1936, 42, 692; cf. A., 1934, 959; this vol., 785).—The mean distance between the ends of a long chain mol. is  $aZ$ , where  $Z$  is the no. of members in the chain and  $a$  is a const. The valency angle and nature of the free rotation modify the val. of  $a$ . The modulus of elasticity of rubber-like materials  $\propto 1/Z$ , and so can be used to determine the mol. wt. of the mols. J. W. S.

**Elementary lattice of crystallised caoutchouc.** K. H. MEYER and W. LOTMAR (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 61—62; cf. Mark, A., 1928, 1178).—Previous data are corr. The lattice is slightly monoclinic, with  $a$  8.54,  $b$  8.20,  $c$  12.65 Å.,  $\beta$  83°, space-group probably  $C_{2h}^2$ . N. M. B.

**Electron diffraction by transmission through thin silica glass films.** L. R. MAXWELL and V. M. MOSLEY (Physical Rev., 1935, [ii], 47, 330—331).—The electron diffraction pattern obtained by transmission of 25—38-kv. electrons through thin films of  $\text{SiO}_2$  glass is described. L. S. T.

**Structure of thin metal layers.** R. RIEDMILLER (Z. Physik, 1936, 102, 408—416).—The determination of lattice const. of Ni, Au, and Ag by electron diffraction through films vaporised on collodion is described. Various errors are eliminated by photographing a reference pattern simultaneously, and measuring the patterns microphotometrically. The effect of air and  $\text{H}_2$  on the films is studied. Lattice const. by this method are about 1%  $>$  by X rays. L. G. G.

**Structure of some metallic deposits on a copper single crystal as determined by electron diffraction.** W. COCHRANE (Proc. Physical Soc., 1936, 48, 723—735).—Ni, Cu, Zn, Cd, Ag, Cr, and Co were deposited electrolytically on etched Cu single-crystals and the structure of the deposits was found by electron diffraction. At small c.d. the layers are oriented except in the case of Zn and Cd. Irregul-

arities (lines and spots) in the Ni and Co patterns are accounted for by assuming repeated twinning on (111) planes. N. M. B.

Gerlach's thermomagnetic electromotive force in some ferromagnetic alloys. N. YAMANAKA (Sci. Rep. Tôhoku, 1936, 25, 174—183).—The e.m.f. produced by the application of a longitudinal magnetic field in a wire down which there is a temp. gradient has been measured for Ni, nichrome, ipvar, and superinvar. The effect for the alloys is  $<$  for Ni. When the temp. is  $<$  Curie point the e.m.f. increases with magnetic field and with temp., tending to a saturation val. O. D. S.

Time lag in the magnetisation of soft iron in the upper portion of the hysteresis loop. J. ÔKUBO and N. YAMANAKA (Sci. Rep. Tôhoku, 1936, 25, 163—173).—Measurements have been made of the time variation of magnetic induction in soft iron and Fe-Si-Al alloys after removal of a magnetising current under conditions where  $\mu$  was nearly const. O. D. S.

Magnetic viscosity at different points of the magnetisation curve. A. MITKEVITSCH (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 175—177).—The best conditions for the observation of the effect of magnetic history on magnetic viscosity are obtained, the magnetisation curve for an iron ring being found by the method of reversals. The viscosity reaches a max. on the steepest part of the curve and decreases exponentially with time. The effect of magnetic history on subsequent viscosity is most marked in weak fields, becoming imperceptible with increase of magnetic field. W. R. A.

Ferromagnetism of iron alloys. M. FALLOT (Ann. Physique, 1936, [xi], 6, 305—387).—The law of the approach to saturation magnetisation as a function of  $T^{3/2}$  near  $0^\circ$  abs. is verified. A special apparatus for liquefying small quantities of  $H_2$  for magnetisation experiments, and a recording apparatus for the determination of Curie points, are described. Mean at. moments and Curie points for alloys of Fe with Si, Al, Cr, V, Au, Sn, Pt, and Mn were determined and their variations with the nature and proportion of the added element are discussed. The at. moment of Fe depends on the foreign atoms surrounding the Fe atom in the lattice. N. M. B.

Hall coefficients of alkali metals. C. ZENER (Physical Rev., 1935, [ii], 47, 636).—Theoretical. L. S. T.

Determination of the optical anisotropy constants of absorbing crystal sections from polarisation observations in perpendicularly reflected light. M. BEREK (Z. Krist., 1936, 93, 116—135).—Mathematical. B. W. R.

Optical studies on organic crystals. I. K. S. SUNDARARAJAN (Z. Krist., 1936, 93, 238—248).—A summary of measurements of principal refractive indices and directions of optic axes for 14 aromatic hydrocarbons. The results are discussed in relation to the mol. positions already known from X-ray and magnetic methods. B. W. R.

Effect of crystal boundaries on test specimens consisting of several large crystals. G. SEUMEL (Z. Krist., 1936, 93, 249—283).—The behaviour of test-rods containing several large crystals is studied under strain, the normal polycryst. metal being regarded as the limiting case of such measurements. B. W. R.

Slip, twinning, and cleavage in silicon ferrite (4.17% Si). C. S. BARRETT (Physical Rev., 1935, [ii], 47, 809).—Repeated bending causes cleavage on cube planes [100], and hammering causes twinning (Neuman bands) on icositetrahedral planes [112]. Slip occurs only on rhombic dodecahedral planes [110]. L. S. T.

Crystalline symmetry and shear constants of Rochelle salt. T. TASCHKE and H. OSTERBERG (Physical Rev., 1936, [ii], 50, 572).—Interferometer studies of patterns due to shear modes of vibration excited by alternating electric fields of frequency 20—200 kc. per sec. show that, for 12 specimens, the cryst. symmetry is hemihedric with no transitions to the hemimorphic class in the temp. range  $0$ — $40^\circ$ . Frequency-temp. curves show negative temp. coeffs. for all three shear modes; all curves show anomalies near  $23.5^\circ$ . N. M. B.

Temperature variation of the elastic moduli of NaCl, KCl, and MgO. M. A. DURAND (Physical Rev., 1936, [ii], 50, 449—455; cf. Balamuth, A., 1934, 836).—The principal adiabatic and isothermal elastic moduli and elastic consts. were measured over  $270$ — $480^\circ$  abs. for NaCl,  $80$ — $280^\circ$  abs. for KCl, and  $80$ — $560^\circ$  abs. for MgO. The Debye characteristic temp. of these at  $80^\circ$  abs., calc. from the adiabatic elastic consts., are  $320^\circ$ ,  $246^\circ$ , and  $946^\circ$  abs., respectively. The variation of isothermals with temp. is evaluated and discussed. N. M. B.

High-pressure transitions of bismuth [and antimony]. P. W. BRIDGMAN (Physical Rev., 1935, [ii], 47, 427—428; cf. this vol., 146).—The transition parameters of Bi have been determined at high pressures. Two new modifications of Bi, each denser than the liquid, exist. The transition line between ordinary Bi (I) and the first high-pressure modification (II) is linear and passes through the points  $80^\circ$ , 23,250 kg. per sq. cm. and  $180^\circ$ , 17,850 kg. per sq. cm.; that between (II) and the second high-pressure Bi (III) is also linear and passes through  $80^\circ$ , 26,400 kg. per sq. cm. and  $180^\circ$ , 22,950 kg. per sq. cm. The triple point liquid-(I)-(II) occurs at  $184.0^\circ$  and 17,600 kg. per sq. cm. Estimated vals. for the triple point liquid-(II)-(III) are approx.  $187.0^\circ$  and 22,700 kg. per sq. cm. Sb shows no new modifications in the range examined. L. S. T.

Glassy state of arsenic. W. E. McCORMICK and W. P. DAVEY (Physical Rev., 1935, [ii], 47, 330).—In pure  $H_2$  below  $100^\circ$ , As vapour condenses to an amorphous (X-rays) powder of small particle size; between  $100^\circ$  and  $130^\circ$ , a mixture of powder and coherent sheet, and between  $130^\circ$  and  $250^\circ$  non-cryst. coherent sheet or glass, is obtained. Above  $250^\circ$ , the deposit is distinctly cryst. to X-rays. L. S. T.

Transformation of fluids into the glassy state. H. EBERT (Glastech. Ber., 1935, 13, 73—77; Chem.

Zentr., 1935, ii, 3812).—Glass, when cooled below the transformation interval, behaves as a frozen phase. The transformation curve does not afford decisive evidence of a transformation of higher order. J. S. A.

Osmotic mol. wt. determination for large molecules. G. V. SCHULZ (Z. Elektrochem., 1936, 42, 692).—The mol. wt. ( $M$ ) of large mols. can be calc. from their osmotic pressure ( $p$ ) in solution by the formula  $p = RTc/M(1 - cs)$  ( $c$  = concn.,  $s$  = vol. occupied in solution by 1 g. of solute).  $s$  is related to  $p$  by  $p - ks^v$ , where  $k$  and  $v$  are swelling consts. independent of mol. wt. and determinable for smaller mols. of known mol. wt. The vals. of  $M$  calc. from these equations are independent of concn. and are in accord with vals. deduced from viscosity and ultrafilter methods. The variation of  $p$  with  $c$  indicates that no mol. aggregation occurs at higher concn.

J. W. S.

Bismuth crystals. II. Variation of thermoelectric power in transverse magnetic fields. E. GRUNEISEN and J. GIELESSEN (Ann. Physik, 1936, [v], 27, 243—255; cf. this vol., 930).—The effect of transverse magnetic field on the thermoelectric power of couples of Bi crystals with metals unaffected by the field has been investigated at  $0^\circ$ ,  $-183^\circ$ , and  $-195^\circ$ , with respect to the direction of the field and of the crystal axis. For  $Bi_{II}$  at low temp. the thermoelectric power is increased by the magnetic field to an extent varying with the direction of the field. For  $Bi_I$  at low temp. the thermoelectric power is increased or decreased according to the direction of the field. In both  $Bi_{II}$  and  $Bi_I$  the thermoelectric power is affected by reversal of the field. The thermoelectric power of a  $Bi_{II}$ - $Bi_I$  couple at  $-183^\circ$  and  $-195^\circ$  is calc.

O. D. S.

Free path and thermoelectric effects. L. W. NORDHEIM (Physical Rev., 1935, [ii], 47, 794).—A general expression for the mean free path of electrons in metals is derived.

L. S. T.

Destruction of superconductivity by electric current and magnetic field. L. SCHUBNIKOV (Nature, 1936, 138, 545—546).—The data plotted for Sn show that as a necessary condition of superconductivity the magnetic field should be zero in the whole of the vol. and its effective tangential component should be  $\geq$  a crit. val. at any point of the surface of the superconductor.

L. S. T.

New phenomenon in the superconducting transition of tin and tantalum. F. B. SLSBEE, F. G. BRICKWEDDE, and R. B. SCOTT (Physical Rev., 1935, [ii], 45, 794).—With large currents, passage from the superconducting to the normal resisting condition is accompanied by a spontaneous, transitory increase in resistance followed by a slower return.

L. S. T.

Electron theory in metals of any crystal form. M. KOHLER (Ann. Physik, 1936, [v], 27, 201—216).—Mathematical. Theory of electrical conductivity, thermoelectric effect, and the galvanomagnetic phenomena is generalised for metals of any crystal form.

O. D. S.

Effect of electric field on the heat current in gases. H. SENFTLEBEN and W. BRAUN (Z. Physik, 1936, 102, 480—506).—A thin wire heated in an electric field gives out more heat than without the field. The effect was investigated in A and O<sub>2</sub> (non-polar gases) and in EtCl (polar), with variation of pressure, external temp., and temp. of wire. In all cases the effect varied with the square of the field strength, pressure, and temp. of wire. The val. decreased rapidly with increase of external temp. The effect in polar gases is  $>$  in non-polar gases. It can be explained as a supplementary convection due to variations in electrostriction, and offers a method of determining the latter in gases. A. J. M.

(A) Magnetic properties of chromium. L. F. BATES and A. BAQI. (B) Magnetic properties of amalgams. L. F. BATES and L. C. TAI (Proc. Physical Soc., 1936, 48, 781—794, 795—809).—(A) The magnetic susceptibility of pure Cr prepared from Cr amalgam was investigated over the temp. range  $90$ — $620^\circ$  abs. The mass susceptibility is almost const.; the mean susceptibility is  $3.08 \times 10^{-6}$  e.m.u. per g. at room temp. The effects of impurities are considered in detail, and thermal and magnetic data are discussed on the basis of modern theories of paramagnetism.

(B) The magnetic susceptibilities of a series of amalgams of known concn. of Bi, Cr, Cu, and Mn were studied at room temp. by the Gouy method, the drop-wt. method being untrustworthy for amalgams. The apparent at. susceptibilities in dil. amalgams were: Mn,  $0.137$ ; Bi,  $133 \times 10^{-6}$ ; Cr,  $23 \times 10^{-6}$ ; Cu,  $-7.3 \times 10^{-6}$  e.m.u. Metals diamagnetic in the solid state were paramagnetic in dil. amalgams, with the possible exception of Cu. N. M. B.

Paramagnetism of the rare-earth sulphates at low temperatures. L. C. JACKSON (Proc. Physical Soc., 1936, 48, 741—746).—Measurements of magnetic susceptibilities of powdered octahydrated sulphates of Yb, Dy, and Er are plotted from room temp. to  $14^\circ$  abs. Results are discussed in terms of the cryst.-field theory of Penny (cf. A., 1932, 985). Measurements on  $Nd_2(SO_4)_3 \cdot 8H_2O$  support Gorter (cf. *ibid.*, 448) against Selwood (cf. A., 1933, 1002).

N. M. B.

Acoustical studies. V. Collision efficiencies of deuterium and hydrogen in exciting the lower vibrational states of ethylene. W. T. RICHARDS. VI. Behaviour of formic and acetic acid vapours. C. O. STROTHER and W. T. RICHARDS (J. Chem. Physics, 1936, 4, 561—566, 566—569; cf. A., 1934, 588).—V. Sound velocity data in  $C_2H_4$ - $D_2$  mixtures show that a  $H_2$ - $C_2H_4$  collision is eight times as effective as a  $D_2$ - $C_2H_4$  collision in producing transitions in the lower vibrational states of  $C_2H_4$ . The origin of this difference may be found in the uniquely small moment of inertia of  $H_2$ .  $C_3H_8$  behaves as an inert gas in  $C_2H_4$ - $C_3H_8$  mixtures. The claim to have found rotational dispersion in  $H_2$  is withdrawn.

VI. Thermal decomp. of formic acid at  $60^\circ$  prevents accurate sound velocity measurements. Data for AcOH at  $85$ — $115^\circ$  show that the rate of dissociation of the double mols. is  $> 10^4$  sec.<sup>-1</sup> at  $85^\circ$  and 174 mm.

J. G. A. G.

**Propagation of sound in partly dissociated gases.** H. O. KNESER and O. GAULER (Physikal. Z., 1936, 37, 677—684).—Theoretical. The effect of partial dissociation of a gas on the velocity of waves of short and of long  $\lambda$ , respectively, through it is discussed, and applied to the case of  $\text{N}_2\text{O}_4$  and  $2\text{NO}_2$ .  
A. J. M.

**Current, breakdown, and supersonic vibrations in dielectric liquids.** W. MEYER (Z. Physik, 1936, 102, 279—304).—The influence of supersonic vibrations on the conductivity and dielectric strength of  $\text{C}_6\text{H}_{14}$ ,  $\text{PhCl}$ ,  $\text{Et}_2\text{O}$ ,  $\text{CCl}_4$ ,  $\text{PhMe}$ , and  $\text{COMe}_2$  has been investigated. Results are affected by the nature of the electrode surfaces and by the presence of dissolved gas and other impurities in the liquids. The incidence of supersonic vibrations causes a general increase in conductivity and a decrease in dielectric strength.  
H. C. G.

**Intensity measurements in the diffraction of light by ultrasonic waves.** F. H. SANDERS (Canad. J. Res., 1936, 14, A, 158—171).—The relative intensities in the various orders of the diffraction pattern produced when light is passed through a liquid carrying ultrasonic waves have been measured for various ultrasonic intensities and for both progressive and standing wave-fields. The variation with intensity is in accord with the theory of Raman and Nath (this vol., 148, 555).  
J. W. S.

**Absorption of ultrasonic waves by liquids.** P. BIQUARD (Ann. Physique, 1936, [xi], 6, 195—304; cf. this vol., 417).—Using the method of measuring the radiation pressure exerted on an obstacle or an optical method based on diffraction, the absorption in  $\text{H}_2\text{O}$  and several org. liquids of ultrasonic waves of frequency  $(4-11) \times 10^6$  was investigated. Absorption coeffs. differed widely from theoretical predictions and the law of proportionality of absorption to  $v^2$  was not always obeyed. Various explanations are discussed.  
N. M. B.

**Absorption of ultrasonic waves in liquids and related optical phenomena.** L. MANDELSTAM and M. LEONTOVITSCH (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 111—114).—Theoretical. The dependence of the absorption coeff. of ultrasonic waves in liquids on frequency and other factors is discussed, and related to the diffraction of light in the transmitting liquid.  
A. J. E. W.

**Thermal and caloric equation of state of condensed hydrogen isotopes. I. Determination of magnitudes of state.** E. BARTHOLOME (Z. physikal. Chem., 1936, B, 33, 387—404).—The results of measurements of the isothermal compressibility of liquid  $\text{H}_2$  and  $\text{D}_2$  at 16—21° abs. agree with Eucken's equation of state for a condensed substance (A., 1934, 946); the compressibility falls rapidly with increasing pressure. From measurements of the change in vol. on melting under pressure, part of the fusion curve has been traced, and the latent heats of fusion have been calc. The mol. vol. at 0° abs. of  $\text{H}_2$  and  $\text{D}_2$  are calc. to be 22.9 and 20.3 c.c., respectively. The characteristic temp. of the Debye sp. heat function are 105° and 97° for solid  $\text{H}_2$  and  $\text{D}_2$ , respectively, the deviation of the ratio of these vals.

from the theoretical val.  $\sqrt{2} : 1$  being attributed to the anharmonicity of the potential curve of solid  $\text{H}_2$ . From  $C_p$  for the liquids, compressibilities have been calc. The results obtained have been used to construct pressure-vol.-temp. and enthalpy-pressure-temp. diagrams for  $\text{H}_2$  and  $\text{D}_2$ .  
R. C.

**Determination of heat capacities and heat capacity ratios of gaseous hydrogen cyanide and hydrogen sulphide.** W. A. FELSING and G. W. DRAKE (J. Amer. Chem. Soc., 1936, 58, 1714—1717).—Heat capacities have been determined at 30—148° for HCN and 30—110° for  $\text{H}_2\text{S}$  with an accuracy of approx. 1%.  $C_p/C_v$  has been determined at 30—75° for HCN and at 10—75° for  $\text{H}_2\text{S}$  with an accuracy of approx. 0.2%.  
E. S. H.

**Thermodynamic properties of methane.** W. C. EDMISTER (Ind. Eng. Chem., 1936, 28, 1112—1116).—Vals. of  $(dc_p/dP)_T$ ,  $c_p - c_v$ , Joule-Thomson coeff.,  $S$ , enthalpy, and  $\alpha = RT/P - V$  for  $\text{CH}_4$  at pressures 1 to 120 atm. and temp. —70° to 200° have been calc. from existing compressibility and sp. heat data.  
C. R. H.

**Effect on the fundamental units of volume and temperature of the variable isotopic composition of water.** E. H. RIESENFELD and T. L. CHANG (Physikal. Z., 1936, 37, 690—692).—The effect of the variability in composition of  $\text{H}_2\text{O}$  from different sources on the accuracy of the definition of the litre and of the Centigrade degree is discussed, and it is concluded that owing to the difficulty of obtaining pure  $^1\text{H}_2^{16}\text{O}$  it would be unwise to alter the present definitions. It would, however, be an advantage to specify the source and treatment of the  $\text{H}_2\text{O}$  referred to in the definitions.  
A. J. M.

**Density and compressibility of solid hydrogen and deuterium at 4.2° absolute.** H. D. MEGAW and F. SIMON (Nature, 1936, 138, 244).—Approx. vals. of  $d$ , compressibility, and thermal expansion of H and D at 4.2° abs. have been determined in order to show the effect of zero-point energy.  
L. S. T.

**Density and coefficient of expansion of liquid gallium over a wide range of temperature.** W. H. HOATHER (Proc. Physical Soc., 1936, 48, 699—707).—Accurate data for  $d$  and coeff. of expansion for the temp. range 30—1000°, obtained by a dilatometric method, are reported. An equation for vol. increase with temp. is found. The calc. mean coeff. of expansion (32.38—310°) is  $118.7 \times 10^{-6}$ .  
N. M. B.

**Density of hydrocarbon gases and vapours at high temperature and pressure.** W. B. KAY (Ind. Eng. Chem., 1936, 28, 1014—1019).— $P$ ,  $V$ , and  $T$  data on eleven petroleum hydrocarbon mixtures are correlated with similar data on pure hydrocarbons by means of the theory of corresponding states. For the mixtures,  $P_r$  and  $T_r$  are related to a "pseudocrit. point," which is the crit. point of the pure compound of which the  $P$ ,  $V$ ,  $T$  relations in the superheated region are identical with those for the mixture.  
C. R. H.

**Reduced volume at the b.p. and additivity.** R. LAUTIE (Bull. Soc. chim., 1936, [v], 3, 1595—1600).

—The reduced density at the b.p. ( $T^\circ$  abs.) is not const. but varies according to  $d_c/d_e = 2.23 + 0.1861 \log T_e - 8.03 \times 10^{-5} T_e$  to within 2.5%. J. W. S.

**Vapour pressure of potassium chloride and caesium iodide crystals.** V. DIETZ (J. Chem. Physics, 1936, 4, 575—580).—The v.p. determined by means of a modified abs. manometer are for KCl,  $\log_{10} \text{ dynes} = -11,300/T + 13.461$  between  $847^\circ$  and  $936^\circ$  abs. and for CsI,  $\log_{10} P_{\text{dynes}} = -10,360/T + 13.793$ , at  $767$ — $847^\circ$  abs., from which the heats of sublimation are 51,800 and 47,500 g.-cal. per mol., respectively. Effusion experiments show that the mols. are not associated. J. G. A. G.

**Vapour pressure curves and triple points in the temperature range  $14$ — $90^\circ$  abs.** F. HENNING and J. OTTO (Physikal. Z., 1936, 37, 633—638).—Data for the v.p. curves of  $\text{H}_2$ , Ne,  $\text{O}_2$ , and  $\text{N}_2$  between the triple point and the b.p. have been obtained using the He gas thermometer. Empirical equations expressing variation of v.p. with temp. are given. For Ne the v.p. of the solid is also given. The triple points are:  $\text{H}_2$   $13.96^\circ$ , 54.1 mm., Ne  $24.56^\circ$ , 325 mm., N,  $63.145^\circ$ , 94.6 mm.,  $\text{O}_2$   $54.33^\circ$ , 1.2 mm. (all temp. abs.). A. J. M.

**Derivation of the equation  $PV = RT$ .** L. McCULLOCH (J. Chem. Educ., 1936, 13, 393—394). L. S. T.

**Generalised high-pressure properties of gases.** K. M. WATSON and R. L. SMITH (Nat. Petroleum News, 1936, 28, No. 27, 29—36).—Methods which are simpler than the ordinary thermodynamic formulæ are derived for calculating the effect of pressure on heat content, heat capacities, and the Joule-Thomson coeff. from the activity coeffs. Plots of the authors' correlations of compressibility factor ( $PV/RT$ ) and activity coeffs. are presented. R. B. C.

**Joule-Thomson coefficient of oxides of carbon.** T. C. HUANG, F. LIN, and C. Y. FU (Z. Physik, 1936, 102, 422).—A correction (this vol., 930). For CO read  $\text{CO}_2$ . H. C. G.

**Thermal conductivity of deuterium.** C. T. ARCHER (Nature, 1936, 138, 286—287).—Vals. obtained for the thermal conductivity at  $0^\circ$  of  $\text{D}_2$  prepared by two different methods from 99.95%  $\text{D}_2\text{O}$  are 0.000308<sub>2</sub> and 0.000307<sub>8</sub> g.-cal. per cm. per sec. per degree. L. S. T.

**Thermal conductivity of gases with free convection.** W. WEIZSACKER (Physikal. Z., 1936, 37, 641—650).—The effect of pressure on the free convection of  $\text{CO}_2$ , A,  $\text{H}_2$ , He, and air for small temp. differences has been investigated. The convection disappears at a temp. characteristic for each gas. A. J. M.

**Viscosity of deuterium.** H. C. TORREY (Physical Rev., 1935, [ii], 47, 644—645).—Rankine's method gives for the ratio  $\eta_{\text{D}_2} : \eta_{\text{H}_2}$   $1.410 \pm 0.03$ , yielding  $124.4 + 2.5$  micropoises for the  $\eta$  of  $\text{D}_2$  at  $23.0^\circ$ . The mol. cross-sections of the H isotopes effective in  $\eta$  thus differ by  $<2\%$ . L. S. T.

**Physical properties of water and other fluids.** R. L. DAUGHERTY (Trans. Amer. Soc. Mech. Eng., 1935, 57, 193—196).— $\eta$  data for  $\text{H}_2\text{O}$  and various

liquids are represented graphically.  $P$ — $V$ — $T$  data and vol. modulus of elasticity and sp. heat data for  $\text{H}_2\text{O}$  are given. CH. ABS. (e)

**Fluidity and molecular complexity.** E. C. BINGHAM and C. E. COOMBS (Physical Rev., 1935, [ii], 47, 645).—Formulæ connecting fluidity and mol. complexity are discussed for normal org. compounds. L. S. T.

**Effect of an electric field on the viscosity of eolotropic liquids.** Y. BJORNSTAHL (Physics, 1935, 6, 257—264).—An oscillating-disc viscosimeter with connexions for applying a field parallel to the axis of the instrument was used.  $\eta$  increased with increase of either an a.c. or a d.c. field, probably owing to orientation of swarms. A change in electrical conductivity with shear was found. CH. ABS. (e)

**Viscosity of aqueous solutions. III. Calculation of the viscosity of mixed solutions.** A. BANCHETTI (Gazzetta, 1936, 66, 446—451; cf. A., 1935, 693).—The validity of various formulæ for calculating the viscosity of mixed solutions has been examined for solutions of  $\text{NaCl} + \text{HCl}$ ,  $\text{NaCl} + \text{KCl}$ , and  $\text{HCl} + \text{KCl}$ . O. J. W.

**Viscosity of supersaturated solution of sucrose.** J. COUMOU (Chem. Weekblad, 1936, 33, 542—544).—For supersaturated solutions (75%) of sucrose at  $20^\circ$   $\eta$  decreases to a const. val. on keeping for 2—3 hr. and increases when the solution is vigorously stirred. S. C.

**Binary liquid systems in which compounds are formed.** E. ANGELESCU and C. EUSTATIU (Z. physikal. Chem., 1936, 177, 263—276).—Mixtures of aromatic amines with fatty acids at  $25^\circ$  have been studied. The contraction on mixing,  $\phi$ , may be represented by  $\phi = Kx^a(1-x)$ , where  $x$  is the mol. fraction and  $K$  and  $a$  are consts. The relation between the viscosity,  $\eta$ , and vol. composition of the mixtures may be represented by McLeod's equation (Trans. Faraday Soc., 1924, 19, 6, 17). is a max. for a mixture containing a greater proportion of acid than corresponds with the composition of the compounds indicated by thermal analysis, a discrepancy which is ascribed to the acids being more highly associated than the amines. Neither the mol. surface energy nor the parachor follows the additive law, but each may be represented by  $P = [P_1x + P_2(1-x)](1 - K'\phi)$ , where  $P$  is the parachor or mol. surface energy and  $K'$  a const. which is the greater the more capillary active is the acid. The mol. refraction is approx. additive, but  $n$  deviates from additivity, the deviation being a max. for a mixture of one mol. of amine with two mols. of acid. R. C.

**Properties of metallic solutions. I.** V. K. SEMENTSCHENKO (Acta Physicochim. U.R.S.S., 1936, 4, 695—704; cf. this vol., 1192).—The surface tension of amalgams of Mg, Co, Zn, Cd, Ag, Ca, Sr, Pb, Sn, Ba, Li, Na, K, Rb, and Cs has been determined for various concns. There is good agreement with the theory of generalised moments. The effect of minute quantities of impurities on the mechanical properties of metals and alloys, and that of surface-active metals on the mutual solubility of two metals

are discussed. The action of promoters may be explained on the theory. A. J. M.

**Diffusion constant and valency of silver in liquid silver amalgam.** K. SCHWARZ and R. STOCKERT (*Monatsh.*, 1936, 68, 383—368).—The diffusion const. of Ag in Ag amalgam at 16° is  $1.1 \times 10^{-5}$  sq. cm. per sec., in accord with the bivalency of Ag in these amalgams. J. W. S.

**Heat content and heat of formation of molten alloys.** H. O. VON SAMSON-HIMMELSTJERNA (*Z. Metallk.*, 1936, 28, 197—202).—The heat contents of Pb-Bi alloys at 400°, 500°, and 600°, Sn-Bi, Pb-Sn, and Pb-Cd alloys at 500°, Pb-Ag alloys at 1000°, and Pb-Sn-Bi alloys at 500° have been determined. The max. heats of alloying calc. from these figures are at 500°: Pb-Bi +1000, Bi-Sn +530, Pb-Sn -250 and Cd-Pb -480 g.-cal. per g.-atom; and at 1000° Pb-Ag -800 g.-cal. per g.-atom. The heats of formation of solid Ag-Zn alloys lie on two straight lines intersecting at  $\text{Ag}_2\text{Zn}_3$ , and those of solid Cu-Zn alloys on straight lines intersecting at  $\text{Cu}_2\text{Zn}_3$ ; calculations of the heat of formation of these alloys at 1000° show that these compounds exist in the liquid state but are strongly dissociated unless a large excess of either component is present. The heats of alloying of Cu and Ni and of Ni and Fe at 1500—1600° vary only slightly from the heats of formation of the corresponding solid solutions. A. R. P.

**Relation between the thermal and electrical conductivities of copper alloys.** C. S. SMITH (*Physical Rev.*, 1935, [ii], 48, 166—167).—When thermal conductivity is plotted against electrical conductivity at the same temp., the results for all Cu alloys can be represented by a single curve, regardless of composition within wide limits and also of structure or heat-treatment. The curves for 20° and 200° differ in slope, but intersect at approx. the same point on the thermal conductivity axis. All results both at 20° and 200° lie on a single curve when thermal conductivity is plotted against electrical conductivity  $\times$  abs. temp. L. S. T.

**Hall effect and some other physical constants of alloys. V. Antimony-silver series.** W. G. JOHN and E. J. EVANS (*Phil. Mag.*, 1936, [vii], 22, 417—435).—The resistivity, temp. coeff. of resistance, thermo-electric power,  $d$ , and Hall coeff. of Sb-Ag alloys have been determined over the complete composition range. The property-composition curves afford no evidence for the existence of a solid solution at the Sb end of the series. Sharp negative max. occur in the thermo-electric power and Hall coeff. curves at 72% Ag, but  $X$ -ray analysis shows no sign of a phase change at this composition. A. J. M.

**Magnetic susceptibilities of the silver-lead, silver antimony, and silver-bismuth series of alloys.** G. O. STEPHENS and E. J. EVANS (*Phil. Mag.*, 1936, [vii], 22, 435—445).—The  $d$  and mass susceptibilities ( $\chi$ ) of Ag-Pb, Ag-Sb, and Ag-Bi alloys have been determined. Annealing has little effect on  $\chi$  for Ag-Pb alloys, which represent a series of mechanical mixtures throughout the whole composition range. In the Ag-Sb alloys no indication is found of the existence of a solid solution at the Sb

end of the system (cf. preceding abstract). The existence of a solid solution of Bi in Ag up to a concn. of 5.7% Bi is shown. All the alloys examined were diamagnetic. A. J. M.

**Longitudinal magneto-resistance effect at various temperatures in nickel-copper alloys.** H. MASUMOTO and Y. SHIRAKAWA (*Sci. Rep. Tohoku*, 1935, 25, 105—127).—The magneto-resistance of Ni-Cu alloys rises with increasing Cu content to a max. at 10% (−195°), 6% (0°), and 4% Cu (100°) and then falls rapidly, reaching zero at 47% (−195°), 33% (0°), and 23% Cu (100°). The max. in the curves is much more pronounced at temp. below 0° than at higher temp. A. R. P.

**Quantum theory of electrical conductivity of alloys in superlattice state.** T. MUTO (*Sci. Papers Inst. Phys. Chem. Res. Tokyo*, 1936, 30, 99—120).—Theoretical. An expression is derived which connects the influence of temp. and composition on the resistance with the superlattice order of the alloy. Comparison with published results for the Cu-Au system shows fair agreement. J. S. A.

**Diffusion experiments as means of simple micrographic detection of compound formation between alloy components in three- and multi-component systems.** M. BOSSHARD (*Aluminium*, 1935, 17, 477—481; *Chem. Zentr.*, 1935, ii, 3972—3973).—A cone of the basis metal with one alloy component is pressed into a corresponding seating in a block of an alloy of the basis metal with the second alloying component. After several days just below the solidus temp. the region of the interface is examined micrographically for evidence of diffusion. In the following combinations the changes indicated were so detected: Al-Si: Al-Fe,  $\text{Al}_3\text{Fe} \rightarrow \text{Al}_x\text{Fe}_y\text{Si}_z$  (probably  $\text{Al}_6\text{Fe}_2\text{Si}_3$ ); Al-Si: Al-Mn, MnSi formed; Al-Cr: Al: Si,  $\text{Al}_2\text{Cr} \rightarrow \text{CrSi}$ , with vol. contraction; Al-Fe: Al-Cu,  $\text{Al}_3\text{Fe} \rightarrow \text{Al}_2\text{Cu}_2\text{Fe}$ ; Al-Ni: Al-Cu,  $\text{Al}_5\text{NiCu}_2$  or Al-NiCu<sub>2</sub> formed; Al-Cu: Al-Mg,  $\text{Al}_6\text{Mg}_4\text{Cu}$  formed. J. S. A.

**Stability of cementite.** K. HONDA, K. IWASE, and K. SANO (*Sci. Rep. Tohoku*, 1936, 25, 202—206).—Theoretical. The solubility curve of graphite in austenite is deduced from the equilibrium const. of the reactions: austenite (C-rich) +  $\text{CO}_2$  = austenite (C-poor) + 2CO, and  $\text{C} + \text{CO}_2 = 2\text{CO}$ . The solubility of graphite above 925° is > that of cementite; it is inferred that cementite is stable above this temp. O. D. S.

**System iron-zinc.** J. SCHRAMM (*Z. Metallk.*, 1936, 28, 203—207).—The system has been examined by  $X$ -ray, thermal, and magnetic analysis and by micrographical methods. At 20° there are four stable phases:  $\eta$  (hexagonal Zn-rich solid solution,  $\delta$  (hexagonal "FeZn<sub>2</sub>"),  $\Gamma$  (cubic "FeZn<sub>3</sub>" with 52 atoms in the unit cell), and  $\alpha$  (Fe-rich solid solution). The eutectic point is 419.4°, 0.09% Fe and < 0.03% of Fe dissolves in Zn at the eutectic temp. The  $\delta$ -field extends from 6.3 to 11.5% Fe at 20° and from 5.8 to 11.5% Fe at 419° and the  $\Gamma$ -field from 20 to 27% Fe at 20—600°. The peritectic horizontal at 780° extends from 54 to 19% Fe, and that at 668° from 20 to 4% Fe, whilst the eutectoid horizontal at 623°

extends from 80 to 27% Fe;  $\alpha$ -Fe dissolves 20% Zn at 623°, 10% at 450°, and 8% at 20°, but  $\gamma$ -Fe dissolves a max. of 46% Zn at 780°. The compositions of the  $\delta$ - and  $\Gamma$ -phases are not in agreement with any of the formulæ previously proposed. A. R. P.

**Equilibrium diagram of magnesium-rich magnesium-manganese binary system.** H. SAWAMOTO (Suiv.-Shi, 1935, 8, 763—768; cf. this vol., 559).—The new  $\beta$ -phase in the Mg-Mn system is a solid solution of the compound  $\text{Mg}_6\text{Mn}$ , which is formed by the peritectic reaction at 726°.

CH. ABS. (e)

**Phase relationships in the nickel-tin system.** E. FETZ and E. R. JETTE (J. Chem. Physics, 1936, 4, 537).—With increasing % of Sn, a new phase appears at  $\text{Ni}_3\text{Sn}$  which coexists at 25—35.5 at.-% Sn with a phase (I) having a NiAs-structure. (I) exists alone at 35.5—45 at.-% Sn, but at 40 at.-% Sn and below 500° gives place to a deformed modification. Three new phases,  $\eta$ ,  $\theta$ , and  $\epsilon$ , exist at 51, 54, and 56—62 at.-% Sn, respectively. The  $\zeta$ -phase coexists with the Sn-phase above 62 at.-% Sn. The solubility of Ni in Sn is very small. J. G. A. G.

**Phase equilibria in hydrocarbon systems.** XVI. Solubility of methane in four light hydrocarbons. B. H. SAGE, D. C. WEBSTER, and W. N. LACEY (Ind. Eng. Chem., 1936, 28, 1045—1047).—The solubility of  $\text{CH}_4$  in  $n\text{-C}_5\text{H}_{12}$ ,  $n\text{-C}_6\text{H}_{14}$ , cyclohexane, and  $\text{C}_6\text{H}_6$  and the sp. vols. of the mixtures have been determined at 100°, 160°, and 220° F. and at total pressures between 400 and 3000 lb. per sq. in. C. R. H.

**Solubility of calcium  $\beta$ -methylbutyrate in water.** D. F. HOUSTON (J. Res. Nat. Bur. Stand., 1936, 17, 55—58).—Solubilities at 0—100° are recorded. The results indicate a transition from the penta- to the hemi-hydrate at 36.5°. O. J. W.

**Solubility of sodium carbonate in aqueous ammonia.** E. I. ACHUMOV and E. A. EZEROVA (J. Appl. Chem. Russ., 1936, 9, 1173—1177).—Solubility data are recorded, for the system  $\text{Na}_2\text{CO}_3\text{--NH}_3\text{--H}_2\text{O}$ , at 0°, 10°, and 20°. R. T.

**Equilibrium in fluoride systems. I. Solubility of cryolite in aqueous solutions of iron and aluminium salts at 25°.** F. J. FRERE (J. Amer. Chem. Soc., 1936, 58, 1695—1697).—Solubility data for  $\text{Na}_3\text{AlF}_6$  in aq.  $\text{Fe}^{\text{III}}$  and Al chloride, nitrate, and sulphate are recorded. Solubility is greatest in the Al salt solutions. Double salts appear to be formed. E. S. H.

**Sodium silicofluoride and aluminium fluoride, and their solubility in water and hydrofluoric acid.** N. S. NIKOLAEV, N. A. IVANOV, and S. G. KOLTIPIN (J. Appl. Chem. Russ., 1936, 9, 1183—1190).—The solubility of  $\text{Na}_2\text{SiF}_6$  and  $\text{AlF}_3\cdot 5\text{H}_2\text{O}$  (I) rises with increasing [HF] and temp. Anhyd.  $\text{AlF}_3$  is obtained by drying (I) at 300°. R. T.

**Solubility of naringin in water.** G. N. PULLEY (Ind. Eng. Chem. [Anal.], 1936, 8, 360).—Data for 6—75° are recorded. Solubility increases little with rise of temp. below 45°, but increases rapidly at >45°.

**Relative vapour pressure and aqueous solubility of the solid-solution system  $\beta$ -naphthol-naphthalene.** R. WRIGHT and N. E. WALLACE (J.C.S., 1936, 1279—1283).—The solubility of solid solutions of  $\beta\text{-C}_{10}\text{H}_7\text{-OH}$  (I) and  $\text{C}_{10}\text{H}_8$  (II) in  $\text{H}_2\text{O}$  at 25°, 65°, and 78° has been determined. At 25° the max. solubility occurs with approx. 50% (I), but at higher temp. the solubility rises with increase in the proportion of (I) until at approx. 80% it rises suddenly to the val. for pure (I). The ratio of the v.p. of (II) in solid solution to that of pure (II) is const. over definite composition ranges at 30° and 55°, indicating the presence of two solid phases in these regions, but this constancy disappears at higher temp. C. R. H.

**Laws of separation out of traces of foreign substances during crystallising out of precipitates.** N. RIEHL (Z. physikal. Chem., 1936, 177, 224—234).—Theoretical. In slow crystallisation from a supersaturated solution the ratio,  $r$ , of the micro-component (I) to the macrocomponent (II) in the crystal as a whole  $\propto$  the ratio of the concns.  $c_1$  and  $c_2$  in the solution at equilibrium. This can be explained only by supposing that in a layer of mols. deposited on the growing crystal  $r=c_1/c_2$ , at first, but subsequently this is altered by kinetic exchange between crystal and solution. For rapid crystallisation from supersaturated solution in presence of many crystal nuclei the Doerner-Hoskins equation (A., 1925, ii, 381) is valid for the relation between the initial and final vals. of  $c_1$  and  $c_2$ ; this may be explained by supposing that owing to the abnormally high solubility of the nuclei there is metastable equilibrium between the liquid and solid phases. R. C.

**Equations for diffusion of gases through metals.** W. R. HAM (Physical Rev., 1935, [iii], 47, 645). L. S. T.

**Diffusion of hydrogen through highly degassed palladium.** J. D. SAUTER and W. R. HAM (Physical Rev., 1935, [ii], 47, 645; cf. this vol., 1194).—Results obtained with highly degassed Pd are recorded. L. S. T.

**Diffusion in zeolitic solids.** M. H. HEY (Phil. Mag., 1936, [vii], 22, 492—497).—The equations derived in the kinetic theory of zeolitic diffusion previously put forward (A., 1935, 1345) are applied to analcime- $\text{NH}_3$  (I) and Pd- $\text{H}_2$  (II). The calc. diffusion const. of (I) is  $(1.2+0.7)\times 10^{-8}$  sq. cm. per sec., agreeing with the val. given by Tiselius (this vol., 153), whilst that of (II) agrees with the val. given by Jost *et al.* (A., 1935, 1200). A. J. M.

**Sorption processes on diamond and graphite. I. Reactions with hydrogen. II. Reactions of diamond with oxygen, carbon dioxide, and carbon monoxide.** R. M. BARRER (J.C.S., 1936, 1256—1261, 1261—1268).—I. Isothermals for the chemisorption of  $\text{H}_2$  by diamond (I) correspond with a large heat of sorption, the estimated val. being 58 kg.-cal. per g.-mol. compared with 45 kg.-cal. per g.-mol. for sorption by graphite. A comparison of the energy of activation-% saturation curves for (I), graphite, and charcoal indicates that only (I) approaches the ideal adsorbent which consists of perfect crystals

and for which the energy is const. for all degrees of saturation. The admission of  $O_2$  prevents the chemisorption of  $H_2$  by forming a stable oxide film on the (I).

II. At  $-78^\circ$  the sorption of  $O_2$  by (I) is nearly all physical. As the temp. is raised chemisorption becomes more pronounced, the  $O_2$  being retained as a film. At  $244-370^\circ$ , with further admission of  $O_2$ ,  $CO_2$  is liberated, and at still higher temp. the  $O_2$  film begins to decompose,  $CO_2$  and  $CO$  being formed.  $CO_2$  is reduced by (I) to  $CO$ , a small proportion of which is considered to be retained as a film.

C. R. H.

**Porosity and sorption properties of activated charcoal.** M. DUBININ and E. SAVERINA (Acta Physicochim. U.R.S.S., 1936, 4, 647-674).—A series of activated charcoals, prepared by activation of sugar-C at  $850^\circ$  and  $1000^\circ$ , has been used in the investigation of the adsorption of org. acids, PhOH, methylene-blue, Congo-red, and I from aq. solution and the data have been applied to estimate the porosity of the adsorbent. The adsorption isotherms of  $C_6H_6$  vapour at  $20^\circ$  and  $50^\circ$ , and of MeOH vapour at  $20^\circ$ , on outgassed C were determined at pressures from  $10^{-4}$  mm. to the saturation pressure. The adsorption depends on the activation process, and, for the substances used, agrees well with the Polanyi adsorption potential theory.

A. J. M.

**Activated adsorption of hydrogen and carbon monoxide on zinc oxide. Effect of water vapour.** R. L. BURWELL, jun., and H. S. TAYLOR (J. Amer. Chem. Soc., 1936, 58, 1753-1755).— $H_2O$  vapour minimises surface reduction of ZnO catalysts and is strongly adsorbed from gas mixtures by those fractions of ZnO surfaces to which the gas mixture first has access. Saturation of ZnO surfaces with  $H_2O$  vapour inhibits markedly the activated adsorption of  $H_2$  and CO.

E. S. H.

**Adsorption of iodine on quartz glass at temperatures up to  $1000^\circ$ .** P. HOLEMANN (Z. Elektrochem., 1936, 42, 680).—From the v.d. obtained by vaporisation of known amounts of I in vessels with varying areas of internal surface, the adsorption of I on fused  $SiO_2$  has been studied at  $150-1000^\circ$  and at v.d.  $1.7-3.3 \times 10^{-5}$  g. per c.c. The amount adsorbed ( $A$ )  $\propto$  the v.d. At  $150-400^\circ$  and  $850-1000^\circ$   $A \propto 1/T$ . It is concluded that for the lower temp. interval the adsorption is mol., and for the upper is at.; the heats of adsorption calc. from the proportionality factors are 1.2 and 15 kg.-cal. per g.-mol., respectively. The no. of "active centres" decreases with rising temp. and is less for at. than for mol. adsorption.

J. W. S.

**Adsorption of silver and iodide ions by freshly-precipitated silver iodide. Isoelectric point of the fresh precipitate.** I. M. KOLTHOFF and J. J. LINGANE (J. Amer. Chem. Soc., 1936, 58, 1528-1533).—The isoelectric point of freshly-pptd. AgI is  $p_{Ag}$  6.0. At the equivalence potential the excess of adsorbed  $I^-$  is 0.09% of the total I in the ppt. Adsorption of  $Ag^+$  or  $I^-$  by the fresh ppt. is in accordance with  $\Delta X - K \log C$  in the  $p_{Ag}$  range 4-7.2;  $I^-$  is more strongly adsorbed than  $Ag^+$ . The theoretical ratio

KI:Ag is found in potentiometric titration if the end-point is taken at the isoelectric point instead of at the equivalence potential, and if a correction is applied for excess of  $Ag^+$  in solution.

E. S. H.

**Adsorption of barium salts by barium sulphate from solutions in 50% ethyl alcohol.** I. M. KOLTHOFF and W. M. MACNEVIN (J. Amer. Chem. Soc., 1936, 58, 1543-1546).—Adsorption of Ba salts from 50% EtOH is  $>$  from  $H_2O$ ; the Freundlich adsorption isotherm is followed. In a series of Ba salts there is no simple relation between adsorbability and solubility.  $KBrO_3$  gives equiv. adsorption of cations and anions.  $Ca(BrO_3)_2$  is adsorbed as  $Ca(OH)BrO_3$ .

E. S. H.

**Adsorption at the interface between two fluids. II. Adsorption of five dyes at a paraffin-water and at an air-water interface.** C. W. GIBBY and C. C. ADDISON (J.C.S., 1936, 1306-1313).—No adsorption of methylene-blue (I), orange-II (II), Congo-red, Mc-orange, or Bordeaux-extra (III) at an air- $H_2O$  interface can be detected. (III) is more adsorbed on a light paraffin- $H_2O$  interface than on a  $C_6H_6$ - or a PhCl- $H_2O$  interface, the other four dyes being less adsorbed on paraffin than on  $C_6H_6$  or PhCl. The adsorption curves for (I) and (II) at all three liquid-liquid interfaces rise with the concn. and finally become horizontal. The curves for the other three dyes pass through a max. and then fall towards zero.

C. R. H.

**Adsorption of barium chloride from acidic and basic silica sols.** Z. BERESTNEVA and V. KARGIN (Acta Physicochim. U.R.S.S., 1936, 4, 675-694).—The Ba-amalgam electrode may be employed for the determination of the activity of  $Ba^{++}$  in  $SiO_2$  sols. It has been used to study the adsorption of  $Ba^{++}$  from  $BaCl_2$  solution by  $SiO_2$  sols at  $p_H$  4.7-11.4. There is no adsorption at  $p_H < 8$ . The exchange adsorption on coagulation of  $SiO_2$  sols has also been examined. The  $[Na^+]$  in alkaline  $SiO_2$  sols remains practically const. during the coagulation by  $BaCl_2$ .

A. J. M.

**Statistical mechanical treatment of adsorption phenomena of gases in organic liquids.** I, II. S. HAMAI (Sci. Rep. Tohoku, 1936, 25, 344-356, 357-363; cf. Hildebrand, this vol., 818).—I. Vals. of the const.  $b$  in Hildebrand's general solubility equation are calc. statistically and compared with those derived from experimental data. Agreement is not generally satisfactory for solutions of  $CO_2$  and  $N_2O$  in org. liquids, but solutions of  $CO_2$  in  $CS_2$  are exceptional.

II. For solutions of HCl in various org. liquids agreement is best for the more symmetrical and less polar solvents.

O. D. S.

(A) Theoretical basis of calculating work of adsorbents, in particular as applied to fractionation of mixtures of gases or vapours. M. DUBININ and S. JAVITSCH. (B) Dynamics of sorption of mixtures of vapours. M. DUBININ and M. CHRENOVA (J. Appl. Chem. Russ., 1936, 9, 1191-1203, 1204-1213).—(A) The adsorption coeff.  $\alpha$  of one vapour by another is shown theoretically to be given by  $\alpha = (C_1' - C_1)/C_2$ , where  $C_1'$  is the concn. of one vapour in the issuing air during the period

preceding appearance of the second vapour, and  $C_1$  and  $C_2$  are the initial concns. of the vapours.

(B) The above equation is shown to hold in the case of air containing EtOH and PhMe vapours passed through active C at 20°.

R. T.

**Ageing of surfaces of solutions. I. Study of variation of surface tension of solutions with time by the ring method.** K. S. G. DOSS and B. S. RAO. **II. Activated accumulation of solute molecules.** K. S. G. DOSS (Proc. Indian Acad. Sci., 1936, 4, A, 11—16, 97—107; cf. this vol., 284).—I. An automatic device for the construction of quartz helical springs is described. The spring is used for measuring the max. pull in the determination of the surface tension of PhMe by the ring method, and the effect of time has been investigated for several liquids. No consistent or reproducible variations were found and the ring method is considered to be unsuitable.

**II.** An application of the Langmuir-Adam surface pressure technique is described. A fresh surface of benzopurpurin solution shows a fall of surface tension with time; on producing mechanically an overcrowding of solute mols. in the surface, a rise of surface tension with time is found. The measured rate of accumulation of mols. at the surface is very slow and is accounted for on the basis of activated accumulation. This postulate throws light on the time variation of surface tension, the high temp. coeff., and the manifestation of surface pressure. The observations may be applied to the measurement of the efficacy of a substance as a stabiliser of foam.

N. M. B.

**Kinetics of selective wetting and surface reactions on metals in presence of electrolytes. I.** D. MRLIS and P. REHBINDER (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 123—128).—The spreading of drops of electrolyte solutions on metal plates immersed in  $C_6H_6$  has been studied by observing changes in the contact angle. Spreading is due to hydrophilisation of the surface by corrosion products accumulating at the perimeter of the drop; corrosion of the metal by the drop can thus be studied. Fatty acid in the  $C_6H_6$  phase inhibits spreading owing to adsorption on the metal surface.

A. J. E. W.

**Union with complement as a surface reaction.**

**I. Surface tension and adsorption. Model experiments with caffeine solutions.** F. SEELICH (Biochem. Z., 1936, 286, 396—407).—Curves show the surface tension at various  $H_2O$ -non-miscible org. substance (paraffin,  $C_6H_6$ ,  $NPhMe_3$ , oleic acid, etc.) interfaces when varying amounts of caffeine are added and the relation between surface tension and adsorption is investigated. The bearing of the observations on biological surface reactions is discussed.

P. W. C.

**Studies of unimolecular films by the ripple method. I, II.** J. SAMESHIMA and T. SASAKI (Bull. Chem. Soc. Japan, 1936, 11, 539—546, 547—552).—I. The relation between mol. area and amplitude of ripple has been determined by the const. surface area method for palmitic (I), stearic, myristic (II), and oleic acids (III), tetradecyl alcohol (IV), and palmitonitrile (V), and the results are in agreement with surface pressure data. The damping action

of the film increases with the vibration frequency of the wave-source (tuning fork), in accordance with hydrodynamical theory. It is suggested that the damping action of oil on ocean waves is due to the subsidence of ripples, entailing a diminution in the resistance to the wind.

**II.** Oleic and lauric acids, (I)—(V) tripalmitin, triolein, ricinoleic acid, and Et palmitate have been studied using const. oil quantity and varying surface area. The compression and expansion curves show hysteresis with an acid medium, which is attributed to inclination of the mols. in the expanded state. The mol. wt. of mastic, calc. from the area at which the ripples subside, is approx. 3600.

R. S.

**Multimolecular films.** W. D. HARKINS and R. J. MYERS (J. Amer. Chem. Soc., 1936, 58, 1817—1819).—Multimol. liquid films of stearic, oleic, myristic, and pentadecic acid have been obtained by thickening the films with a liquid paraffin (nujol) of low volatility.

E. S. II.

**Contact potentials of reversible soluble films of lauric acid.** R. T. FLORENCE, R. J. MYERS, and W. D. HARKINS (Nature, 1936, 138, 405—406).—The changes in surface pressure and in the contact potential when the surface of a solution of lauric acid is swept clean of its adsorbed film and the acid allowed to accumulate at the surface by diffusion from the interior of the solution have been determined. The results indicate the importance of the time factor in the determination of  $\gamma$  for solutions of surface-active materials, and the unsuitability of dynamic methods for materials which require considerable time for equilibrium in the surface.

L. S. T.

**Electrical properties of films of  $\omega$ -bromohexadecic acid.** M. GEROVICH and A. FRUMKIN (J. Chem. Physics, 1936, 4, 624).—Films of the acid on the surface of a solution containing 0.01N-KCl and  $10^{-4}$ N-HCl show a large negative interfacial potential owing to the orientation of C-Br linkings. By increasing the acidity of the solution to  $10^{-3}$ N-HCl, the surface pressure is decreased markedly and the potential is changed to a small positive val. probably owing to a change of film structure.

J. G. A. G.

**Unimolecular layers of chlorophyll.** W. SJOERDSMA (Nature, 1936, 138, 405).—A 3:1 mixture of the *a* and *b* modifications forms unimol. layers on  $H_2O$ , 0.01N- and 0.1N- $H_2SO_4$ . The limiting area per mol. at zero compression is  $124 \text{ \AA}^2$ , and at 26 dynes per cm. the film becomes multimol. On  $H_2O$  in equilibrium with  $CO_2$  at atm. pressure the mols. appear to require more space, the limiting area being  $132 \text{ \AA}^2$ . NO has no such effect.

L. S. T.

**Permeability of membranes. III. Ionic permeability of non-aqueous liquid layers.** K. H. MEYER, H. HAUPTMANN, and J. F. SIEVERS. **IV. Analysis of structure of vegetable and animal membranes.** K. H. MEYER and J. F. SIEVERS (Helv. Chim. Acta, 1936, 19, 948—962, 987—995; cf. this vol., 1065).—III. Diffusion potentials across layers of  $NH_2Ph$ ,  $PhOH$ , *m*-cresol, and  $CH_3Bu^aOH$  have been measured at 20° and the mobilities of the participating ions calc. Diffusion is determined by

the mobilities and solubilities of the ions in the non-aq. liquid and there is no selectivity. Partition coeffs. of ions have been determined potentiometrically and published data are discussed.

IV. Diffusion potentials between KCl solutions across vegetable (bracts of *Iris amoena*) and animal (skin of *Bombinator igneus*) membranes have been measured. The former contains acids of high mol. wt. and is permeable to cations, whilst the latter shows only slight permeability. These, and similar data relating to membranes studied by other workers, are used to elucidate their structure. Accumulation of K<sup>+</sup> in plants is not due to selective solubility in lipins, but to its greater facility of passage through what is essentially a fine-meshed sieve. F. L. U.

Statistical evaluation of sieve constants in ultrafiltration. J. D. FERRY (J. Gen. Physiol., 1936, 20, 95—104).—The sieve const. is evaluated in terms of the calibrated membrane porosity and the particle size. H. G. R.

Viscosity nomograph for salt solutions. D. S. DAVIS (Chem. Met. Eng., 1936, 43, 485).—A nomograph from which  $\eta$  at 25° of 0.1—1.0*N* solutions of 38 salts can be read is published. W. L. D.

Viscosity of dilute solutions: technique and measurements with solutions of hydrocarbons. K. H. MEYER and A. VAN DER WYK (Kolloid-Z., 1936, 76, 278—289).—Systematic errors and the corresponding corrections in the determination of  $\eta$  of dil. solutions are discussed. The sp.  $\eta$  of dil. (<1%) solutions of higher hydrocarbons in CCl<sub>4</sub> has been determined with special reference to changes in constitution, concn., and temp. In these series  $\eta$  is not a function of the length of the dissolved mol., but varies in a complicated way with constitution. The variation of  $\eta$  with temp. and concn. shows that the dissolved mols. cannot be regarded as rod-like particles. E. S. H.

High-frequency loss and molecular properties of polar solutions. G. MARTIN (Physikal., 1936, 37, 665—667).—The high-frequency loss for dil. solutions of polar substances in non-polar solvents has been determined in order to verify the dipole theory of high-frequency loss. The dielectric loss for *o*-, *m*-, and *p*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>  $\propto \mu^2$ , as required by theory. The extrapolated loss at infinite dilution for Pr<sup>o</sup>OH, *n*-C<sub>8</sub>H<sub>17</sub>·OH, and *n*-C<sub>16</sub>H<sub>33</sub>·OH increases with the no. of C in the mol. The effect of  $\eta$ , investigated for solutions of *o*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> in C<sub>6</sub>H<sub>14</sub>, C<sub>6</sub>H<sub>6</sub>, CCl<sub>4</sub>, and decalin, the relaxation time being plotted against  $\eta$ , shows that Stokes' law holds in the calculation of relaxation time even for particles of mol. size, if an inner  $\eta$  is assumed, which differs from that determined by macroscopic methods. In non-polar liquids this mol. is a function of the ordinary  $\eta$  and the mol. vol. A. J. M.

Interdiffusion of acid and base in aqueous solution. C. V. KING and W. H. CATHCART (J. Amer. Chem. Soc., 1936, 58, 1639—1642).—Diffusion coeffs. of HCl and NaOH in presence of NaCl have been determined over a wide concn. range. In the interdiffusion of HCl and NaOH in aq. NaCl the diffusion coeffs. are unchanged if sufficient NaCl is present

initially; in the porous-disc cell the diffusion rates are increased since the concn. gradients become sharper because of neutralisation within the disc. Limitations of the porous-disc cell are demonstrated. E. S. H.

Diffusion of magnesium chloride and nitrate in aqueous solution. L. W. ÖHOLM (Finska Kem. Medd., 1936, 45, 71—76).—Diffusion data are compared with vals. for other properties of the solutions. M. H. M. A.

Viscosities and densities of dilute aqueous solutions of weak electrolytes (*o*-nitrobenzoic acid). A. BANCHETTI (Annali Chim. Appl., 1936, 26, 351—356).— $d$  varies almost linearly with the concn. ( $c$ ) and the variation of  $\eta$  is given by  $\eta - 1 = ac^b$ , where  $a$  and  $b$  are consts. L. A. O'N.

Condition of electrolytes in aqueous solutions. A. H. W. ATEN (Chem. Weekblad, 1936, 33, 555—562).—A lecture. S. C.

Physical characterisation of dissolved ions. II. F.p. and conductivity of very dilute aqueous solutions of alkali halides. J. LANGE (Z. physikal. Chem., 1936, 177, 193—212; cf. A., 1934, 596).—The f.p. and conductivity of solutions of the chlorides and iodides of Li, Cs, and K at 0.001—0.1*N* have been determined. Up to 0.05*N* the results can be expressed by  $1 - f_0 = 0.37\sqrt{c} + B_0c$  (f.p.) and  $1 - f_\infty = (0.219 + 29.5/\Delta_0)\sqrt{c} + B_\infty c$  (conductivity). For all the salts  $B_0$  and  $B_\infty$  are negative and approx. equal, indicating complete dissociation. Each consists essentially of a negative and a positive component. The negative component arises from the finite size of the ions in the sense of the Debye-Hückel theory, varies little from one ion to another, and has the same val. for  $B_0$  as for  $B_\infty$ . The positive component originates in the mutual attraction of the ions owing to the short-period perturbations of the movements of the electrons, on the lines of London's theory (A., 1931, 149), and can be approx. calc. by means of this theory; it is greater for  $B_\infty$  than for  $B_0$ . R. C.

Hydrochloric and hydrobromic solutions of the salts of cobalt, copper, and bivalent nickel. P. JOB (Ann. Chim., 1936, [xi], 6, 97—144; cf. A., 1935, 582).—Solutions of salts of Co, Cu, and Ni in aq. HCl, HBr, and NaBr have been studied spectrographically. For the Co solutions the absorption is independent of the anion and  $\propto [\text{Co}^{2+}]$  for a fixed concn. of acid. The  $\lambda$ - and [HCl]-absorption curves show max., whilst the absorption becomes const. when [HCl] > 13 mols. per litre. The results can be accurately reproduced on the assumption that an intermediate complex CoCl<sup>+</sup> and a blue complex CoCl<sub>2</sub><sup>+</sup> are formed. HBr solutions show similar properties, the blue colour appearing, however, at a slightly greater concn. The absorption of Cu<sup>2+</sup> in aq. HBr increases with the [HBr] to a limiting val. at 10 mols. per litre. Two complexes CuBr<sup>+</sup> and CuBr<sub>2</sub><sup>+</sup> are probably formed. The activity coeffs. of NaBr, determined by comparison of the absorption of NaBr and HBr solutions containing Cu<sup>2+</sup>, agree with the results of Harned and Douglas. Solutions of Ni<sup>2+</sup> in HBr resemble those of Co<sup>2+</sup> in HBr and contain the coloured complexes NiBr<sub>2</sub><sup>+</sup> and NiBr<sub>4</sub><sup>2-</sup>. The equilibrium consts. have been calc. in each case and the stabilities of the

complexes compared.  $\text{CuBr}'$  is more stable than  $\text{CoBr}'$ , whilst  $\text{CoBr}_3'$  is less stable than  $\text{CoCl}_3'$ .

R. S.

**Molecular state of red rhenium chloride in solution.** F. W. WRIGGE and W. BILTZ (*Z. anorg. Chem.*, 1936, 228, 372—382).—The mol. wt. of anhyd.  $\text{ReCl}_3$  (prepared by sublimation in a vac.), calc. from the depression of the f.p. of  $\text{AcOH}$ , corresponds with  $\text{Re}_3\text{Cl}_6$ . The dialysis coeff. of its  $\text{HCl}$  solutions indicates that it exists as  $\text{HReCl}_4$  in these solutions. The absorption spectrum of anhyd.  $\text{ReCl}_3$  in  $\text{AcOH}$ , dioxan,  $\text{H}_2\text{SO}_4$ , or  $\text{HCl}$  has a max. at about 5100 Å., and a min. at about 4500 Å. Solutions of  $\text{ReCl}_3 \cdot 2\text{H}_2\text{O}$  (obtained by exposure of  $\text{ReCl}_3$  to moist air) in  $\text{AcOH}$  or dioxan show two absorption max. at about 5000 and 5400 Å., respectively. The structures of the anhyd. and hydrated salts are discussed. J. W. S.

**Light pressure and Brownian movement.** M. SATO (*Sci. Rep. Tohoku*, 1935, 28, 156—162).—The results obtained for the light pressure and mean square of the displacement of a Brownian particle from Planck's radiation law are in good agreement with those derived from Glaser's theory of corpuscular gas (cf. *Z. Physik.*, 1935, 94, 677). A. R. P.

**Rheopexy in bentonite.** E. A. HAUSER and C. E. REED (*J. Amer. Chem. Soc.*, 1936, 58, 1822).—Fractionation (by high-speed centrifuge) of dispersions of bentonite in  $\text{H}_2\text{O}$  gives completely amicromic fractions which exhibit rheopexy (A., 1935, 933). H. B.

**Behaviour of aerosols in the acoustic field. II. Behaviour of suspended matter in oscillating gases at sonic and ultra-sonic frequencies.** O. BRANDT (*Kolloid-Z.*, 1936, 76, 272—278; cf. this vol., 794).—The rate of aggregation of the particles (0.2—1.7  $\mu$  diameter) in stationary and streaming aerosols of liquid paraffin has been determined for different frequencies by measurement of the rate of fall of the particles and by optical means.

E. S. H.

**Effect of an electric field on the intensity of the Tyndall light for different forms of colloidal particles.** H. UERLINGS (*Physikal. Z.*, 1936, 37, 655—657).—The effect of an electric field on the Tyndall light from  $\text{V}_2\text{O}_5$ , blue Au, benzopurpurin, and  $\text{Fe}(\text{OH})_3$  sols (all having non-spherical particles) and from Ag, red Au, and mastic sols (with spherical particles) has been examined. The electric field increases the intensity of the light for the former group of sols when the lines of force and the direction of vibration of the electric vector coincide, and the direction of observation is mutually perpendicular to this, and to the direction of the incident light. Sols with spherical particles show no increase in the intensity of the Tyndall light on application of the field.

A. J. M.

**Structures and forces in colloidal systems.** H. FREUNDLICH (*Proc. Roy. Inst.*, 1936, 29, 232—252).—A lecture.

**Relations between molecular size, statistical molecular structure, and elastic properties of highly-polymerised substances.** W. KUHN (*Kolloid-Z.*, 1936, 76, 258—271; cf. this vol., 785).—Theoretical.

E. S. H.

**Determination of the specific weights of cellulose solutions. Estimation of the specific weights of the double compounds of cellulose derivatives with organic solvents.** W. KUMICHEL and C. TROGUS (*Cellulosechem.*, 1936, 17, 97—102).—From *d* measurements of solutions of cellulose nitrates in  $\text{COMe}_2$  and in 4-methylcyclohexanone (I) the sp. vols. of the compounds have been estimated. The vals. found agree with those given by *X*-ray measurements if the unit cell in  $\text{COMe}_2$  contains 10  $\text{C}_6$  units, whilst that in (I) contains 6  $\text{C}_6$  units and 6 mols. of solvent (at 20—30°) and 10  $\text{C}_6$  units and 20 mols. of solvent (at 18°).

A. G.

**Lyophilic colloids. III. Micelle composition.** H. KROEPFELIN (*Rev. Fac. Sci. Univ. Istanbul*, 1936, 1, 70—76).— $\text{Et}_2\text{O}$  solutions of rubber show an increased Tyndall effect on addition of small amounts of  $\text{EtOH}$  or  $\text{COMe}_2$  contrary to the theory which is presented. The Tyndall effect increases more slowly than the concn.

R. S.

**Colloid synthesis by vapour explosions and the colloid-chemical investigation of the disperse systems obtained.** N. SATA (*Bull. Chem. Soc. Japan*, 1936, 11, 481—503; cf. this vol., 1198).—Dust, burnt cork, and passage through filter-paper stabilise the Hg sol obtained by the vapour explosion method.  $\text{Na}_2\text{SO}_3$  coagulates the sol whilst the stability increases to a max. with increasing  $[\text{Na}_2\text{S}]$  owing to the formation of stabilising complexes. A similar stability max. obtained with  $\text{NaI}$  is ascribed to the formation of  $\text{HgI}$ , which gives a green colour in presence of Hg. The concn. range of stabiliser giving max. stability is diminished by irradiation with ultra-violet light, and more so in the case of  $\text{Na}_2\text{S}$  than  $\text{NaI}$ . Se sols have been prepared by the vapour explosion method and the influence of stirring and shaking investigated.  $\text{O}_2$  increases the stability of the sol by reacting with adsorbed  $\text{SeH}_2$ . S sols, similarly prepared, are unstable.

R. S.

**Coagulation of colloids. XIV. Coagulation of colloidal arsenious sulphide by mercuric chloride. Inadmissibility of viscosity and transparency as general criteria of coagulation.** S. S. JOSHI and S. S. KULKARNI (*J. Indian Chem. Soc.*, 1936, 13, 439—447; cf. this vol., 795).—No over-all change of *n* or opacity is observed during coagulation by  $\text{HgCl}_2$ , although normal variations in these properties occur during coagulation by  $\text{CdCl}_2$  or  $\text{KCl}$ . These properties do not depend only on the charge, shape, and size of the disperse particles, but on macroscopic properties of the system as a whole.

E. S. H.

**Variation of cataphoretic velocity of colloidal particles during coagulation. II.** J. N. MUKHERJEE, S. G. CHAUDHURY, and J. SEN-GUPTA (*J. Indian Chem. Soc.*, 1936, 13, 428—438; cf. this vol., 1201).—The variation of electrophoretic velocity with time has been determined for sols of  $\text{As}_2\text{S}_3$ ,  $\text{V}_2\text{O}_5$ , Se,  $(\text{UO}_2)_2\text{Fe}(\text{CN})_6$ ,  $\text{Cu}_2\text{Fe}(\text{CN})_6$ , and  $\text{Fe}(\text{OH})_3$  in presence of various electrolytes. The % increase of velocity is the greater the higher are the concn. of the pptg. electrolyte and the valency of the pptg. ion. The effect also depends on the nature of the sol and of the electrolyte and on the electrolyte content of the

sol and thus runs parallel with the effect on the rate of coagulation. E. S. H.

**Ionic interchange in stearic acid sols and the mechanism of coagulation.** T. R. BOLAM and A. I. S. DUNCAN (J.C.S., 1936, 1317—1324).—The coagulation of stearic acid (I) by  $\text{H}_2\text{SO}_4$  and sulphates has been followed; the coagulative effect decreases in the order  $\text{H}_2\text{SO}_4$ ,  $\text{MgSO}_4$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{Li}_2\text{SO}_4$ . The  $\text{H}^+$  liberated from (I) by ionic interchange increases with increasing salt concn., the tendency of the cations to displace  $\text{H}^+$  being  $\text{Mg}^{++} > \text{K}^+ > \text{Na}^+ > \text{Li}^+$ . The data support the view that the surface mols. of (I) particles dissociate like a weak acid. C. R. H.

**Liesegang rings in non-gelatinous media.** II. V. GORE (Kolloid-Z., 1936, 76, 330—333; cf. this vol., 1201).—The formation of periodic structures by diffusion of an electrolyte into sols of metal hydroxides, peptised by another electrolyte, is described. The results support the periodic-coagulation theory.

E. S. H.

**Sensitising effect of small amounts of alkali on silicic acid sol.** V. N. KRESTINSKAJA and N. E. NATANSON (Kolloid-Z., 1936, 76, 313—321).—Experiments on coagulation with  $\text{NaCl}$  and titration with  $\text{HCl}$  show that small amounts of  $\text{NaOH}$  produce complex silicates, which sensitise the sol to electrolyte coagulation, but with increasing amounts of  $\text{NaOH}$  the product is  $\text{Na}_2\text{SiO}_3$ , which stabilises the sol.

E. S. H.

**Oxidation and reduction reactions of colloidal substances.** IV. Theory of structure of aggregates of colloid particles. V. N. SKVORZOV (Kolloid-Z., 1936, 76, 322—330; cf. A., 1935, 1208).—The rate of reaction of mono- and poly-disperse sols of  $\text{MnO}_2$  and  $\text{Mn}_2\text{O}_3$  with  $\text{H}_2\text{C}_2\text{O}_4$  and  $\text{H}_2\text{SO}_4$  has been determined. From the results it is inferred that the disperse particles have a zonal structure. Practically monodisperse Mn oxide sols can be prepared by inoculation with a nuclear Au sol.

E. S. H.

**Colloidal potassium complexes.** R. KELLER (Kolloid-Z., 1936, 76, 334—337).—The physiological effects of  $\text{K}^+$  and combined K in a negatively-charged colloid are contrasted.

E. S. H.

**Molecular and colloid solubility of acid and salt dyes, especially benzopurpurin.** I. Dissolution of acid dyes in sodium hydroxide. W. O. OSTWALD and R. WALTER (Kolloid-Z., 1936, 76, 291—313).—Benzopurpurin acid is shown by X-ray analysis to be microcryst.; the crystallites are of about colloid dimensions. The solubility of the dye acid in aq.  $\text{NaOH}$  is in accordance with the solid-phase rule, reaching a max. for medium amounts of the dye. With increasing  $[\text{NaOH}]$  the max. is displaced in the direction of increased solubility and increased amount of solid phase. Dissolution by salt formation occurs only when excess of  $\text{NaOH}$  is present.

E. S. H.

**Swelling pressure and van der Waals force.** G. V. SCHULZ (Naturwiss., 1936, 24, 589; cf. A., 1932, 225, 570).—The dependence of the consts.  $k$  and  $v$  in  $p = ks^v$  ( $p$  is swelling pressure, and  $s$  is swelling vol.) on the dispersion medium, and their independence of the mol. wt. of the solute make it probable that

swelling and the co-vol. of substances in solution are related to the van der Waals forces between solvent and solute. Assuming this to be true, it is possible to calculate the val. of the force, and a quant. law of force is derived by employing solvation potentials.

A. J. M.

**Syneresis.** III. G. ROSSI and G. SCANDELLARI (Gazzetta, 1936, 66, 459—464; cf. this vol., 935).—The liquid resulting from the syneresis of agar-agar gels containing non-electrolytes is more conc. with respect to these substances than the original gel. The results are discussed.

O. J. W.

**Molecular state of proteins in mixtures and concentrated solutions.** K. O. PEDERSEN (Nature, 1936, 138, 363).—The addition of a protamine (clupein) to serum-albumin lowers the sedimentation const., probably owing to dissociation into mols. of one eighth the original size. Haemoglobin is also dissociated in presence of other proteins and clupein.

L. S. T.

**Denaturation and hydration of proteins.**—See this vol., 1404.

**Limiting high-temperature rotational partition function of non-rigid molecules.** VI. The methanol equilibrium. L. S. KASSEL (J. Chem. Physics, 1936, 4, 493—496).—The entropy of  $\text{MeOH}$  and the equilibrium const. for  $\text{MeOH}$  synthesis are calc. for two mol. models: (i) with free rotation around the  $\text{CO}$  linking and (ii) with a torsional oscillation of frequency  $700 \text{ cm}^{-1}$  about that linking. The evidence favours (ii) but does not exclude (i).

J. G. A. G.

**Thermal separation of gas mixtures and its significance in the measurement of chemical equilibria; measurement data for the systems  $\text{H}_2$ - $\text{H}_2\text{S}$  and  $\text{Ag}$ - $\text{S}$ - $\text{H}$ .** N. G. SCHMAHL and W. KNEPPER (Z. Elektrochem., 1936, 42, 681—686).—A thermal diffusion effect has been observed with  $\text{H}_2$ - $\text{H}_2\text{S}$  mixtures, the effect increasing with increasing temp. difference between different parts of the container and with increasing pressure. The effect at  $20^\circ$  and  $400^\circ$  is a max. with about 40%  $\text{H}_2\text{S}$  and amounts to about 6% difference in  $[\text{H}_2\text{S}]$  between the two regions. Errors which may be introduced in the measurement of thermal equilibria of gases and solids when portions of the vessels are at different temp. are emphasised. Measurements on the equilibrium  $2\text{Ag} + \text{H}_2\text{S} \rightleftharpoons \text{Ag}_2\text{S} + \text{H}_2$ , corr. for this effect, indicate that discrepancies previously encountered are associated with the use of  $\text{Ag}$  in thread and powder form, and that these differ in heat content by  $153.1 \text{ g.-cal. per atom}$ .

J. W. S.

**Theory of concentrated solutions.** XIII. Aqueous solutions of organic compounds. M. EWERT (Bull. Soc. chim. Belg., 1936, 45, 493—515).—Partial v.p.-composition data are recorded for mixtures of 16 org. liquids with  $\text{H}_2\text{O}$ , and are used in calculating activity coeffs. The data are discussed on the basis of thermodynamic theory.

H. J. E.

**Isotope exchange between water and some organic compounds.** M. HARADA and T. TITANI (Bull. Chem. Soc. Japan, 1936, 11, 465—474).—From experiments with org. compounds it is con-

cluded that the isotopic replacement of D atoms occurs only when these are linked to O or N. No replacement was observed with  $\text{CHCl}_3$ ,  $\text{Et}_2\text{O}$ , and  $\text{PhCHO}$ . For the remaining compounds the distribution quotients, *i.e.*, the ratios between the at. concn. of D in the total exchangeable H in the compound, and the at. concn. of D in the total H in the  $\text{H}_2\text{O}$ , were  $\text{NH}_2\text{Ph}$ , 1.11;  $\text{PhOH}$ , 1.07; pyrrole, 0.88;  $\text{BzOH}$ , 1.0;  $\text{CH}_2\text{Ph}\cdot\text{OH}$ , 1.10. C. R. H.

Isotopic exchange between aniline hydrochloride and heavy water. M. HARADA and T. TITANI (Bull. Chem. Soc. Japan, 1936, 11, 554—556).—The equilibrium  $\text{NH}_2\text{PhCl} + 3\text{D}_2\text{O} \rightleftharpoons \text{C}_6\text{H}_5\text{D}_3\cdot\text{ND}_3\text{Cl} + 3\text{H}_2\text{O}$  is established at  $60^\circ$  after 3 hr. Replacement of the H of  $\text{NH}_2\text{PhCl}$  occurs immediately, but when  $\text{ND}_3\text{PhCl}$  is heated alone to  $160^\circ$ , D wanders into the nucleus. R. S.

Properties of pentadeuterobenzoic acid,  $\text{C}_6\text{D}_5\cdot\text{CO}_2\text{H}$ . H. ERLIENMEYER and A. EPPRECHT (Nature, 1936, 138, 367).—Vals. recorded are  $K^{25}_{25}$   $6.6 \times 10^{-5}$ , mol. heat of combustion 761,380 g.-cal., and solubility 0.34 g. per 100 c.c. of  $\text{H}_2\text{O}$  at  $18^\circ$ . L. S. T.

Primary and secondary dissociation constants of malonic, succinic, and glutaric acids by potentiometric titration. W. L. GERMAN and A. I. VOGEL (J. Amer. Chem. Soc., 1936, 58, 1546—1549).—Data obtained at  $25^\circ$ , using the quinhydrone electrode, are recorded. The calc. primary dissociation consts. agree within 2—4% with those determined by conductivity. E. S. H.

Ionisation constant of hydrazinium hydroxide. G. C. WARE, J. B. SPULNIK, and E. C. GILBERT (J. Amer. Chem. Soc., 1936, 58, 1605—1606).—Ionisation consts. of  $\text{N}_2\text{H}_5^+$  as an acid and of  $\text{N}_2\text{H}_5\text{OH}$  as a base have been determined at  $15^\circ$ ,  $25^\circ$ , and  $35^\circ$  with the aid of the glass electrode. E. S. H.

Polyhalides. IV. Formation and dissociation of polyhalides of ammonium and substituted ammonium bases. S. K. RAY and R. R. BHATTACHARYA (J. Indian Chem. Soc., 1936, 13, 456—463; cf. A., 1934, 599).—The conditions of formation and dissociation of  $\text{NH}_4\text{ClBr}_2$ ,  $\text{NH}_4\text{ClI}_2$ ,  $\text{NH}_4\text{BrI}_2$ ,  $\text{NH}_4\text{Br}_3$ ,  $\text{NH}_4\text{I}_3$ ,  $\text{NMe}_4\text{I}_3$ , and  $\text{C}_5\text{H}_5\text{NEtBrI}_2$  in aq. media and the solubility of I in  $\text{NEt}_4\text{I}$ ,  $\text{NEt}_4\text{Br}$ , and  $\text{C}_5\text{H}_5\text{NEtI}$  and of Br in  $\text{NEt}_4\text{Br}$  and  $\text{C}_5\text{H}_5\text{NEtBr}$  at  $25^\circ$  or  $30^\circ$  have been determined. The degree of dissociation of  $\text{NEt}_4\text{Br}$  at  $25^\circ$  and of  $\text{C}_5\text{H}_5\text{NEtBr}$  at  $30^\circ$  has been calc. from conductivity measurements. E. S. H.

Equilibrium between isopropyl alcohol and acetone in presence of alcohol-dehydrogenase. Oxido-reduction potential of the system  $\cdot\text{CH}(\text{OH})\cdot \rightleftharpoons \cdot\text{CO}\cdot$ . R. WURMSER and S. FILITTI-WURMSER (J. Chim. phys., 1936, 33, 577—586; cf. this vol., 936).—The attainment of equilibrium has been followed potentiometrically from both sides. It is shown, by comparison of the normal potential  $E_0$  with that of other  $\cdot\text{CH}(\text{OH})\cdot$   $\cdot\text{CO}\cdot$  systems, that introduction of  $\cdot\text{CO}$  into  $\text{Pr}^\beta\text{OH}$  increases  $E_0$  by +0.078 volt, whereas  $E_0$  decreases as the ratio  $\text{NH}_2/\text{CO}$  increases. R. S.

Equilibrium constants in terms of activities (cryoscopic). V. *p*-Toluidine *o*-chlorophenoxide and *p*-chlorophenoxide in benzene and in *p*-dichlorobenzene. W. R. BURNHAM and W. M. MADGIN (J.C.S., 1936, 1303—1306).—The activity coeffs. for  $\text{C}_6\text{H}_6$  and  $\text{p-C}_6\text{H}_4\text{Cl}_2$  solutions of the undissociated complexes *p*-toluidine *o*- (I) and *p*-chlorophenoxide (II) at concns. up to 0.05 mol. have been determined cryoscopically. The average vals. for the dissociation consts. are 20.95 and 8.66 for (I) and 48.39 and 16.54 for (II) in  $\text{C}_6\text{H}_6$  and  $\text{p-C}_6\text{H}_4\text{Cl}_2$ , respectively. Each complex is formed exothermally, the heats of formation being —4200 g.-cal. for (I) and —3500 g.-cal. for (II). In discussing dipolar influences and chelation the vals. have been compared with those previously obtained for similar phenol-base complexes. C. R. H.

Alkali-hydrolysis and dissociation constants of diketopiperazines and aniline peptides. M. ODA (J. Biochem. Japan, 1936, 23, 241—266).—The rates of hydrolysis of diketopiperazines (I) or  $\text{NH}_2\text{Ph}$  peptides by 0.5*N*-NaOH are not related to the corresponding rates of enzymic hydrolysis. Electrometric titration indicates that (I) which are hydrolysed by carboxypolypeptidase exist at  $p_H$  8 as negatively-charged anions; this probably facilitates formation of enzyme-substrate complexes. Basic and, for the last three, acidic dissociation consts. are given for glycol derivatives of  $\text{NH}_2\text{Ph}$ , *o*- $\text{C}_6\text{H}_4\text{Me}\cdot\text{NH}_2$ , *p*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NH}_2$ , and *o*-, *m*-, and *p*- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . F. O. H.

Dissociation pressure of magnesium chloride hexahydrate. K. SANO (Sci. Rep. Tôhoku, 1936, 25, 184—186).—Dissociation pressures of  $\text{MgCl}_2\cdot 6\text{H}_2\text{O}$  between  $50^\circ$  and  $110^\circ$  are given by  $\log P_{\text{H}_2\text{O}} = 3473.25/T + 11.2195$ . For  $\text{MgCl}_2\cdot 6\text{H}_2\text{O} = \text{MgCl}_2\cdot 4\text{H}_2\text{O} + 2\text{H}_2\text{O}$ .  $\Delta H_{298} = 32146$  g.-cal.,  $\Delta F_{298} = 9070$  g.-cal., and  $\Delta S_{298} = 77.44$  e.u. O. D. S.

Dissociation pressure of copper sulphate pentahydrate. F. SCHACHERL and O. BĚHOŮNEK (Nature, 1936, 138, 406; this vol., 1070).—Dissociation pressures of  $\text{CuSO}_4\cdot 5\text{D}_2\text{O}$  at  $20^\circ$ ,  $30^\circ$ ,  $40^\circ$ ,  $50^\circ$ , and  $60^\circ$  are 4.4, 9.9, 21.0, 42.1, and 80.9 mm., respectively. L. S. T.

Thermal transitions of copper sulphate pentahydrate: molecular rotation and the dehydration of hydrates. T. I. TAYLOR and H. P. KLUG (J. Chem. Physics, 1936, 4, 601—607).—The heating curve of  $\text{CuSO}_4\cdot 5\text{H}_2\text{O}$  (I) from  $-75^\circ$  to  $160^\circ$  has been determined by a differential thermocouple method at 690 mm. Small abrupt changes in heat capacity shown at  $29^\circ$ ,  $35^\circ$ , and  $53.7^\circ$  are attributed to a change from oscillatory to rotational movement of the  $\text{H}_2\text{O}$  mols. in the crystal. Dehydrations at  $96.5^\circ$ ,  $102^\circ$ , and  $113^\circ$  correspond with the formation of the tetra-, tri-, and mono-hydrates, respectively. A view of the mechanism of dehydration of (I) by heat, based on mols. acquiring sufficient vibrational-rotational energy to break from the crystal lattice, is shown to accord with the cryst. structure (cf. A., 1934, 1296). J. G. A. G.

System calcium oxide-ferric oxide. B. TAVASCI (Annali Chim. Appl., 1936, 26, 291—300).—The system has been studied micrographically and the

results compared with those of Sosman and Merwin (A., 1916, ii, 618). The existence of  $2\text{CaO} \cdot \text{Fe}_2\text{O}_3$  and  $\text{CaO} \cdot \text{Fe}_2\text{O}_3$ , and the decomp. of the latter at  $1216^\circ$  are confirmed, but  $\text{CaO} \cdot 2\text{Fe}_2\text{O}_3$ , decomp. at  $1227^\circ$  into  $\text{Fe}_2\text{O}_3$  + liquid, is also found. The eutectic, m.p.  $1203^\circ$ , has the approx. composition  $3\text{CaO} \cdot 4\text{Fe}_2\text{O}_3$  and consists of a mixture of  $\text{CaO} \cdot \text{Fe}_2\text{O}_3$  and  $\text{CaO} \cdot 2\text{Fe}_2\text{O}_3$ .  
L. A. O'N.

**System potassium dichromate-sodium dichromate.** A. LEHRMAN, H. SELDITCH, and P. SKELL (J. Amer. Chem. Soc., 1936, 58, 1612—1615).—The liquidus curve is of the simple eutectic type.  $\text{Na}_2\text{Cr}_2\text{O}_7$  has m.p.  $356.7 \pm 1.0^\circ$ . The transition point of  $\text{K}_2\text{Cr}_2\text{O}_7$  has been redetermined as  $241.6 \pm 1.0^\circ$ .  
E. S. H.

**System  $\text{Zn}[\text{Hg}(\text{CNS})_4]$ - $\text{Cu}[\text{Hg}(\text{CNS})_4]$ .** M. STRAUMANIS and E. ENCE (Z. anorg. Chem., 1936, 228, 334—340).— $\text{Zn}[\text{Hg}(\text{CNS})_4]$  forms a continuous series of mixed crystals with  $\text{Cu}[\text{Hg}(\text{CNS})_4]$  from solutions with a  $\text{Cu}:\text{Cu}+\text{Zn}$  ratio  $> 38.5\%$ . The  $\text{Zn}[\text{Hg}(\text{CNS})_4]$  crystal lattice is expanded proportionately to the  $[\text{Cu}]$ . On crystallising mixtures with  $\text{Cu}:\text{Cu}+\text{Zn}$  ratios  $> 40\%$ , green crystals of  $\text{Cu}[\text{Hg}(\text{CNS})_4]$ , free from Zn, are also obtained.  
J. W. S.

**Solid-liquid equilibria in systems of organic components. V. Systems consisting of *o*-, *m*-, and *p*-aminophenol.** K. HRYNAKOWSKI and M. SZMYT (Z. physikal. Chem., 1936, 177, 306—316).—The f.-p. diagrams of the ternary and three binary systems have been obtained. *p*- and *m*-Aminophenol combine in equimol. proportions to form an incongruently melting compound. Activity coeffs. in the melts have been calc. The mol. attractive forces increase in the order *o*- < *m*-aminophenol.  
R. C.

**Ternary systems. XXI. Lead nitrate, ammonium nitrate, and water at  $25^\circ$ .** A. E. HILL and N. KAPLAN (J. Amer. Chem. Soc., 1936, 58, 1644—1645).—The solubility of  $\text{Pb}(\text{NO}_3)_2$  is increased by  $\text{NH}_4\text{NO}_3$ , but < by  $\text{KNO}_3$ . No double salts have been found as solid phases.  
E. S. H.

**Systems  $\text{MCl}_2$ - $\text{HCl}$ - $\text{H}_2\text{O}$ . II. System  $\text{CdCl}_2$ - $\text{HCl}$ - $\text{H}_2\text{O}$ .** D. I. KUZNETZOV and A. A. KOSHUCHOVSKI (J. Appl. Chem. Russ., 1936, 9, 1178—1182).—Solubility data are recorded for  $25^\circ$ . The solid phases are  $\text{CdCl}_2 \cdot \text{H}_2\text{O}$  and  $2.5\text{H}_2\text{O}$ ,  $2\text{CdCl}_2 \cdot \text{HCl} \cdot 4\text{H}_2\text{O}$ , and  $\text{CdCl}_2 \cdot \text{HCl} \cdot 3\text{H}_2\text{O}$ .  
R. T.

**Systems lithium chloride-water-ethyl alcohol and lithium bromide-water-ethyl alcohol.** J. P. SIMMONS, H. FREIMUTH, and H. RUSSELL (J. Amer. Chem. Soc., 1936, 58, 1692—1695).—Equilibrium data at  $25^\circ$  are recorded. The solid phases recognised are  $\text{LiCl}$ ,  $\text{LiCl} \cdot \text{H}_2\text{O}$ ,  $\text{LiBr}$ ,  $\text{LiBr} \cdot \text{H}_2\text{O}$ , and  $\text{LiBr} \cdot 2\text{H}_2\text{O}$ . No alcoholates were detected.  
E. S. H.

**Reduction equilibrium of silver sulphide by hydrogen.** K. SANO (Sci. Rep. Tohoku, 1936, 25, 186—196).—The equilibrium const. for  $\text{Ag}_2\text{S} + \text{H}_2 = 2\text{Ag} + \text{H}_2\text{S}$  between  $490^\circ$  and  $660^\circ$  is expressed by  $\log K_p = 11.7/T - 0.741$ . The heat of reaction, change in free energy, and entropy change are  $\Delta H_{298} 2726$  g.-cal.,  $\Delta F_{298} 1896$  g.-cal.,  $\Delta S_{298} = 2.79$  e.u., respectively. For  $2\text{Ag} + \text{S}(\text{rhombic}) = \text{Ag}_2\text{S}(\text{rhombic})$ ,  $\Delta H_{298}$

$= -7486$  g.-cal.,  $\Delta F_{298} = -9736$  g.-cal., and  $\Delta S_{298} = 7.55$  e.u.  
O. D. S.

**Effect of structure on reactions of organic compounds. Temperature and solvent influences.** L. P. HAMMETT (J. Chem. Physics, 1936, 4, 613—617).—The heat and free energy of ionisation of an org. acid are not equally affected by a substituent. The entropy of ionisation of derivatives of  $\text{BzOH}$  varies in a manner which is predictable from the dielectric const.,  $\epsilon$ , of the solvent and is closely correlated with the effect of a change of  $\epsilon$  on the relative strengths of the substituted and unsubstituted acids. Aliphatic acids do not show similar relations and this is probably connected with their less rigid structure. Other equilibria and reaction rates are similarly considered.  
J. G. A. G.

**Thermodynamic properties of phosphorus compounds.** T. F. ANDERSON and D. M. YOST (J. Chem. Physics, 1936, 4, 529—530).—Raman spectrum, electron diffraction, and equilibrium data lead to the following standard virtual entropies (g.-cal. per  $1^\circ$ ):  $\text{P}$  (solid, white)  $10.55$ ,  $\text{P}_4$  (gas)  $66.88$ ,  $\text{PCl}_3$  (gas)  $74.7$ ,  $\text{PCl}_3$  (liquid)  $52.8$ ,  $\text{PCl}_5$  (gas)  $87.7$ , and  $\text{PCl}_5$  (solid)  $40.8$ ; the corresponding standard free energies of formation are  $0$ ,  $585$ ,  $-63,570$ ,  $-64,650$ ,  $-72,540$ , and  $-77,950$  g.-cal., respectively.  
J. G. A. G.

**Atomic heats of formation and bond energies.** F. G. SOPER (J.C.S., 1936, 1126—1130).—Linking energies calc. from the at. heats of formation of org. compounds are only approx. const., the increment in heat of formation between successive members of a homologous series (due to formation of one C-C and two C-H linkings) varying with the nature of the series. However, if the at. heats of formation are corr. for the intramol. potential energy arising from coulombic attractions and repulsions between the constituent atoms (calc. from the dipole moments of the linkings) the linking energies are more nearly const. for the paraffin, alcohol, and alkyl halide series.  
J. W. S.

**Heat capacity of aqueous solutions of barium chloride.** C. M. WHITE (J. Amer. Chem. Soc., 1936, 58, 1615—1620).—Modified apparatus and technique, increasing the precision to  $\pm 0.01\%$ , are described. Data are recorded for  $0.003$ — $0.3M$ - $\text{BaCl}_2$  at  $25^\circ$ . The apparent mol. heat capacity is related linearly to  $[\text{BaCl}_2]^{\frac{1}{2}}$ .  
E. S. H.

**Heat capacity and entropy of barium chloride dihydrate from  $15^\circ$  to  $300$  abs. Heat of dissolution of barium chloride dihydrate. Entropy of barium ion.** O. L. I. BROWN, W. V. SMITH, and W. M. LATIMER (J. Amer. Chem. Soc., 1936, 58, 1758—1759).—The entropy of  $\text{Ba}^{++}$ , calc. from the above determinations, is  $2.2$  e.u.  
E. S. H.

**Heat capacity of aqueous solutions of carbamide and mannitol.** C. M. WHITE (J. Amer. Chem. Soc., 1936, 58, 1620—1623).—Data for  $0.01$ — $1.0M$  solutions with a precision of  $\pm 0.01\%$  are recorded. The apparent mol. heat capacities are related linearly to  $\sqrt{M}$ .  
E. S. H.

**Heats of dissolution of salts in heavy water.** E. LANGE and W. MARTIN (Z. Elektrochem., 1936,

42, 662—668).—The heats of dissolution ( $L$ ) of alkali halides in  $D_2O$  and  $H_2O$  have been measured. The difference in  $L$  for the same salt in  $D_2O$  and  $H_2O$  ( $\Delta L$ ) varies with both anion and cation. The results are explained by assuming that  $L$  is not only produced by the electrostatic effects but is also modified by van der Waals forces and by an absorption of energy in creating space in the solvent for the solute mols.

J. W. S.

**Thermochemistry of titanium oxides. II. Thermochemical calculations.** N. NASU (J. Chem. Soc. Japan, 1935, 56, 659—666; cf. this vol., 682).—The following data are deduced:  $2TiO_2 + H_2 = Ti_2O_3 + H_2O$ ,  $\Delta H_{298} = 4700$  g.-cal.,  $\Delta F_{298} = 5280$  g.-cal.,  $\Delta S_{298} = 1.95$  g.-cal. per  $1^\circ$ ;  $Ti_2O_3 + \frac{1}{2}O_2 = 2TiO_2$ ,  $\Delta H_{298} = -62,530$  g.-cal.,  $\Delta F_{298} = -59,770$  g.-cal.,  $\Delta S_{298} = -9.26$  g.-cal. per  $1^\circ$ ;  $2Ti + 1.5O_2 = Ti_2O_3$ ,  $\Delta H_{298} = -388,070$  g.-cal.;  $2TiO_2 + CO = Ti_2O_3 + CO_2$ ,  $\Delta F_{298} = -6220$  g.-cal. The lattice energy of  $Ti_2O_3$  is 3569 kg.-cal.

CH. ABS. (e)

**Thermal data. VI. Heats of combustion and free energies of seven organic compounds containing nitrogen.** H. M. HUFFMAN, E. L. ELLIS, and S. W. FOX (J. Amer. Chem. Soc., 1936, 58, 1728—1733; cf. A., 1935, 304).—The heats of combustion at const. vol. of *d*-alanine, *l*-asparagine, *l*-asparagine monohydrate, *l*-aspartic acid, *d*-glutamic acid, creatinine, and creatine have been determined at  $25^\circ$ . The heats of formation and free energies are calc.

E. S. H.

**Heats of combustion and formation of dibutyl and diamyl phthalates.** H. R. AMBLER (J.S.C.I., 1936, 55, 291—292T).—The vals. recorded are, respectively,  $7396 \pm 10$  and  $7713 \pm 10$  g.-cal. per g. at const. pressure. These vals. agree with those derived from the structure of the compounds, but not with vals. in the literature (cf. Schmidt, B., 1934, 1085).

**Single linking energies. III. C-C linking in diphenyldidiphenylene-ethane.** H. E. BENT and J. E. CLINE (J. Amer. Chem. Soc., 1936, 59, 1624—1627; cf. this vol., 291).—The heat of oxidation of diphenyldidiphenylene-ethane is about 20 kg.-cal. < that of  $C_6Ph_6$ . Steric hindrance is < with  $C_6Ph_6$ , and the free radical formed by dissociation, phenylfluoryl, has more resonance energy than  $CPh_3$ .

E. S. H.

**Thermodynamic extension of the diffusion equation.** U. DEHLINGER (Z. Physik, 1936, 102, 633—640).—The Fick diffusion equation is shown to be the special case for ideal mixtures of the author's general diffusion equation (cf. A., 1933, 896). By means of the general equation the probability of change of position is calc. for Au-Ni mixtures from the results of Jédule (*ibid.*, 1006). The probability is greater in the mixed crystals than in either pure phase.

O. D. S.

**Conductance of salts (potassium acetate) and the dissociation constant of acetic acid in deuterium oxide.** V. K. LA MER and J. P. CHITTUM (J. Amer. Chem. Soc., 1936, 58, 1642—1644).—The Walden const. increases linearly by 1.93% in passing from  $H_2O$  to  $D_2O$  for KOAc and KCl. From the data

4 s

the dissociation consts. of weak acids in  $D_2O$  can be calc. with the aid of conductivity data. The dissociation const. of AcOH ( $0.55 \times 10^{-5}$  in pure  $D_2O$ ) shows a marked negative deviation from linearity on passing from  $H_2O$  to  $D_2O$ .

E. S. H.

**Hydrogen cyanide. VIII. Conductivity of electrolytes in anhydrous hydrogen cyanide. Some univalent salts at  $18^\circ$ .** J. E. COATES and E. G. TAYLOR (J.C.S., 1936, 1245—1256).—The  $\Lambda$  of 21 salts has been measured from 0.0001N to 0.002N, and the ionic mobilities have been calc. on the basis of Walden's rule. In most cases  $\Lambda_c - \Lambda_o - x\sqrt{C}$ , although for LiCl, LiNO<sub>3</sub>, and LiCNS the val. of  $x$  is > that calc. from the Debye-Hückel-Onsager equation on account of incomplete dissociation. The calc. dissociation consts. for these salts are respectively 0.11, 0.07, and 0.043.

C. R. H.

**Electrochemical investigation of the ternary system: aluminium bromide-silver and copper halides in ethyl bromide, ethylene dibromide, and benzene.** V. A. PLOTNIKOV and E. J. GORENBEIN (Acta Physicochim. U.R.S.S., 1936, 4, 775—790).—The electrical conductivity of the systems AgX-AlBr<sub>3</sub> and CuX-AlBr<sub>3</sub> (X=Cl, Br, I) in EtBr, C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>, and C<sub>6</sub>H<sub>6</sub> has been determined. The sp. conductivity increases with the concn. of halide at first rapidly, and then more slowly, attaining vals. of  $10^2$  in conc. solutions. The conductivity in C<sub>6</sub>H<sub>6</sub> is > that in C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub> for solutions of the same mol. concn., although the dielectric const. ( $\epsilon$ ) of C<sub>6</sub>H<sub>6</sub> is < that of C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>. Similarly the conductivity in EtBr is only twice as great as that in C<sub>6</sub>H<sub>6</sub> although  $\epsilon$  of EtBr is four times that of C<sub>6</sub>H<sub>6</sub>, and the dipole moment ( $\mu$ ) of EtBr is considerable. It is concluded that the chemical and electrochemical activity of a solvent is not completely characterised by  $\mu$ , and that  $\epsilon$  is not the principal const. on which the electrical conductivity of a solution depends. Electrolysis of the above solutions gave Ag and Cu<sup>+</sup> at the cathode, and Br at the anode, the best deposit being obtained when X=Cl. The decomp. potentials of the Cu<sup>+</sup> and Ag halides in the above solutions were determined.

A. J. M.

**Streamline scattering in electrolytes.** W. KANGRO and K. M. WAGNER (Z. Elektrochem., 1936, 42, 669).—The current distribution within and outside the space between the electrodes has been determined. Within the electrode zone the relations are complicated, but for the region outside this zone a streamline scattering const. can be calc. which varies little with the ionic strength or chemical nature of the ions, but is dependent on the conductivity and total c.d. With an angular cathode the distribution within the electrode zone deviates from ideal distribution in a manner analogous to that in the outer region.

J. W. S.

**Normal potential of the silver-silver bromide electrode from  $5^\circ$  to  $40^\circ$ .** B. B. OWEN and L. FOERING (J. Amer. Chem. Soc., 1936, 58, 1575—1577).—Data have been obtained by comparison with the Ag-AgCl electrode in Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> solutions. The Ag-AgBr (fused) electrode is highly reproducible.

E. S. H.

**Potential of mercury electrodes in solutions of salts of other metals.** T. ERDEY-GRÚZ and P. SZARVAS (Z. physikal. Chem., 1936, 177, 277—291; cf. A., 1935, 706).—The potential,  $E$ , of stationary and dropping Hg electrodes in  $O_2$ -free solutions containing salts of other metals and no Hg ions has been measured. For the stationary electrode  $E$  is determined by the concn. of the anions present, and is given approx. by  $E = E_0 + k \log a_{\pm}$ , where  $a_{\pm}$  is the mean ionic activity of the solution. With increase in the capillary activity of the anion  $E$  becomes more negative and more definite. It must therefore be supposed that  $E$  is due to the adsorption of the anion on the Hg; the above relation indicates that Freundlich's isotherm is valid for the adsorption. The adsorbed anion induces a positive charge on the Hg surface, which is therefore left negatively charged by detachment of drops. This negative charge lessens the adsorption of anions until ultimately at a quite small rate of dropping the surface charge,  $Q$ , becomes zero, and  $E$  assumes a const. val. which does not change with further increase in the rate of dropping. In the ordinary Paschen dropping electrode the  $E$  corresponding with zero  $Q$  is reached in the same way, and Hg ions play no part in establishing this val. of  $E$  (cf. A., 1933, 128). R. C.

**Electrode potentials of dilute amalgams.** T. ERDEY-GRÚZ and A. VAZSONYI-ZILAHY (Z. physikal. Chem., 1936, 177, 292—305).—The potentials,  $E$ , of stationary and dropping amalgam electrodes of concn.  $c$  in solutions free from Hg ions and  $O_2$  but containing ions of the metal in the amalgam,  $M$ , have been measured. At concn. up to a certain crit. concn.  $c_1$  ( $\sim 10^{-6}$  g.-ion per litre)  $E$  at a stationary electrode is independent of  $c$  and approx. the same as  $E$  for a pure Hg electrode in that particular electrolyte. As  $c$  rises above  $E$  begins to be influenced by the  $M$  ions, but varies with  $c$  much more rapidly than corresponds with Nernst's electrode potential formula. From a concn.  $c_2$  ( $10^{-6}$ — $10^{-4}$  g.-ions per litre) onwards the relation between  $E$  and  $c$  follows this formula. A dropping electrode behaves similarly to a stationary electrode, except that  $c_2$  is usually higher. It may be supposed that at concns. up to  $c_1$ ,  $E$  is determined solely by the adsorption of the foreign ions present in solution (cf. preceding abstract). Between  $c_1$  and  $c_2$   $E$  is determined by the distribution of  $M$  ions between the solution and the electrode and also by all the other ions present. R. C.

**Potential differences at metal-vapour, vapour-liquid, and liquid-metal interfaces of partially immersed electrodes.** C. G. FINK and R. C. DEHMEL (Trans. Electrochem. Soc., 1936, 70, Preprint 23, 245—284).—Apparatus is described for determining the p.d. across the vapour between the exposed portion of a partly immersed electrode and the surface of the solution into which it dips. Experiments with Cu, Au, and Pt electrodes in  $M$  solutions of their salts gave the following vals. for the p.d.: in presence of  $O_2$  at 1 atm. pressure, Cu +0.175 (temp. 22°), Au -0.33 (26.9°), Pt -0.19 volt (21.1°); in the absence of  $O_2$  the vals. at the same temp. are: Cu -0.151, Au -0.839, Pt -0.76 volt. When  $O_2$  is introduced the ratio of change in

solution potential to change in p.d. existing across the vapour phase in the case of Cu and Au is approx. 1:100, but is nearer unity for Pt.  $O_2$  causes the solution potential of each metal to become less anodic. In cells having Cu or Au electrodes equilibrium potential is rapidly established, but much less quickly in the case of bright Pt electrodes. Natural atm. ionisation is insufficient to render the p.d. across the vapour phase important as a factor in electrode corrosion. J. W. C.

**Polarographic studies with the dropping mercury cathode. LX. Influence of buffers and cations on the electro-reduction of fumaric and maleic acids.** E. VOPIČKA (Coll. Czech. Chem. Comm., 1936, 8, 349—365).—In HCl and in AcOH-NaOAc buffers the "half-wave potential" depends on the  $p_H$ , and remains const. over a wide range of concn. of maleic and fumaric acids. The former is reduced at more positive potentials than is the latter. In LiOH the "half-wave potential" becomes more positive with increase of  $p_H$  and in presence of  $Ca^{++}$  the fumarate ion is reduced at more positive potentials than is the maleate ion. C. R. H.

**$p_H$  values of some alkaline products.** A. T. WILLIAMSON and W. G. OAKES (J. Text. Inst., 1936, 27, T197—198).—The following  $p_H$  vals. are recorded for 0.2% solutions with H and Sb electrodes: NaOH, 12.69;  $Na_2SiO_3 \cdot 5H_2O$ , 11.94;  $Na_3PO_4 \cdot 12H_2O$ , 11.67;  $Na_2CO_3$ , 11.17;  $Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$ , 10.11;  $Na_2B_4O_7 \cdot 10H_2O$ , 9.15;  $NaHCO_3$ , 8.43. A. G.

**Electrochemical reduction potential of pyrrole-aldehyde.** G. B. BONINO and G. SCARAMIELLI (Ric. sci. Prog. tecn., 1935, 6, II, 111—112; Chem. Zentr., 1935, ii, 3897).—The reduction potential of pyrrole-aldehyde (I) is 1.254 volts and that of PhCHO 1.054 volts; in accordance with conclusions from Raman spectra, the results suggest that (I) is not enolic in structure. H. N. R.

**Influence of pressure on the electrode potential in the electrolysis of water. IV.** V. SCHUSCHKIN and E. KARNAUCH (Z. Elektrochem., 1936, 42, 693—695; cf. A., 1934, 1178).—Sudden increase of pressure from 1 to 100 kg. per sq. cm. slightly diminishes the cathode potential at a Ni electrode in 5N-NaOH, whilst release of the pressure increases it again, especially at low c.d. The effect is  $> 0.008$  volt. A similar but smaller effect is observed for the anode potential at Ni and for the cathode potential at Fe electrodes. It is inferred that the decrease in overpotential forms only a small part in the change of p.d. observed in the electrolysis of  $H_2O$  under pressure. J. W. S.

**Chemical polarisation of the hydrogen electrode by oxygen and the problem of electrolytic corrosion protection.** A. E. LORCH (Trans. Electrochem. Soc., 1936, 70, Preprint 15, 173—178).—The H electrode has been polarised by introducing  $O_2$  into the stream of  $H_2$ ; if  $i$  is the current required to polarise the electrode to the same extent as the  $O_2$  it is found that  $i = k[O_2]$ , when  $k$  is an approx. const. The current equiv. of the  $[O_2]$  is const. over a wide range of p.d. The bearing on protection from electrolytic corrosion is discussed. R. S. B.

**Overvoltage ; effect of fusion of the cathode and the effect of temperature on gas polarisation.** A. BUTTS and W. A. JOHNSON (Trans. Electrochem. Soc., 1936, 70, Preprint 19, 205—220).—From the variation of voltage with time and temp. at const. c.d. for cells containing Pt anodes and Wood's metal or Ga cathodes in 25%  $\text{H}_2\text{SO}_4$  it has been shown that no change in polarisation occurs on melting or freezing the cathode, so that H overvoltage is independent of internal physical structure or total energy content of the cathode. Changes in voltage occur with Wood's alloy which has not reached equilibrium, and sharp changes occur with liquid Ga. The H overvoltage is  $0.63 \pm 0.05$  volt at  $70\text{--}85^\circ$  on Wood's metal and  $0.60 \pm 0.05$  volt at  $25\text{--}30^\circ$  on Ga.

R. S. B.

**Mechanism of the electrolytic liberation of hydrogen at palladium and platinum.** L. KANDLER and C. A. KNORR (Z. Elektrochem., 1936, 42, 669).—The difference in form of the c.d.-cathode potential curve in the electrolysis of 2N- $\text{H}_2\text{SO}_4$  with Pt or Pd electrodes when (a) no gas, (b)  $\text{N}_2$ , and (c)  $\text{H}_2$  is passed through the cathode vessel during the measurement is attributed to the back reaction  $\text{H}_2 \rightarrow 2\text{H}$ , which occurs to a considerable extent in presence of excess of  $\text{H}_2$ , but is inappreciable when the  $\text{H}_2$  is swept away with  $\text{N}_2$ .

J. W. S.

**Difficulties encountered in the determination of the decomposition potential of molten salts.** P. DROSSBACH (Trans. Electrochem. Soc., 1936, 70, Preprint 18, 201—204).—The neglect of the influence of dispersed metal by many previous investigators leads to errors, owing to the development of a polarisation p.d. If anodic and cathodic regions are not separated current efficiency decreases rapidly with rise in temp. and thermodynamic formulæ cannot be applied to determine the heat of reaction. Polarisation processes are discussed.

R. S. B.

**Drop of potential in the metallic electrodes of certain electrolytic cells.** C. SNOW (J. Res. Nat. Bur. Stand., 1936, 17, 101—124).—Theoretical. Formulæ are derived for the drop of potential in thin metallic electrodes used for the measurement of the electrolytic resistance of solutions.

O. J. W.

**Simultaneous discharge of copper and hydrogen in solutions of complex cyanic salts.** O. ESSIN and A. MATANZEV (J. Chim. phys., 1936, 33, 631—639; cf. this vol., 32).—The discharge of Cu in solutions containing  $\text{CuCN} \cdot 1.5\text{KCN}$  is accompanied only by a concn. polarisation due to diminution in  $[\text{Cu}(\text{CN})_2^-]$  and accumulation of  $\text{CN}^-$  near the cathode. The current distribution between Cu and  $\text{H}^+$  discharged simultaneously is in agreement with a theoretical equation.

R. S.

**Co-deposition of metals of the same valency in acid solutions.** W. G. PARKS and I. M. LE BARON (Trans. Electrochem. Soc., 1936, 70, Preprint 21, 235—239).—For the metal pairs Zn—Cd, Cu—Cd, Ni—Cu, Zn—Cu, and Ag—Tl in solutions of  $p_{\text{H}}$  5, the limiting % concn. in solution at which the added metal is alone deposited varies linearly with log c.d. The respective effects of difference in electrode potential

and in equiv. wt. of the two metals on the limits of co-deposition are discussed.

J. W. C.

**Passivity of iron and steel in nitric acid solutions.** K. Y. YAMAMOTO (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 981—1054).—Potentiometric data at  $70^\circ$  indicate that activation of Fe occurs by reduction of  $\text{Fe}_2\text{O}_3$  to  $\text{FeO}$ . Passivation is hindered by  $\text{CO}(\text{NH}_2)_2$ , due to removal of  $\text{HNO}_2$ , and facilitated by  $\text{AgNO}_3$ , which forms  $\text{HNO}_2$  in presence of Fe.  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$  hinder passivation.

J. S. A.

**Energy of activation.** C. H. MACGILLAVRY (Chem. Weekblad, 1936, 33, 582—593).—A review.

S. C.

**Reaction rates of non-isothermal processes.** J. SHERMAN (Ind. Eng. Chem., 1936, 28, 1026—1031).—Mathematical. Reaction rates are derived for various time-temp. relations.

C. R. H.

**Explosion diagram.** E. M. BRUINS (Chem. Weekblad, 1936, 33, 566—570).—A mathematical analysis of various types.

S. C.

**Detonation of gaseous mixtures.** J. BRETON (Ann. Off. nat. Combust. liq., 1936, 11, 487—546).—Mixtures of known composition of  $\text{O}_2$  or air with  $\text{H}_2$ ,  $\text{CO}$ ,  $\text{NH}_3$ ,  $\text{C}_3\text{H}_8$ , isobutane,  $\text{C}_2\text{H}_2$ , or  $\text{Et}_2\text{O}$  were passed through a glass tube and detonated with Hg fulminate, photographs of the passage of the wave front being taken on a revolving cylinder. The detonation range in relation to the % of combustible gas in the mixture, and the max. rate of propagation, in m. per sec., with the corresponding mixture composition, are given for each of the above mixtures. The lower limit of detonation of  $\text{CO-O}_2$  mixtures was considerably lower when a small amount of  $\text{H}_2$  was added. An increase of the initial pressure extended the detonation range of  $\text{H}_2\text{-O}_2$  or  $\text{H}_2\text{-air}$  mixtures. Mixtures in the vicinity of the upper or lower limit produced helicoidal explosive waves. The photographic method enabled a study to be made of the non-luminous phenomena and of the mechanism of rupture of the glass tube as the explosive wave passed.

R. B. C.

**Propagation of explosion condensation through air.** L. THOMPSON (Physical Rev., 1935, [ii], 47, 811).—The velocity and intensity functions as affected by the quantity of explosive detonated and by the distance from the centre of the pulse at the instant of disintegration have been investigated.

L. S. T.

**Latent energy in explosions.** W. T. DAVID and A. S. LEAH (Phil. Mag., 1936, [vii], 22, 513—523).—The heat loss and pressure reached in explosions of  $\text{CO}$ ,  $\text{H}_2$ ,  $\text{C}_5\text{H}_{12}$  (vapour),  $\text{C}_2\text{H}_2$ , and  $\text{C}_2\text{H}_4$  with  $\text{O}_2$  or air, in different proportions, and at initial pressures of 0.25, 0.5, and 1 atm. have been determined. The amount of incomplete combustion increases as the initial pressure of the inflammable mixture decreases and is considerable at pressures  $< 1$  atm. This incomplete combustion is due to long-lived latent energy left in the exploded gases, which varies with the nature of the combustible gas, the nature of the diluent gas, and the pressure of the mixture before explosion.

A. J. M.

**Measurements of flame velocity by a modified burner method.** F. A. SMITH and S. F. PICKERING (J. Res. Nat. Bur. Stand., 1936, 17, 7—43).—The velocity of propagation of flame in mixtures of air with various combustible gases has been studied by means of the Bunsen-burner method. Data are given on the effect of varying the size of the air-inlet, of changing the velocity of flow of the mixture from the burner, of changing the composition of the mixture, and of different methods of measuring the flame and of calculating the results. Apparatus is described and the limitations of the method are discussed. O. J. W.

**Period of induction of cold flames in pentane-oxygen mixtures.** B. AIVAZOV and M. NEUMANN (Z. physikal. Chem., 1936, B, 33, 349—367).—The equation  $\tau = Ae^{v/T} [(a+b/d^2)/(1+[N_2]/p)]^2 (p-p_0)^2$  has been obtained empirically for the relation between the period of induction of the cold flame,  $\tau$ , temp.,  $T$ , vessel diameter,  $d$ , pressure,  $p$ , min. pressure at which a cold flame is formed,  $p_0$  ( $A$ ,  $\gamma$ ,  $a$ ,  $b$ —const.). MeCHO and NO<sub>2</sub> reduce both  $\tau$  and  $p_0$ . To explain the formation of cold flames it is suggested that the oxidation of hydrocarbons is a slowly developing chain reaction in which there is intercation of the chains, and that the reaction follows the equation  $dn/dt = -gn + fn$ , where  $n_0$  is the no. of active centres formed in 1 sec.,  $v$  the length of the primary chain,  $g$  the chain-breaking factor, and  $f$  the chain-branching factor, and  $f'n^2$  takes account of the chain interaction;  $f'$  is very small. At low pressures  $g > f$  and the reaction is stationary, whilst at higher pressures  $f > g$  and the reaction is autoaccelerated. This theory accounts for the above experimental relation. R. C.

**Reaction between ammonia and carbon dioxide.** T. YOSHIDA (Proc. Imp. Acad. Tokyo, 1936, 12, 191—194).—H<sub>2</sub>O vapour is necessary for the interaction of NH<sub>3</sub> and CO<sub>2</sub>. The data indicate that the reaction is of the second order and has a negative temp. coeff. C. R. H.

**Relative rates of combination of hydrogen and deuterium with ethylene.** A. WHEELER and R. N. PEASE (J. Amer. Chem. Soc., 1936, 58, 1665—1668).—In the homogeneous reaction near 500° the rate of reaction for H<sub>2</sub> is 2.5 times that for D<sub>2</sub>; in the catalytic reaction over Cu at 0° the rate for H<sub>2</sub> is twice that for D<sub>2</sub>. Exchange reactions are unimportant. E. S. H.

**Reactions of deuterium atoms with methane and ethane.** E. W. R. STEACIE and N. W. F. PHILLIPS (J. Chem. Physics, 1936, 4, 461—468).—The D atoms were produced by the discharge tube method and by photosensitisation with Hg. The activation energies of the reactions with CH<sub>4</sub> and C<sub>2</sub>H<sub>6</sub> are 11.7 and 6.3 kg.-cal., respectively (cf. A., 1935, 457). Experiments with CH<sub>3</sub>-C<sub>2</sub>H<sub>5</sub> mixtures show that the reaction C<sub>2</sub>H<sub>5</sub>+CH<sub>3</sub>=C<sub>2</sub>H<sub>4</sub>+CH<sub>4</sub> does not occur under the conditions. The mechanisms are discussed, and the measured activation energy, 6.3 kg.-cal., is that of the reaction D+C<sub>2</sub>H<sub>6</sub>=C<sub>2</sub>H<sub>5</sub>+HD; hence the process H+C<sub>2</sub>H<sub>6</sub>=Et+H<sub>2</sub> has approx. the same energy of activation. The bearing

of these results on the theory of free radical chains is discussed. J. G. A. G.

**Prototropy in relation to the exchange of hydrogen isotopes. I. Rates of isomerisation and of hydrogen isotope exchange in unsaturated nitriles.** C. K. INGOLD, E. DE SALAS, and C. L. WILSON (J.C.S., 1936, 1328—1334).—The rate of interconversion of  $\Delta^1$ -cyclohexenyl- (I) and cyclohexylidene- (II) -acetonitrile in 0.1N-NaOEt-EtOD has been compared with the rates of isotopic exchange between (I), (II), and the system (I) (II) and the medium at 25°. Rapid isotopic interchange (too great to be measured) of 2 H of (I) with D from the medium is followed by slow conversion of (I) into (II), which is in turn more rapid than H exchange between (II) and the medium, and is accompanied by a diminution in the D content of the total nitrile (I)+(II). Contrary to Kandiah *et al.* (A., 1929, 1294), the equilibrium proportion of (II) is indistinguishable from 100%. Analysis of the system (I)  $\xrightleftharpoons[k_2]{k_1}$  mesomeric ions  $\xrightleftharpoons[k_4]{k_3}$  (II) shows that  $k_1 \gg k_2$ ,  $k_3 \gg k_4$ , and  $(k_1/k_2)$

$(k_3/k_4)$ , the equilibrium val. of the ratio (D : H ratio in one exchanging position in the nitrile)/(D : H ratio in the exchanging position in EtOH) being 0.67. The lower D content of (II) than of (I) is explained by the fact that of the two positions concerned in exchange in each nitrile both of these in (I) and only one in (II) attain isotopic equilibrium with the medium, the second position in (II) being filled irreversibly, H<sup>+</sup> being taken up 4.1 times as fast as D<sup>+</sup>. H<sup>+</sup> is withdrawn from the nitrile 2.75 times as fast as D<sup>+</sup> by the OEt<sup>-</sup> ions of the medium. J. W. B.

**Homogeneous unimolecular decomposition of gaseous alkyl nitrites. VI. Decomposition of *n*-butyl nitrite.** E. W. R. STEACIE and W. McF. SMITH (J. Chem. Physics, 1936, 4, 504—507; cf. this vol., 33).—The rate of decomp. of 4—43 cm. of Bu<sup>o</sup>O·NO at 170—212° has been determined by the pressure changes. The reaction is unimol. and homogeneous, and the primary step is BuNO<sub>2</sub>=BuO+NO, but the reaction is not simple, as some tarry matter is also formed. The temp. coeff. leads to the energy of activation 36,000 kg.-cal. approx. Comparison shows that at 189.9°,  $k_{Me \cdot Et \cdot Pr \cdot Bu} = 0.97 : 1.89 : 3.95 : 3.70 : 8.88 \times 10^{-4}$  (cf. A., 1935, 938). J. G. A. G.

**Decomposition of azomethane. III. Effect of inert gases.** D. V. SICKMAN and O. K. RICE (J. Chem. Physics, 1936, 4, 608—613; cf. this vol., 684).—Kinetic data at 290° and 310° for Me<sub>2</sub>N<sub>2</sub>—"inert" gas mixtures afford relative activating efficiencies,  $\alpha$ , from which the following activating efficiencies per collision are calc.: Me<sub>2</sub>N<sub>2</sub> 1.00, N<sub>2</sub> 0.21, CO 0.13, CH<sub>4</sub> 0.20, H<sub>2</sub>O 0.46, CO<sub>2</sub> 0.25, D<sub>2</sub> 0.37, and He 0.07. The uniquely low val. for He suggests that exchange of vibrational energy between mols. is more probable than the transition of translational to vibrational energy. The val. of  $\alpha$  varies with pressure in mixtures of Me<sub>2</sub>N<sub>2</sub> with H<sub>2</sub>, C<sub>2</sub>H<sub>6</sub>, and C<sub>3</sub>H<sub>8</sub>, and Me<sub>2</sub>N<sub>2</sub> initiates a chain decomp. in *iso*-C<sub>4</sub>H<sub>10</sub>. J. G. A. G.

**Thermal decomposition of acetone.** J. R. HUFFMAN (J. Amer. Chem. Soc., 1936, 58, 1815—

1816).—The unimol. rate coeff. falls at low pressures in accordance with theory based on a free-radical chain mechanism. E. S. H.

**Kinetics of an inverse diene synthesis in the pure liquid state.** (A) B. S. KHAMBATA and A. WASSERMANN. (B) A. WASSERMANN (*Nature*, 1936, 138, 368, 369; cf. this vol., 684).—(A) Between 100° and 150° the decomp. of dicyclopentadiene in the pure liquid state follows the Arrhenius equation, and the rate const. is  $3 \times 10^{13} e^{-35400/RT}$  sec.<sup>-1</sup> in agreement with the const. in paraffin.

(B) Activation energies and temp.-independent factors are given. L. S. T.

**Velocity of hydrolysis of chlorine.** E. A. SHILOV and S. M. SOLODUSHENKOV (*Compt. rend. Acad. Sci. U.R.S.S.*, 1936, 3, 15—19; cf. A., 1935, 939).—Measurements were made at 1.2° and 18° by Hartridge and Roughton's flowing stream method (A., 1923, ii, 744) using Schmidt's mixing arrangement (A., 1929, 919); changes of concn. were followed conductometrically. The direct determination gave vals. of the velocity coeff.  $m$  in the equation  $-d[Cl_2]/dt = m[Cl_2] - n[HOCI][H^+][Cl^-] = 125$  at 1.2° and =700 at 18°, in good agreement with those given by the chlorination of PhOH (cf. A., 1926, 831).

R. C. M.

**Decomposition of fluosilicate ion in aqueous and in aqueous salt solutions.** A. G. REES and L. J. HUDLESTON (*J.C.S.*, 1936, 1334—1338).—The decomp. of  $SiF_6^{2-}$  in alkaline solution is unimol., the mechanism being:  $SiF_6^{2-} = SiF_4 + 2F^-$  (slow),  $SiF_4 + 3H_2O = 4HF + H_2SiO_3$  (rapid), followed by neutralisation of the acid.  $k$  is unaffected by alkali concn. or presence of added electrolyte. The degree of initial dissociation of the  $SiF_6^{2-}$  ( $R_0$ ) is deduced, and  $K = a_{SiF_4} a_{F^-} / a_{SiF_6^{2-}}$  calc. Added electrolyte decreases  $R_0$  owing to the increase of ionic strength of the solution, in quant. agreement with theory. A. J. E. W.

**Kinetic and equilibrium measurements of the reaction  $2Fe^{+++} + 2I^- = 2Fe^{++} + I_2$ .** A. V. HERSHEY and W. C. BRAY (*J. Amer. Chem. Soc.*, 1936, 58, 1760—1772).—Rate measurements at 25° and ionic strength 0.09 in aq. solutions containing  $H^+$ ,  $Fe^{+++}$ ,  $Fe^{++}$ ,  $I^-$ ,  $I$ ,  $K^+$ , and  $NO_3^-$  have been determined and evaluated. Intermediate compounds involved are discussed. Equilibrium data have been determined.

E. S. H.

**Kinetics of the reaction between ferric and stannous perchlorates in acid solution.** M. H. GORIN (*J. Amer. Chem. Soc.*, 1936, 58, 1787—1795).—Determinations of rate at 55° and 70° give no evidence of a direct reaction between  $Fe^{+++}$  and  $Sn^{++}$ . The rate-determining step for the reduction of  $Fe^{+++}$  is  $Fe(OH)_2^+ + Sn^{++}$ . When the hydrolysis equilibria are maintained the rate law is  $d(Fe^{++})/dt = 2k_3 k_1 k_2 (Fe^{+++})(Sn^{++}) / (H^+)^2$  when  $[Fe^{+++}]$  is high compared with  $[Sn^{++}]$ . The hydrolysis equilibria have been studied in the light of the above rate law. E. S. H.

**Influence of solvents on reaction velocity. Interaction of pyridine and methyl iodide and benzoylation of *m*-nitroaniline.** N. J. T. PICKLES and C. N. HINSHELWOOD (*J.C.S.*, 1936, 1353—1357).—The bimol. reactions between  $C_5H_5N$  and  $MeI$ ,

and between  $BzCl$  and  $m\text{-NO}_2\text{-C}_6\text{H}_4\text{-NH}_2$ , have been examined using various solvents, and vals. of  $k$  and the activation energy  $E$  obtained. The influence of the nature of the solvent on the consts.  $P$  and  $E$  in the equation  $k = PZ e^{-E/RT}$  ( $Z$  = collision no.) is discussed,  $Z$  being assumed const. For active solvents,  $E$  remains nearly const.,  $P$  varying in approx. parallelism with the dipole moment of the solvent. For inert solvents  $E$  increases. Variations in  $P$  are discussed. A. J. E. W.

**Kinetics of acid and alkaline hydrolysis of esters.** W. B. S. NEWLING and C. N. HINSHELWOOD (*J.C.S.*, 1936, 1357—1361).—Vals. of  $k$  and the activation energy  $E$  for the acid and alkaline hydrolysis of a no. of esters in aq.  $COMe_2$  solution have been obtained, and are discussed in relation to the equation  $k = PZ e^{-E/RT}$  (cf. preceding abstract). For a given ester,  $P$  is approx. const. for acid and alkaline hydrolysis, suggesting analogous mechanisms. Possible mechanisms are discussed. Results for  $P$  are not in accord with Soper's entropy change relation.

A. J. E. W.

**Reaction kinetics of acid hydrolysis of phenolic ethers.** R. P. GHASWALLA and F. G. DONNAN (*J.C.S.*, 1936, 1341—1346).—The acid hydrolysis of eight substituted anisoles and four substituted phenetoles by  $HCl$  and  $HBr$  has been investigated. The reactions are pseudo-unimol. with acid in excess, and formally of the third order with equiv. acid and ether,  $[HCl]^2$  occurring in the equation for  $k$ . This may be due to the formation of an intermediate oxonium compound the decomp. of which determines  $k$ , or to the acid functioning as undissociated mols. The effect of nuclear substituents on  $k$  is discussed.

A. J. E. W.

**Reaction of paraformaldehyde with cyanide.**—See this vol., 1362.

**Inflammation of dust clouds.**—See B., 1936, 964.

**Initial velocities of reduction of hæmatite and magnetite with hydrogen.** G. I. TSCHUFAROV and B. D. AVERBUCH (*Z. physikal. Chem.*, 1936, B, 33, 334—348; cf. this vol., 570).—The initial rate of reduction,  $v$ , in  $H_2$  at 0.001—0.1 mm. and at 300—800° has been determined. If a piece of magnetite is repeatedly heated in  $H_2$  so that reduction proceeds a stage further each time,  $v$  at a given  $H_2$  pressure increases with the no. of heatings, showing that reduction is autocatalysed. In the earlier stages of the reaction there is a period of induction which increases with fall in the temp. or  $H_2$  pressure. These observations are accounted for if it is supposed that reaction begins at active centres on the oxide surface, and when reaction occurs at a centre several new ones are formed. Above 600° the active surface is reduced by recrystallisation of the active centres, resulting in  $v$  being much smaller than at lower temp.

R. C.

**Autoxidation of unsaturated hydrocarbons.** I. P. PANJUTIN, L. HINDIN, and O. VASILJEEVA (*Compt. rend. Acad. Sci. U.R.S.S.*, 1936, 2, 183—186).—An EtOH solution of  $KI$  and conc.  $H_2SO_4$  was mixed with  $C_6H_6$  and kept in the dark for 4 hr. The amount of unchanged  $KI$  was determined by means of oxid-

ation with  $\text{Fe}^{\text{III}}$  salts. Liberated I was absorbed in KI and titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ . The peroxide no. in g. of I is calc. from a formula. W. R. A.

**Kinetics of rapid reactions. II. Starch iodide.** H. VON HALBAN and H. EISNER (Helv. Chim. Acta, 1936, 19, 915—927; cf. A., 1935, 1082).—Measurements by the streaming method of the rate of decolorisation of starch iodide by sulphite (I) or thiosulphate (II) indicate that at 25° the rate-determining process is the reaction between I and the reducing agent, the dissociation of the complex being immeasurably rapid. The observed rates decrease with increasing age of the complex and are, *ceteris paribus*, higher for (II) than for (I). The speed of reaction with (I) increases, and with (II) decreases, with increase of  $[\text{H}^+]$ . F. L. U.

**Kinetics of heterogeneous organic reactions. II. Reaction between benzyl chloride and solid silver nitrate in the presence of inert diluents.** M. V. NABAR and T. S. WHEELER (Proc. Indian Acad. Sci., 1936, 4, A, 91—96; cf. A., 1935, 1466).—The presence of dry  $\text{Et}_2\text{O}$ ,  $\text{CHCl}_3$ , and  $\text{CCl}_4$  inhibits the reaction, the effect of  $\text{Et}_2\text{O}$  being most marked. The rate of reaction  $\propto$  the surface of  $\text{AgNO}_3$  present, but is independent of the initial amount of a given mixture of  $\text{CH}_2\text{PhCl}$  and diluent. Results can be reproduced by a kinetic equation based on the assumption that the rate of reaction for a given initial mixture of  $\text{CH}_2\text{PhCl}$  and diluent depends only on the surface of the  $\text{AgNO}_3$ . The effect of the diluent may be due to adsorption on the  $\text{AgNO}_3$  surface. N. M. B.

**Autocatalysis in chemistry and biology.** A. MITTASCH (Chem.-Ztg., 1936, 60, 793—794).—A review.

**Influence of nitric oxide on the thermal decomposition of dimethyl ether. Gaseous catalysis.** P. F. GAY and M. W. TRAVERS (Nature, 1936, 138, 546—547; cf. this vol., 825, 1072).—Small amounts of NO reduce the rate of the thermal decomp.  $\text{Me}_2\text{O} = \text{CH}_3 + \text{CH}_3\text{O}$ , but larger amounts rapidly increase it. The reaction of NO with  $\text{Me}_2\text{O}$  gives rise to processes resulting in the formation of a short-lived intermediate which can decompose in two different ways. The oxidations can be represented by the equations  $\text{Me}_2\text{O} + \text{O} \rightarrow \text{OMe} \cdot \text{CH}_2 \cdot \text{OH}$  (I)  $\rightarrow (\text{CH}_3 + \text{CO}_2 + \text{H}_2)$  or  $(\text{CH}_3 + \text{CO} + \text{H}_2\text{O})$  and  $(\text{I}) + \text{O} \rightarrow \text{OMe} \cdot \text{CH}(\text{OH})_2 \rightarrow (\text{CH}_3 + \text{CO}_2 + \text{H}_2\text{O})$  or  $(\text{MeOH} + \text{CO} + \text{H}_2\text{O})$ . L. S. T.

**Ozone as an oxidising catalyst. XIII. Rate of transformation of systems obtained by ozonisation of aldehydes.** E. BRINER and A. LARDON (Helv. Chim. Acta, 1936, 19, 1062—1074; cf. this vol., 1075).—The system  $\text{PhCHO}$  (I)— $\text{BzO}_2\text{H}$  (II) is transformed into  $\text{BzOH}$  at approx. the same rate as is that obtained by ozonisation of (I), whence it is inferred that the peroxide formed in the latter reaction is (II). In support of this, the speed of the reaction between (I) and (II) is greater in  $\text{C}_6\text{H}_{14}$  than in  $\text{CCl}_4$ , corresponding with the higher proportion of (II) formed in the former solvent by ozonisation. The speed of reaction between  $\text{MeCHO}$  and  $\text{AcO}_2\text{H}$ , and the proportion of the latter formed by ozonisation, are greater in  $\text{CCl}_4$  than in  $\text{C}_6\text{H}_{14}$ . The course of the

transformation cannot be represented by any of the usual equations, and the process is considered to depend on chain reactions. F. L. U.

**Rates of some acid- and base-catalysed reactions, and dissociation constants of weak acids in "heavy" water.** J. C. HORNEL and J. A. V. BUTLER (J.C.S., 1936, 1361—1366).—The rates of hydrolysis in  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  of  $\text{MeOAc}$ , acetal (I), and  $\text{CH}(\text{OEt})_3$  (II) in acid solution, and of diacetone alcohol in alkaline solution have been determined by observing changes in  $n$  or  $\eta$ . Acid hydrolysis of (I) or (II) was used to determine the ratio of the dissociation consts. of some weak acids in  $\text{H}_2\text{O}$  and  $\text{D}_2\text{O}$  ( $K_D/K_H$ ). This ratio increases as  $K$  increases; this is interpreted by a modification of Halpern's theory (A., 1935, 1203),  $K_D/K_H$  being determined mainly by the force const. between the proton and the acid anion. A. J. E. W.

**Catalytic decomposition of diazoacetate ion in aqueous solution.** C. V. KING and E. C. BOLINGER (J. Amer. Chem. Soc., 1936, 58, 1533—1542).—The reaction of  $\text{CHN}_2 \cdot \text{CO}_2^-$  with  $\text{H}_2\text{O}$  is extremely sensitive to general acid catalysis. The mol. catalytic const. for  $\text{H}^+$ ,  $3.57 \times 10^8$  at 25°, is the highest recorded for any reaction. The mol. catalysis consts. decrease with increasing base or acid concn. There is a linear relation between the mol. consts. and the reciprocal of the base concn., except at low vals. of base concn. Mol. acid consts. at high base concn. agree with the Bronsted theory. Salt effects are described in relation to the mechanism. E. S. H.

**Catalytic action of lactoflavin-5'-phosphoric acid.**—See this vol., 1418.

**Application of transition state method to the heterogeneous reaction on hydrogen electrode; absolute calculation of isotopic interchange reaction velocity, cathodic and anodic currents, and isotopic separation factor.** G. OKAMOTO, J. HORIUTI, and K. HIROTA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 223—251).—The transition state method has been applied to the calculation of abs. reaction velocities for the H-Ni electrode, the rate-determining step being  $\text{H}_2 + 2\text{Ni} \rightarrow 2\text{H-Ni}$ . The authors' experimental results for anodic and cathodic currents, separation factor for H and D, velocity of interchange of H and D in  $\text{H}_2\text{O}$ , and temp. coeffs. of these processes, together with the relative adsorption velocities of  $\text{H}_2$  and  $\text{D}_2$  on Ni, and overvoltage, are successfully accounted for. The (110) plane of Ni is the most active, and activation of the catalyst probably consists in increasing the extent of the (110) plane, not the no. of active centres. R. S. B.

**Activation of specific linkings in complex molecules at catalytic surfaces. II. Carbon-hydrogen and carbon-carbon linkings in ethane and ethane-d.** K. MORIKAWA, W. S. BENEDICT, and H. S. TAYLOR (J. Amer. Chem. Soc., 1936, 58, 1795—1800; cf. this vol., 1213).—The exchange reaction between  $\text{C}_2\text{H}_6$  and  $\text{D}_2$  on a Ni catalyst occurs at lower temp. (100—130°) than that required for the reaction to yield  $\text{CH}_4$  (160—300°). The formation of  $\text{CH}_4$  has been studied kinetically; the surface reaction is

inhibited by  $H_2$ . At low  $[H_2]$  the side reactions  $2C_2H_6 = C + 3CH_4$  and  $C + 2H_2 = CH_4$  may predominate. The reaction of  $C_2H_6$  with  $H_2$  in presence of Ni, forming  $CH_4$ , has an activation energy approx. 43 kg.-cal.; the corresponding val. for the reaction with  $D_2$  is approx. 0.5 kg.-cal. higher. The activation energy of dissociative adsorption at the C-C linking is deduced to be  $>$  that of the C-H linking. The prep. of  $C_2D_6$  is described. E. S. H.

Water-gas reaction at a platinum surface at low pressure. G. M. SCHWAB and K. NAICKER (Z. Elektrochem., 1936, 42, 670—673).—The reaction between  $CO_2$  and  $H_2$  on a heated Pt wire has been studied at pressure of 0.01—0.1 mm. The temp. coeff. of the velocity of reaction ( $v$ ) of an equimol.  $H_2SO_4$ -dried mixture at 1300—1500° indicates a heat of activation of 35 kg.-cal. per mol. Excess of  $CO_2$  has little effect on the reaction, which is unimol., but shows an initial period of autocatalysis which disappears when CO is initially present in the reaction vessel. This effect is attributed to preformation of active centres. When the gases are  $P_2O_5$ -dried there is no autocatalysis and the reaction is of zero order, CO has a retarding effect, whilst excess of  $H_2$  is without effect. When the gases are dried to a  $H_2O$ -v.p. of  $2 \times 10^{-4}$  mm. by immersion in a bath at  $-90^\circ$ ,  $v$  has a very high temp. coeff. between 700° and 800°, and above about 900° remains const. at a high val. This indicates that with  $P_2O_5$ -dried gases there is a retardation of the reaction, attributed to poisoning of the active centres. J. W. S.

Structure of the electric double layer of platinised platinum and velocity of hydrogenation of benzene in a liquid medium. B. FORESTI (Gazzetta, 1936, 66, 464—475; cf. following abstract).—The rate of hydrogenation of  $C_6H_6$  suspended in solutions of KCl of varying  $p_H$  and in presence of platinised Pt has been measured. There is a max. velocity at about  $p_H$  0, which corresponds with the  $p_H$  at which the Pt electrode has zero charge.

O. J. W.

Relation between the activity of the hydrogen ions of the medium and velocity of hydrogenation of benzene and of oxygen in a liquid medium and in presence of platinum. B. FORESTI (Gaz-

zetta, 1936, 66, 455—459).—The rate of hydrogenation of O and of  $C_6H_6$  suspended in aq. solutions in presence of platinised Pt is greatly influenced by the  $p_H$  of the solution, especially when the Pt catalyst is very active.

O. J. W.

Temperature coefficient of the electrolytic separation of the hydrogen isotopes. H. F. WALTON and J. H. WOLFENDEN (Nature, 1936, 138, 468).—The temp. variation of the electrolytic separation of the H isotopes at Hg and Ag cathodes has been measured at c.d.  $>$  1 milliamp. per sq. cm. At Ag, the separation coeff. falls with a rise in temp., whilst that at Hg is practically unchanged. Addition of  $\alpha$ -naphthaquinoline, which might be expected to inhibit any catalytic mechanism, lowers the coeff. markedly in both cases, and changes the sign of the temp. coeff.

Europium. H. N. MCCOY (J. Amer. Chem. Soc., 1936, 58, 1577—1580).—The electrolytic reduction of  $Eu^{+++}$  to  $Eu^{++}$  is described. The reduction potential of the  $Eu^{+++}$ ,  $Eu^{++}$  electrode is 0.4313 volt. In solutions of  $Eu^{++}$  complete absorption of visible light occurs below 4480 Å.; the bands of the absorption spectrum of  $Eu^{+++}$  solutions are not shown. The stability of  $Eu^{++}$  solutions to oxidation has been investigated. Cryst.  $EuSO_4$  is stable in air. Iodometric methods for the determination of Eu are described.

E. S. H.

Electrochemical investigations with  $\alpha$ -hydroxy-acids. E. TOMMILA (Ann. Acad. Sci. Fennicae, 1936, A, 46, 1—95; cf. A., 1935, 960).—The electrolytic oxidation of a no. of aliphatic and aromatic  $\alpha$ -OH-acids in 2—5*N*-NaOH solution and with bright and platinised Pt, Ni, and Fe anodes has been investigated. With Ni and Fe anodes the reaction proceeds almost independently of anode potential, yielding almost exclusively the corresponding  $\alpha$ -keto-acids, whilst at Pt anodes it yields mainly  $CO_2$  and the next lower aldehyde. Under special conditions  $H_2$  and hydrocarbons can be formed at a bright Pt anode, this phenomenon being least common with the lower members of the series. For each  $\alpha$ -OH-acid there are two separate regions of oxidation potential,

corresponding with decomp. with and without  $O_2$  evolution, respectively. In some cases periodic oscillation between the two potentials is observed.

J. W. S.

**Polarographic studies with the dropping mercury cathode. LXI. Effect of buffer solutions on the reaction of proteins.** R. BRDIČKA (Coll. Czech. Chem. Comm., 1936, 8, 366—376).—The catalytic effect of ovalbumin, peptone, and cysteine in lowering the over-potential of the deposition of H ions has been investigated in buffer solutions. The presence of cystine nuclei in the protein is considered essential for the catalytic action.

C. R. H.

**Chemical action of electric discharges. XI. Production of nitric oxide by the electric arc at high frequency in mixtures of nitrogen and oxygen at reduced pressure.** E. BRINER, B. SIEGRIST, and H. PAILLARD (Helv. Chim. Acta, 1936, 19, 1074—1079; cf. this vol., 571).—Yields of  $HNO_3$  >500 g. per kw.-hr. have been obtained from equimol. mixtures of  $N_2$  and  $O_2$  by combining the use of a high-frequency arc ( $10^7$  cycles) with reduction of the gas pressure to about 70 mm. Such yields are due to the much smaller min. energy required to maintain a stable discharge. Under the conditions stated excess of  $O_2$  in the mixture and addition of Li to the electrodes have a less favourable influence.

F. L. U.

**Kinetics of recombination of iodine atoms.** E. RABINOWITCH and W. C. WOOD (J. Chem. Physics, 1936, 4, 497—504; cf. this vol., 398, 437).—The equilibrium  $I_2 + h\nu \rightarrow I + I$ ,  $I + I \rightarrow I_2$  in the presence of added gases is heterogeneous at low pressures. The atoms recombine mainly by diffusion to the walls, and the dissociation increases with rising pressure. At higher pressures, sp. for the added gas (e.g., 250 mm. in He, 40 mm. in  $CO_2$ ) there is a fairly sharp transition and the recombination becomes homogeneous. The walls have practically no effect at pressures > the transition val., and the dissociation  $\propto$  (light intensity) $^{\frac{1}{2}}$  and (pressure) $^{-\frac{1}{2}}$ , in accordance with the theory for recombination by three-body collisions. The velocity coeffs. of the reaction  $I + I + X \rightarrow I_2 + X$  for the different added gases, X, are calc., and the order of efficiency in promoting recombination is  $He < A < H_2 < N_2 < O_2 < CH_4 < CO_2 < C_6H_6$ . At atm. pressure, one binary collision of I atoms in 530 leads to recombination in He, but one in 50 is fruitful in  $CO_2$  (cf. this vol., 801).

J. G. A. G.

**Photochemical reduction of nitrates.** R. CULTRERA (Gazzetta, 1936, 66, 440—446).—When aq. solutions of  $HNO_3$  or of metallic nitrates are exposed to sunlight, or to the light of a C arc or of a quartz Hg lamp, some reduction to  $NO_2'$  takes place. With the Hg lamp radiation reduction to  $NH_3$  may also occur. In both reactions  $O_2$  is evolved. The effect of various factors on the amount of reduction products formed has been studied.

O. J. W.

**Theory of desensitisation.** LUPPO-CRAMER (Z. wiss. Phot., 1936, 35, 197—200).—AgBr-collodion emulsions (not dye-sensitised) are scarcely desensitised by the usual dyes. This fact was used by Weber (this vol., 808) for his theory of desensitisation as a

process of oxidation of chemical or optical sensitising substances. Previous work by the author has, however, shown that the latent image of collodion emulsions is resistant to bleaching and other reactions. The facts are therefore more in accord with the older theory that desensitisation is a process of oxidation of at. Ag to Ag ions.

J. L.

**Influence of grain size, separation, and distribution on the capability of enlargement of photomicrographs of biological objects.** F. BUCHTHAL and G. G. KNAPPEIS (Z. wiss. Phot., 1936, 35, 177—192).—The characteristics of the grains of nine emulsions have been determined by photomicrographs of single-grain layers within the emulsion and by microphotometric records of density. No definite relation between any characteristic and the capability of enlargement could be found. The methods of measurement and the results obtained are fully discussed.

J. L.

**Colloid substrate in photosynthesis.** M. COPPSAROW (Nature, 1936, 138, 509).

L. S. T.

**Photochemical decomposition of methane.** P. A. LEIGHTON and A. B. STEINER (J. Amer. Chem. Soc., 1936, 58, 1823).— $H_2$  and unsaturated hydrocarbons (probably  $C_2H_4$ ) are produced when  $CH_4$  is irradiated with the light transmitted by a thin fluorite window from a H $_2$  discharge tube.

E. S. H.

**Photochemical oxidation of methane, methyl chloride, and methylene chloride sensitised by chlorine.** W. BRENSCHKE and H. J. SCHUMACHER (Z. physikal. Chem., 1936, 177, 245—262).—When a mixture of  $Cl_2$  and  $O_2$  with  $CH_4$ ,  $MeCl$ , or  $CH_2Cl_2$  is irradiated with light of  $\lambda$  436 m $\mu$  the principal products are HCl and CO; small amounts of  $COCl_2$ ,  $H_2O$ , and less volatile org. compounds are also formed. The reaction has a chain mechanism and a quantum yield referred to CO formation rising from about 80 to 800 in the order  $CH_4 < MeCl < CH_2Cl_2$ . From  $CH_4$  and  $MeCl$  reaction proceeds by way of  $MeCl$  and  $CH_2Cl_2$ , and  $CH_2Cl_2$ , respectively. Up to the formation of  $CH_2Cl_2$  there is little oxidation of the hydrocarbon radicals participating in the chains.  $CH_2Cl_2$ , however, forms by collision with a Cl atom the  $CHCl_2$  radical, which reacts with  $O_2$  to give CO and HCl, some peroxide of short life being an intermediate product; after a period of induction the velocity of this reaction becomes const.

R. C.

**Action of ultra-violet light on halogenated hydrocarbons.**—See this vol., 1358.

**Behaviour of iodine in sensitised decompositions of gaseous organic compounds.** R. F. FAULL and G. K. ROLLEFSON (J. Amer. Chem. Soc., 1936, 58, 1755—1758).—Spectroscopic evidence shows that the [I] during sensitised decomp. of gaseous  $Et_2O$ ,  $MeCHO$ ,  $PrCHO$ ,  $(CH_3)_2O$ ,  $MeOH$ ,  $HCO_2Me$ , or  $CH_2O$  is very low. Definite chemical reactions are involved in the decomp.

E. S. H.

**Photochemical formation of peroxides. VI. Oxidation of formic acid in ultra-violet light by molecular oxygen.** Photochemical formation of performic acid. R. CANTIENT (Helv. Chim. Acta, 1936, 19, 1153—1158; cf. this vol., 1091).—Peroxide

is formed in both anhyd. and aq.  $\text{HCO}_2\text{H}$  in presence of  $\text{O}_2$  on exposure to ultra-violet light of short  $\lambda$ . The peroxide (I), which is not  $\text{H}_2\text{O}_2$ , is assumed to be performic acid. In presence of  $\text{HCO}_2\text{H}$  (I) decomposes at a rate which increases with its concn., so that a steady concn. is attained, which in the aq. acid is never  $>0.75\%$  in consequence of the strong ultra-violet absorption. F. L. U.

**Mechanism of decomposition. I. Vapour-phase photolysis of acetic acid. II. Photolysis of formic acid.** M. BURTON (J. Amer. Chem. Soc., 1936, 58, 1645—1654, 1655—1657).—I. During photolysis, H atoms, but no free Me radicals, are formed. The production of at. H is favoured slightly by decrease in  $\lambda$ ; none is produced at  $\lambda > 2300 \text{ \AA}$ . Energies of activation for two reactions involving AcOH and H atoms have been calc. A free-radical mechanism is put forward. The detection of H atoms in presence of free Me is described.

II. No H is produced during photolysis of  $\text{HCO}_2\text{H}$ ; a mechanism for the production of OH is formulated. A reaction with a fairly low energy of activation occurs between H and  $\text{HCO}_2\text{H}$ . Experiments with MeCHO show CHO to be a stable radical at room temp. E. S. H.

**Photo-rearrangement of o-nitrobenzaldehyde to o-nitrobenzoic acid.** L. KUHLER and F. PATAT (Monatsh., 1936, 68, 275—289).—The quantum yield in the photo-conversion of  $\text{o-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  into  $\text{o-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  in the vapour phase is  $>$  for this reaction in solution (cf. A., 1931, 1251; 1935, 48), but is  $<1$ . The mechanism of the reaction is discussed. J. W. S.

**Photochemical deamination of amino-acids in water solution.** C. WEIZMANN, E. BERGMANN, and Y. HIRSHBERG (J. Amer. Chem. Soc., 1936, 58, 1675—1678).—Glycine, alanine, betaine, and aspartic acid are hydrolysed in aq. solution under the influence of ultra-violet light, yielding corresponding OH-acids. The kinetics and quantum yields of the reactions have been determined and a mechanism is suggested. E. S. H.

**Photochemical studies. XXIV. Photochemical chlorination of dichlorobenzenes.** C. F. FISK and W. A. NOYES, jun. (J. Amer. Chem. Soc., 1936, 58, 1707—1714).—The rates of photochemical chlorination of o-, m-, and p- $\text{C}_6\text{H}_4\text{Cl}_2$  are equal. The rate  $\propto$  the light intensity at low intensities, but  $\propto$  some power of the intensity between 0.5 and 1.0 at higher intensities. The rate is independent of  $[\text{Cl}_2]$ , but  $\propto$   $[\text{C}_6\text{H}_4\text{Cl}_2]$ . The mechanism is discussed. E. S. H.

**Chemical reactions produced by ionisation processes. I. Ortho-para hydrogen conversion by  $\alpha$ -particles.** H. EYRING, J. O. HIRSCHFELDER, and H. S. TAYLOR (J. Chem. Physics, 1936, 4, 479—491).—Theoretical. The processes occurring in a gas ionised by  $\alpha$ -particles are considered. In  $\text{H}_2$ , approx. one ion in 5—9 is associated with a mol. Stable states of  $\text{H}_2^-$  exist, but the probability of formation is very small. Most neutralisation processes involve  $\text{H}_3^+$ , and 2—3 H atoms are produced, corresponding with 3—4 H atoms per ion pair formed. At. H is responsible for the large ratio of para- $\text{H}_2$

converted with respect to ions produced by  $\alpha$ -particles (cf. this vol., 171). H atoms are removed only slowly by the process  $\text{H} + \text{H} + \text{H}_2 \rightarrow 2\text{H}_2$  compared with the speed of recombination at the wall of the vessel, and Hg atoms are not effective. The results accord with the data (*loc. cit.*). J. G. A. G.

**Radiochemical synthesis and decomposition of hydrogen bromide.** H. EYRING, J. O. HIRSCHFELDER, and H. S. TAYLOR (J. Chem. Physics, 1936, 4, 570—575).—Theoretical. A mechanism is developed whereby the variations of yield per ion pair with change of  $[\text{H}_2]$ ,  $[\text{Br}_2]$ , and  $[\text{HBr}]$  are accounted for quantitatively (cf. this vol., 688). In pure  $\text{H}_2$  six H atoms are formed per ion pair, whilst in pure HBr six mols. are decomposed. In equal mixtures of  $\text{Br}_2$  and HBr, an electron forms a negative ion from HBr more frequently than from  $\text{Br}_2$ . J. G. A. G.

**Separation of isotopes.** G. CHAMPETIER (Bull. Soc. chim., 1936, [v], 3, 1701—1727).—A lecture.

**Exchange between sodium iodide and ethyl iodide.** D. E. HULL, C. H. SCHIFFLETT, and S. C. LIND (J. Amer. Chem. Soc., 1936, 58, 1822—1823).—Exchange between radioactive NaI and EtI in EtOH at  $100^\circ$  is demonstrated. E. S. H.

**Preparation of magnesium hypochlorite.**—See B., 1936, 986.

**Graduated [thermal] decomposition of barium dihydrogen oxalate dihydrate measured by the emanation method.** B. SAGORTSCHEV (Z. physikal. Chem., 1936, 177, 235—240).—There are formed successively  $\text{BaH}_2\text{C}_2\text{O}_4\cdot\text{H}_2\text{O}$ ,  $\text{BaH}_2\text{C}_2\text{O}_4$ ,  $4\text{BaC}_2\text{O}_4\cdot\text{H}_2\text{C}_2\text{O}_4$  (decomp. above  $210^\circ$ ),  $\text{BaC}_2\text{O}_4$ , and  $\text{BaCO}_3$ . R. C.

**Mercuric halides, cyanide, and thiocyanate.** K. BRAND and I. TURCK (Pharm. Zentr., 1936, 77, 591—593).— $\text{HgCl}_2$ ,  $\text{HgBr}_2$ ,  $\text{HgI}_2$ , and  $\text{Hg}(\text{CN})_2$  crystallise with 2,  $\text{Hg}(\text{SCN})_2$  with 1 mol. of dioxan of crystallisation which is readily lost in air. Dioxan is a good solvent for recrystallisation of  $\text{HgI}_2$ . R. S. C.

**Base-exchanging properties of synthetic aluminosilicate materials.**—See B., 1936, 986.

**Recent developments in the chemistry of the rare-earth group.** B. S. HOPKINS (J. Chem. Educ., 1936, 13, 363—368).—An address. L. S. T.

**Separation of yttrium from the yttrium earths.** H. C. FOGG and L. HESS (J. Amer. Chem. Soc., 1936, 58, 1751—1753).—Y is separated by fractional pptn. with  $\text{CO}(\text{NH}_2)_2$  at  $90$ — $95^\circ$ . E. S. H.

**Extraction of indium from cylindrite, chalcopyrite, and metallic tin.** F. M. BREWER and E. BAKER (J.C.S., 1936, 1290—1294).—Sn in metallic Sn is pptd. as  $\text{SnS}_2$ , and In subsequently co-pptd. with  $\text{Al}(\text{OH})_3$ ; alternatively, treatment with  $\text{Cl}_2$  volatilises Sn as  $\text{SnCl}_4$ , leaving In in the residue. Cu and Fe in chalcopyrite are pptd. with nitroso- $\beta$ -naphthol (I); some In is carried down, and separation is poor with low In content, making this source inconvenient. Pb, Sn, and Sb in cylindrite (an analysis of which is given) are pptd. as sulphides. In is then pptd. (with Fe and Zn) as hydroxide; Fe is separated with (I), and  $\text{Zn}(\text{OH})_2$  dissolved out with aq.  $\text{NH}_3$ .

Treatment with  $\text{NaHSO}_3$  gives In basic sulphite. Elimination of traces of Fe is troublesome.

A. J. E. W.

**Concentration of the carbon isotope.** H. C. UREY, A. H. W. ATEN, jun., and A. S. KESTON (J. Chem. Physics, 1936, 4, 622—623).—The % of  $^{13}\text{C}$  was increased from 1.06 to 1.36 by using  $\text{CO}_2$  and aq.  $\text{KHCO}_3$  containing carbonic anhydrase in a counter-current fractionating column apparatus.

J. G. A. G.

**Corrosion of silica by chlorine.**—See B., 1936, 989.

**Properties of the oxides of nitrogen. V. Combustion in the system nitric anhydride-ozone.** J. T. LEMON and T. M. LOWRY (J.C.S., 1936, 1409—1412).—Mixtures of  $\text{N}_2\text{O}_5$  and ozonised  $\text{O}_2$  (7—8%  $\text{O}_3$ ) contain a blue gas, probably  $\text{NO}_3$ . The mixture ignites at  $<100^\circ$ , burning with a characteristic blue flame and producing  $\text{N}_2\text{O}_4$ . The  $\text{NO}_3$  appears to burn in  $\text{O}_3$  with liberation of  $\text{O}_2$ :  $\text{NO}_3 + \text{O}_3 = \text{NO}_2 + 2\text{O}_2$  or  $2\text{NO}_3 = 2\text{NO}_2 + \text{O}_2$ . Once the combustion is initiated, a reaction such as  $\text{N}_2\text{O}_5 + \text{O}_3 = 2\text{NO}_2 + 2\text{O}_2$  may occur.

A. J. E. W.

**Nitrosyl of A. Angeli.** L. CAMBI (Ber., 1936, 69, [B], 2027—2033; cf. Oddo *et al.*, this vol., 460).—Anhyd.  $\text{MeCHO}$ ,  $\text{EtCHO}$ ,  $\text{Pr}^\text{c}\text{CHO}$ , and  $\text{BuCHO}$  do not react with  $\text{Na}_2\text{N}_2\text{O}_3$ ; Angeli's reaction with formation of  $\text{NaNO}$ , and  $\text{OH}\cdot\text{CR}\cdot\text{N}\cdot\text{ONa}$  is immediately induced by a little  $\text{H}_2\text{O}$ . In anhyd. media  $\text{PhSO}(\text{OH})\cdot\text{N}\cdot\text{ONa}$  (I) reacts immediately with  $\text{MeCHO}$  and  $\text{EtCHO}$ :  $(\text{I}) \rightarrow \text{R}\cdot\text{SO}_2\text{Na} + \text{NaNO}$  and  $\text{NaNO} + \text{R}\cdot\text{CHO} \rightarrow \text{OH}\cdot\text{CR}\cdot\text{N}\cdot\text{ONa}$ . After removal of the excess of aldehyde, the salt-like residue does not give the reactions characteristic of Piloty's acid (II). With  $\text{MeCHO}$  and  $\text{EtCHO}$  (II) yields compounds thus:  $\text{R}\cdot\text{CHO} + 2\text{SO}_2\text{Ph}\cdot\text{NH}\cdot\text{OH}$  (III)— $\text{H}_2\text{O}$  whereas with  $\text{Pr}^\text{c}\text{CHO}$  a mixture of  $\text{Pr}^\text{c}\text{CHO} + 2(\text{III})$ — $\text{H}_2\text{O}$  and  $\text{Pr}^\text{c}\text{CHO} + (\text{III})$ — $\text{H}_2\text{O}$  results. These are decomposed in complex manner by alkali, giving  $\text{N}_2$ ,  $\text{N}_2\text{O}$ , and traces of  $\text{NO}$  and yielding products containing N and S (including  $\text{PhSO}_2\text{H}$ ), but no hydroxamic acids. Their formation therefore does not involve Angeli's reaction. (II) and  $\text{CCl}_3\cdot\text{CH}(\text{OH})_2$  do not interact appreciably during several days. (II) appears unchanged by  $\text{PhCHO}$  in anhyd.  $\text{Et}_2\text{O}$ .  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$  and (II) slowly yield a brown resin and a colourless, cryst. material which does not give hydroxamic acids with alkali. Contrary to Oddo, therefore, it is concluded that Angeli's hypothesis of nitrosyl as an unsaturated radical logically connects the reactions of widely differing substances which only share the ability to afford  $\text{HNO}$  when decomposed. Nitrosyl therefore belongs to the group of free radicals and is comparable with  $\text{NH}\cdot\text{NPh}$  and  $\cdot\text{NPh}$ . In gaseous and liquid systems the formation of  $\text{HNO}$  as intermediate has frequently been observed.

H. W.

**Preparation of chemically pure phosphoric acid.**—See B., 1936, 930.

**Metaphosphoric acids.** R. SALIH (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, 77—84).— $\text{H}_6(\text{PO}_3)_6$  has been prepared by the action of  $\text{H}_2\text{S}$  on  $\text{Pb}_3(\text{PO}_3)_6$ . It is inferred from titration curves that four of the acidities are strong and two are weak.

R. S.

**Pyridinium vanadate.** S. KATZOFF and R. ROSEMAN (J. Amer. Chem. Soc., 1936, 58, 1785—1786).—The prep. and properties of  $(\text{C}_5\text{H}_6\text{N})_3\text{V}_5\text{O}_{14}\cdot\text{H}_2\text{O}$  are described.

E. S. H.

**Concentration of the oxygen isotopes.** H. C. UREY, G. B. PEGRAM, and J. R. HUFFMAN (J. Chem. Physics, 1936, 4, 623).—By means of a 35-ft. fractionating column with alternate cones rotating, the ratio of the O isotopes in  $\text{H}_2\text{O}$  was changed by a factor of three.

J. G. A. G.

**Preparation of amidosulphonic acid and imido-sulphonates.**—See this vol., 1237.

**Reactions in which metal atoms are exchanged between a gaseous and a solid phase.** G. BECKER, E. HERTEL, and C. KASTER (Z. physikal. Chem., 1936, 177, 213—223).—If  $\text{H}_2$  charged with  $\text{HCl}$  is passed over Cr and then over Fe at  $950^\circ$  the  $\text{CrCl}_2$  first formed reacts with the Fe:  $\text{Fe} + \text{CrCl}_2 = \text{FeCl}_2 + \text{Cr}$ . The Cr atoms formed on the surface of the Fe diffuse inwards, and new crystallites with a body-centred cubic lattice and consisting of a solid solution of Cr in Fe, apparently free from C, grow inwards from the surface; the depth of penetration may reach 1 mm. In the spaces between the Cr-Fe crystallites and between these and the Fe crystallites C accumulates, forming a eutectic alloy containing Cr 5, C 5, Fe 90%. Cr may be introduced into Ni and Co by a process similar to the above.

R. C.

**Effect of molecular nitrogen on molybdenum at high temperatures.** P. TURV and S. KRAUSZ (Nature, 1936, 138, 331).—Heating Mo wires electrically in  $\text{N}_2$  at  $1300^\circ$  raises the yield point and increases the extension of the wire under load. Cold-worked wires react more slowly with  $\text{N}_2$  than annealed. Deformation of nitrided wires restores the properties possessed prior to nitriding, but deformed nitrided wires revert to the nitrided stage after flashing even in A for 1—2 sec. Electrical resistivity is unaltered by nitriding. Heating in  $\text{H}_2$  or in a vac. denitrates the wires. Contamination of the wire surface by C and the presence of traces of  $\text{O}_2$  and/or  $\text{H}_2\text{O}$  vapour in the gas retard penetration of  $\text{N}_2$  into the wire.

L. S. T.

**Preparation and determination of elementary fluorine.** W. T. MILLER, jun., and L. A. BIGELOW (J. Amer. Chem. Soc., 1936, 58, 1585—1589).—Apparatus and procedure for the prep. of  $\text{F}_2$  and determination by absorption in Hg are described.

E. S. H.

**Complex nickel compounds. I. Formation and solvation of nickelous chloride in some non-aqueous liquids.** D. R. CHESTERMAN and A. S. NICKELSON (J.C.S., 1936, 1300—1302).—The reaction between Ni and  $\text{HCl}$  dissolved in various org. solvents has been studied. The reaction is more vigorous when the solvent is  $\text{MeOH}$ ,  $\text{EtOH}$ ,  $\text{Pr}^\text{c}\text{OH}$ ,  $\text{Pr}^\text{t}\text{OH}$ , or  $\text{AcOH}$  than when it is  $\text{Et}_2\text{O}$ ,  $\text{MeOAc}$ , or  $\text{EtOAc}$ . No reaction takes place in  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{CS}_2$ ,  $\text{C}_6\text{H}_6$ ,  $\text{PhNO}_2$ , or light petroleum. The following compounds were isolated:  $\text{NiCl}_2\cdot\text{MeOH}$ ;  $\text{NiCl}_2\cdot 2\text{MeOH}$ ;

$\text{NiCl}_2\cdot\text{EtOH}$ ;  $2\text{NiCl}_2\cdot\text{Pr}^\text{c}\text{OH}$ ;  $2\text{NiCl}_2\cdot\text{Pr}^\text{t}\text{OH}$ ;

$2\text{NiCl}_2\cdot\text{AcOH}$ ;  $\text{NiCl}_2\cdot\text{AcOH}$ ;  $\text{NiCl}_2\cdot\text{Et}_2\text{O}$ ;

$2\text{NiCl}_2\cdot\text{MeOAc}$ .

C. R. H.

**Affinity. LXX. Combination of palladium and phosphorus.** G. WIEHAGE, F. WEIBKE, and W. BILTZ [with K. MEISEL and F. WIECHMANN] (*Z. anorg. Chem.*, 1936, 228, 357—371).—Heating of Pd sponge in P vapour at 600—700° yields  $\text{PdP}_2$ . Thermal analysis of the system Pd— $\text{PdP}_2$  indicates the existence of a very stable *tripalladium phosphide*,  $\text{Pd}_3\text{P}$ , the compound  $\text{Pd}_5\text{P}_2$ , and a  $\beta$ -mixed crystal phase of mean composition  $\text{Pd}_5\text{P}$ . M.p., v.p., and X-ray measurements indicate no compounds between  $\text{Pd}_5\text{P}_2$  and  $\text{PdP}_2$ . The physical properties of Pd—P alloys of various compositions are described.

J. W. S.

**Co-ordination compounds of platinous halides with unsaturated substances.**—See this vol., 1369.

**Application of statistics to quantitative analysis.** A. A. BENEDETTI-PICHLER (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 373—377).—A discussion.

E. S. H.

**Calculation of mean error in conductometric titration.** J. MIKA (*Z. anal. Chem.*, 1936, 106, 248—261).—A method for the convenient calculation of the true equivalence point, subjective errors being eliminated, is developed.

J. S. A.

**Isohydric indicator method [for  $p_H$  determination].** S. STENE (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 398—399).—Modified procedure is described.

E. S. H.

**Use of adsorption indicators in acidimetry and alkalimetry.** S. N. ROY (*J. Indian Chem. Soc.*, 1936, 13, 486—487).— $\text{HNO}_3$  or  $\text{AcOH}$  can be determined by titration with  $\text{NaOH}$  in presence of  $\text{Pb}(\text{NO}_3)_2$  and fluorescein or eosin. A slight excess of alkali ppts.  $\text{Pb}(\text{OH})_2$ , which adsorbs fluorescein or eosin, giving characteristic, coloured dye complexes.

E. S. H.

**Micro-determination of active hydrogen with deuterium oxide.** R. J. WILLIAMS (*J. Amer. Chem. Soc.*, 1936, 58, 1819—1820).—The substance is dissolved in  $\text{D}_2\text{O}$ , evaporated to dryness, and the increase of wt. due to replacement of active H by D determined. Results are given for hydroxyproline and  $\text{CO}(\text{NH}_2)_2$ .

E. S. H.

**Determination of hydrogen, carbon monoxide, and methane.**—See B., 1936, 931.

**Qualitative micro-analysis by electrolysis and spectrography.** Analysis of a mine water.—See B., 1936, 1022.

**Significance of spectrum analysis for water-works.**—See B., 1936, 1022.

**Titration of chloride ion with mercuric nitrate solutions, using diphenylcarbazide indicator.** I. ROBERTS (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 365—367).—Within a definite range of  $[\text{H}^+]$ , the procedure gives an accuracy of about 0.3%.  $\text{HgO}$  can be used as a primary standard in the prep. of the  $\text{Hg}(\text{NO}_3)_2$  solutions.

E. S. H.

**Accuracy of the potentiometric iodide-silver titration.** I. M. KOLTHOFF and J. J. LINGANE (*J. Amer. Chem. Soc.*, 1936, 58, 1524—1528).—The error is 0.1% at room temp., 0.048% at 70°, and 0.017% at 90°. At the equivalence potential the ppt. con-

tains an excess of  $\text{I}^-$ , due to adsorption. Titration at 90° is recommended.

E. S. H.

**Determination of microgram quantities of iodine.** R. H. HAMILTON, jun. (*J. Amer. Chem. Soc.*, 1936, 58, 1592—1594).— $\text{IO}_3^-$  can be reduced quantitatively in hot alkaline solution by  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ . KI can be extracted with EtOH from a saturated solution of  $\text{K}_2\text{CO}_3$ .

E. S. H.

**Determination of free and combined iodine in [pharmaceutical] iodine preparations.**—See B., 1936, 1016.

**Micro-determination of iodine and iodides.** G. ENDRES and L. KAUFMANN (*Z. physiol. Chem.*, 1936, 243, 144—148).—The procedure (A., 1935, 1167) used for the determination of  $\text{NH}_2\text{OH}$  has been adapted for the determination of  $10^{-5}$ — $10^{-4}N$ -I (error about 2%) and of  $\text{I}^-$  in concns.  $>10^{-5}N$ , the concn. of the dye produced being determined by means of a photometer. In the determination of  $\text{I}^-$  the liberated  $\text{I}_2$  must be separated from excess of  $\text{I}^-$  by distillation. The concn. of the dye should be  $>2 \times 10^{-5}$  mol. per litre.

W. McC.

**Micro-determination of fluorine. Elimination of effect of chloride.** W. D. ARMSTRONG (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 384—387).—Modified procedure, based on titration with  $\text{Th}(\text{NO}_3)_4$ , but using aq. instead of alcoholic solutions, is described. The F contents of dental enamel, dentine, and inorg. phosphates have been determined.

E. S. H.

**Sodium hyposulphite solutions for the absorption of oxygen.** D. QUIGGLE (*Ind. Eng. Chem. [Anal.]*, 1936, 8, 363).— $\text{Na}_2\text{S}_2\text{O}_4$  solutions are unstable; only freshly-prepared solutions are useful for  $\text{O}_2$  absorption.

E. S. H.

**Determining oxygen in boiler-feed water.**—See B., 1936, 911.

**[Detection of] nitrous and nitric acids in drinking water.**—See B., 1936, 957.

**Determination of nitrites in presence of nitrates and of certain organic substances.**—See B., 1936, 985.

**Benzidine phosphomolybdate and its use for the colorimetric determination of phosphoric acid.** H. ETIENNE (*Bull. Soc. chim. Belg.*, 1936, 45, 516—538).—Benzidine phosphomolybdate has the formula  $3\text{C}_{12}\text{H}_{12}\text{N}_2 \cdot 2\text{H}_3\text{PO}_4 \cdot 24\text{MoO}_3 \cdot 22\text{H}_2\text{O}$ . The P is pptd. in this form in HCl solution and the ppt. is dissolved by heating with 2% aq.  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ . The resulting blue solution is matched against standards prepared from pure phosphomolybdic acid by treating with aq.  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$ . 0.2—1.5 mg. of P per 100 c.c. may be determined. As does not interfere. Details are given for the determination of P in cast Fe, steel, minerals, red Cu, and bronze.

H. J. E.

**Modifications of the Gutzeit method for determination of arsenic.** H. F. CROSSLEY (*J.S.C.I.*, 1936, 55, 272—276T).—The Gutzeit apparatus is modified by the provision of a water cooling-jacket around the staining chamber and a suitable stand to ensure rigidity. Optimum conditions have been determined.

Rapid colorimetric determination of silicon in steel.—See B., 1936, 994.

Volumetric determination of potassium by the sodium cobaltinitrite method. K. SUZUKI and M. KENJO (Rept. Govt. Sugar Exp. Sta., Formosa, 1935, No. 2, 45—55; Internat. Sugar J., 1936, 38, 270).—A modification of the Jendrassik and Takacs method (cf. A., 1935, 134) is described; the cobaltinitrite ppt. separated by centrifuging is dissolved in  $\text{H}_2\text{SO}_4$ , treated with dil. aq.  $\text{KMnO}_4$ , KI added, and the liberated I titrated with  $\text{Na}_2\text{S}_2\text{O}_3$ . J. P. O.

Determination of sodium in high aluminous material. H. V. CHURCHILL, R. W. BRIDGES, and A. L. MILLER (Ind. Eng. Chem. [Anal.], 1936, 8, 348—349).—Modified procedure, using  $\text{NH}_4\text{F}$  as fusion reagent, is described. E. S. H.

Rapid evaluation of sodium silicate.—See B., 1936, 931.

Sensitiveness of magnesium uranyl acetate reagent to sodium and potassium. C. H. GREENE (Ind. Eng. Chem. [Anal.], 1936, 8, 399—400).—The influence of the vol. ratio of reagent and test solutions and of the addition of EtOH has been investigated. E. S. H.

Determination of sodium and potassium in insoluble silicates. C. C. MILLER and F. TRAVES (J.C.S., 1936, 1390—1394).—The silicate is decomposed by the Lawrence Smith method. Na is pptd. as Na Zn uranyl acetate (cf. A., 1928, 859). Ca interferes, and double pptn. is necessary. K is determined as  $\text{KClO}_4$  after removal of Ca, Na, and  $\text{SO}_4^{2-}$ , preferably by preliminary pptn. of K Na cobaltinitrite, which is treated with  $\text{HClO}_4$ , and interfering perchlorates are extracted with  $\text{EtOAc}-\text{Bu}^\circ\text{OH}$ . A. J. E. W.

Quantitative separation of lithium, with reference to its determination in insoluble silicates. C. C. MILLER and F. TRAVES (J.C.S., 1936, 1395—1399).—Li may be determined as Li Zn uranyl acetate,  $\text{LiZn}(\text{UO}_2)_3(\text{OAc})_9 \cdot 6\text{H}_2\text{O}$ . Conditions for complete pptn. are crit. Na interferes, and is removed by extracting  $\text{LiCl}$  and  $\text{CaCl}_2$  from the mixed anhyd. chlorides with isoamyl alcohol or  $\text{COMe}_2$ ; with the former double pptn. is advisable, owing to interference of Ca when present in large quantity. A procedure is given for the determination of Na, K, and Li in silicates (cf. preceding abstract). A. J. E. W.

Qualitative analysis of the alkaline-earth and alkali groups. C. H. GREENE (Ind. Eng. Chem. [Anal.], 1936, 8, 346—348).—A system suitable for laboratory classes is described. E. S. H.

Test-tube flame test applied to the rarer elements. A. R. CLARK (J. Chem. Educ., 1936, 13, 383—384; cf. A., 1935, 1093).—Characteristic flames or residues given by Li, Rb, Cs, Au, Be, B, Sc, In, Tl, Ti, Zr, Ge, Mo, U, Se, and Te are described and sensitivities recorded. The method is especially applicable to a final identification after the usual group separations. L. S. T.

Determining hardness of water.—See B., 1936, 1022.

Qualitative analysis of the ammonia and ammonium sulphide groups and of phosphoric acid. W. FISCHER, W. DIETZ, K. BRUNGER, and H. GRIENEISEN (Angew. Chem., 1936, 49, 719—731).—An excess of Fe is added, and then aq.  $\text{NH}_3$ . The ppt. is dissolved in  $\text{HCl}$ , Fe is extracted with  $\text{Et}_2\text{O}$ , and Zr, Ti, La, and any co-pptd. Zn, Mn, Co, Ni, Ca, etc. are then pptd. with  $\text{NaOH}+\text{H}_2\text{O}_2$ . Cr, V, and U are pptd. by treating the filtrate with  $\text{HCl}$ ,  $\text{Na}_2\text{S}_2\text{O}_4$ , and  $\text{NaOH}$  successively. P and W are pptd. from the remaining solution by means of  $\text{BaCl}_2$ . Subsequent separations of the sub-groups so obtained follow usual lines. The scheme is expeditious and minimises the loss by adsorption on earlier ppts. of elements present in small amounts. J. S. A.

Analysis of cations of third and second [fourth] groups in presence of phosphate ion. V. J. PETRASCHENJ (Z. anal. Chem., 1936, 106, 241—243).—After pptn. of the second analytical group,  $(\text{NH}_4)_2\text{S}$  and  $(\text{NH}_4)_2\text{HPO}_4$  are added. The ppt. is redissolved in dil.  $\text{HCl}$ , and Cr and Mn are oxidised completely either by  $\text{Na}_2\text{CO}_3+\text{Br}-\text{H}_2\text{O}$ , or by  $\text{Na}_2\text{O}_2$ . The ppt. is treated with  $\text{AcOH}$  to dissolve Mg, Ca, Sr, and Ba. Subsequent separations are orthodox. J. S. A.

Spectrographic micro-determination of zinc. A. P. VANSELOW (Ind. Eng. Chem. [Anal.], 1936, 8, 400).—A correction (cf. this vol., 1308). E. S. H.

Electrolytic micro-determination of zinc and its application to brass. P. WENGER, C. CIMERMAN, and G. TSCHANUN. Volumetric micro-determination of zinc. C. CIMERMAN and P. WENGER (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 113—116, 116—119).—Practical details are described; calc. and experimental results are in agreement. N. M. B.

Preparation and some analytical applications of 2:7-diaminofluorine. E. L. NINO and F. CALVERT (Anal. Fis. Quím., 1934, 32, 698—701).—An improvement of the technique of Schmidt *et al.* (A., 1931, 1045) is described. The use of 2:7-diaminofluorene (I) is preferred to  $\text{H}_2\text{S}$  for detection of Cd after removal of Cu by means of  $\text{KCNS}$ . In a solution containing 0.2—0.6% of Zn with added EtOH the Zn is determined by addition of (I) in EtOH; the ppt. is dried at  $90^\circ$ . The error is  $>1$  part in 1000. (I) is suitable for the detection of blood peroxidases (cf. Schmidt *et al.*, A., 1932, 242) but not for determination of Zn in presence of Al or of Cd or Cu. F. R. G.

Cause of contamination of precipitates. II. Precipitation processes involving lead salts. Z. KARAOGLANOV (Z. anal. Chem., 1936, 106, 262—272; cf. this vol., 1220).—Further data for Pb salts are reviewed, and advanced in support of the author's theory of contamination by secondary reaction products. The known compounds  $\text{Pb}(\text{OH})\text{X}$  ( $\text{X}=\text{Cl}$ , Br, I, CNS) are considered to be such secondary products. Their formation involves the partly ionised complexes  $\text{PbX}^+$  and the degree of contamination follows the extent to which such complexes are present in solution; e.g., contamination with  $\text{PbBr}_2 > \text{PbCl}_2 > \text{Pb}(\text{CNS})_2 > \text{PbI}_2 > \text{Pb}(\text{OAc})_2 = 0$ . J. S. A.

**Determination of metallic copper in cuprous oxide-cupric oxide mixtures.** L. C. HURD and A. R. CLARK (Ind. Eng. Chem. [Anal.], 1936, 8, 380—382).— $\text{Cu}_2\text{O}$  is sol. in cold aq.  $\text{NH}_3$ ,  $\text{CuO}$  is slightly sol., and  $\text{Cu}$  insol. Addition of  $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{SO}_4$  causes reduction of any  $\text{Cu}^{++}$  entering the solution and prevents reaction between  $\text{Cu}^{++}$  and  $\text{Cu}$ . In a  $\text{CO}_2$  atm. the  $\text{Cu-CuO}$  mixture may be isolated and  $\text{Cu}$  determined by direct dissolution in  $\text{FeCl}_3 + \text{HCl}$ , followed by titration with  $\text{K}_2\text{Cr}_2\text{O}_7$ . E. S. H.

**Electrolytic application of hydrobromic acid test for copper.** G. W. BAKER (Analyst, 1936, 61, 603—604).—0.0002 mg. of  $\text{Cu}$  per sq. mm. on a steel surface may be detected by using the steel as anode, with a Pt wire cathode tipped with cotton-wool which is moistened with aq.  $\text{KBr}$ . Traces of  $\text{Cu}$  produce a purple-red stain. J. S. A.

**Determination of mercury in air and absorption of mercury vapour by means of metallic gold.** V. MAJER (Coll. Czech. Chem. Comm., 1936, 8, 339—348).—Air is passed at a known rate through glass tubing containing Au leaf. One end of the tubing is then sealed and the other drawn out into a fine capillary. On distilling, the  $\text{Hg}$  condenses in the capillary and is dissolved in  $\text{Cl}_2\text{-H}_2\text{O}$  and either determined colorimetrically or reprecipitated on Fe wire, redistilled in a fine capillary, and determined microscopically. The determination of  $\text{Hg}$  by condensing in liquid air has also been investigated. C. R. H.

**Effect of aluminium on the flame spectra of the alkaline earths. Determination of aluminium.** R. L. MITCHELL and I. M. ROBERTSON (J.S.C.I., 1936, 55, 269—272).—The presence of Al reduces the intensity of the flame emission lines of Ca and Sr. This reduction depends on the relative amounts of Ca and Sr present; with sufficient Sr in the solution, Al does not appreciably affect the Ca emission and *vice versa*. The Ca or Sr depression may be used as an indication of the amount of Al present.

**Separation and determination of aluminium and zinc.** F. H. FISHER and J. M. SMITH, jun. (Ind. Eng. Chem. [Anal.], 1936, 8, 349—350).—Al is pptd. as Li aluminate from solutions containing  $\text{NH}_4\text{OAc}$ ; Zn is determined in the filtrate as  $\text{Zn}_2\text{P}_2\text{O}_7$ . E. S. H.

**Arc spectrographic determination of indium in minerals, and association of indium with tin and silver.** F. M. BREWER and E. BAKER (J.C.S., 1936, 1286—1290).—Known sources of In are reviewed. The In content of certain Sn, Sb, Ag, Zn, Mn, and Fe minerals, and of specimens of Sn, Cd, and  $\text{CdO}$ , has been determined spectrographically by the persistence method. Sn ores, particularly sulphides (cylindrite, 0.1—1% In; franckeite, max. 0.1% In), and commercial Sn contained appreciable quantities of In, suggesting a fairly general association of In with Sn. Association in other cases is more sp. Some chalcocopyrite samples contained an estimated max. of 0.1% In. A. J. E. W.

**Chemical concentration of gallium, indium, thallium, germanium, and rhenium, in their determination in oxide and sulphide ores.**—See B., 1936, 931.

**Determination of ferrocyanide ion by means of luteocobaltamine chloride.** W. A. HYNES, M. G. MALKO, and L. K. YANOWSKI (Ind. Eng. Chem. [Anal.], 1936, 8, 356—357).— $\text{Fe}(\text{CN})_6^{4-}$  is determined by igniting the pptd.  $[\text{Co}(\text{NH}_3)_6]_4[\text{Fe}(\text{CN})_6]_3$  and weighing the residue as  $8\text{Co}_3\text{O}_4 + 9\text{Fe}_2\text{O}_3$ . The procedure is suitable in absence of  $\text{CrO}_4^{2-}$ ,  $\text{Cr}_2\text{O}_7^{2-}$ , and  $\text{VO}_3^-$ . E. S. H.

**Macro-detection of cobalt.** I. F. P. DWYER (J. Proc. Austral. Chem. Inst., 1936, 3, 239—244).—1 part of Co in presence of 1000 parts of Fe may be detected as  $(\text{NH}_4)_2\text{Co}(\text{CNS})_4$ , which may be extracted with  $\text{C}_5\text{H}_5 \cdot \text{OH} + \text{Et}_2\text{O}$ , by adding  $\text{NaNH}_4\text{HPO}_4$  until the  $\text{Fe}(\text{CNS})_3$  coloration is destroyed. Decolorisation with  $\text{KHF}_2 + \text{aq. NH}_3$  is applicable, but less sensitive. J. S. A.

**Oxidation-reduction indicators for use with dichromate.** II. S. COHEN [with R. E. OESPER] (Ind. Eng. Chem. [Anal.], 1936, 8, 364—365).—The prep. and use as indicators of  $\text{NHPh} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{Na}$ ,  $\text{NHPh} \cdot \text{C}_6\text{H}_3\text{Me} \cdot \text{SO}_3\text{Na}$ , and Na diphenylbenzidine-monosulphonate are described. E. S. H.

**Determination of chromium, vanadium, and molybdenum in silicate rocks.** E. B. SANDELL (Ind. Eng. Chem. [Anal.], 1936, 8, 336—341).—After decomp. of the rock with  $\text{Na}_2\text{CO}_3$  in the usual way, V is determined with phosphotungstic acid after separation from Cr with 8-hydroxyquinoline (I). In neutral or slightly acid solutions,  $\text{V}^{5+}$  reacts with (I) to give a compound which can be extracted from the aq. solution with  $\text{CHCl}_3$ , whereas  $\text{Cr}^{VI}$  does not react and remains in the aq. layer. Diphenylcarbazide is used as the reagent for Cr, after separation from V. Mo is determined by the  $\text{SnCl}_2\text{-KCNS-Et}_2\text{O}$  procedure without previous separation. The method is suitable for determining 0.001% of Cr or V, and 0.0001% of Mo in a 1-g. sample. E. S. H.

**Determination of chromium and iron in tanning solutions and in leather.**—See B., 1936, 948.

**Reducing action of mercury. II. Stability of quinquevalent molybdenum solutions. Determination of molybdenum by reduction with mercury and titration with ceric sulphate.** N. H. FURMAN and W. M. MURRAY, jun. (J. Amer. Chem. Soc., 1936, 58, 1689—1692; cf. this vol., 574).— $\text{Mo}^V$  solutions are sufficiently stable in air at room temp. to be used in analytical procedures which are completed in a few hr.  $\text{Mo}^{VI}$  is quantitatively reduced to  $\text{Mo}^V$  by shaking with Hg in presence of 2—3.5N-HCl.  $\text{Mo}^V$  can be titrated with  $\text{Ce}(\text{SO}_4)_2$  at room temp., using the o-phenanthroline- $\text{Fe}^{2+}$  complex indicator. E. S. H.

**Precipitation of uranium, and its separation from alkaline-earth metals by means of pyridine.** E. A. OSTROUMOV (Z. anal. Chem., 1936, 106, 244—248).— $\text{C}_5\text{H}_5\text{N}$  ppts. U quantitatively as  $\text{H}_2\text{UO}_7$  from solutions of  $\text{UO}_2^{2+}$  salts. The presence of  $\text{NH}_4$  salts is advantageous; in presence of much  $\text{SO}_4^{2-}$  a large excess of  $\text{C}_5\text{H}_5\text{N}$  is necessary. Separation from Ca, Sr, and Ba is quant. J. S. A.

**Use of nitrophenylarsinic acid as a reagent for tin.** B. TOUGARINOFF (Bull. Soc. chim. Belg., 1936, 45, 542—544).— $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_3\text{H}_2$  (0.8% aq. solu-

tion) gives a white flocculent ppt. with  $\text{Sn}^{\text{IV}}$  in  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  solution on boiling. 0.0001 g. of  $\text{Sn}$  may be detected in 20 c.c. of solution.  $\text{Hg}^{\text{II}}$ ,  $\text{Cu}$ ,  $\text{Ni}$ ,  $\text{Co}$ ,  $\text{Mn}$ ,  $\text{Fe}$ ,  $\text{Cr}$ ,  $\text{Zn}$ ,  $\text{Ba}$ ,  $\text{Sr}$ ,  $\text{Ca}$ ,  $\text{Mg}$ ,  $\text{Bi}$ , and  $\text{Sb}$  do not interfere. H. J. E.

**Colorimetric determination of titanium.** M. SCHENK (Helv. Chim. Acta, 1936, 19, 1127—1135).—Substances containing a phenolic OH give with  $\text{Ti}^{\text{IV}}$  in conc.  $\text{H}_2\text{SO}_4$  in intense red coloration. The intensity decreases with time after 2 hr. The use of  $o\text{-OH-C}_6\text{H}_4\text{-CO}_2\text{H}$  permits the determination of  $\text{Ti}$  in solutions containing 0.2—40 mg. of  $\text{TiO}_2$  per litre. The reaction is not affected by other cations, but  $\text{HNO}_3$  and  $\text{HNO}_2$  must be absent. Operative details are given. F. L. U.

**Special reaction of N. A. Tananaev and A. V. Tananaeva for zirconium.** I. P. ALIMARIN (Z. anal. Chem., 1936, 106, 276—279).—The reaction, in a more sensitive form, was described by Lundell and Knowles (A., 1920, ii, 60). J. S. A.

**Detection of minute quantities of thorium in common materials.** R. D. EVANS, G. D. FINNEY, A. F. KIP, and R. MUGELE (Physical Rev., 1935, [ii], 47, 791—792).—The Th emanation flow-technique is inherently inefficient. Four new methods involving counting of  $\alpha$ - or  $\gamma$ -rays have been developed. Applied to a series of Sierra Nevada igneous intrusive rocks they indicate that the  $\text{Th}:\text{U}$  ratio is  $>$  previously supposed. L. S. T.

**Determination of bismuth as phosphate.** W. C. BLASDALE and W. C. PARLE (Ind. Eng. Chem. [Anal.], 1936, 8, 352—353).—The procedure is accurate when pptn. is from solutions which contain no  $\text{Cl}^-$  or  $\text{SO}_4^{2-}$ , and are approx. 0.2M with respect to  $\text{HNO}_3$ , and approx. 0.065M with respect to  $(\text{NH}_4)_2\text{HPO}_4$ .  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Cu}^{2+}$ , or  $\text{Ca}^{2+}$  do not interfere;  $\text{Cd}^{2+}$  and especially  $\text{Pb}^{2+}$  interfere. Co-pptn. of basic salts is avoided by adjusting  $[\text{H}^+]$  and pptg. from a hot solution and digesting for 1 hr. at  $80^\circ$ . E. S. H.

**Separation and determination of bismuth with gallic acid.** L. KIEFT and G. C. CHANDLEE (Ind. Eng. Chem. [Anal.], 1936, 8, 392).—Pptn. with gallic acid at  $70^\circ$  serves to separate and determine  $\text{Bi}$  in 3% aq.  $\text{HNO}_3$  in presence of  $\text{Pb}$ ,  $\text{Cd}$ ,  $\text{Cu}$ ,  $\text{Zn}$ ,  $\text{Al}$ ,  $\text{Cr}$ ,  $\text{Fe}$ ,  $\text{Ni}$ ,  $\text{Ba}$ ,  $\text{Ca}$ ,  $\text{Na}$ , and  $\text{K}$ , but not  $\text{Sb}$ ,  $\text{Hg}$ ,  $\text{Sn}$ , or  $\text{Ag}$ . E. S. H.

**Analytical chemistry of tantalum, niobium, and their mineral associates.** XXXII. Phosphorus, vanadium, and a tannin precipitation series. W. R. SCHOELLER and H. W. WEBB (Analyst, 1936, 61, 585—590).—(a) Small amounts of  $\text{P}$ , carried down with  $\text{Ta}_2\text{O}_5$  and  $\text{Nb}_2\text{O}_5$  on tartaric hydrolysis, are separated by fusion with  $\text{NaOH}$  followed by extraction with aq.  $\text{NaCl}$ .  $\text{Na}_3\text{PO}_4$ , but no  $\text{Ta}$  or  $\text{Nb}$ , dissolves. (b)  $\text{V}$  may be separated from  $\text{Ti}$  and  $\text{Ta}$  by twofold pptn. with tannin (I) from  $(\text{NH}_4)_2\text{C}_2\text{O}_4$  solution half-saturated with  $\text{NH}_4\text{Cl}$ .  $\text{Ti}$  and  $\text{Ta}$  are first pptd. by (I);  $\text{V}$  only on addition of excess of  $\text{NH}_3$ . Pptn. of  $\text{Nb}$  does not occur, or is incomplete.  $\text{V}$  is separated from  $\text{Ta}$  and  $\text{Nb}$  in tartrate solution, by addition of (I)+ $\text{NH}_4\text{OAc}$  to the neutralised  $(\text{NH}_3)$  filtrate from the tartaric hydrolysis of  $\text{Ta}_2\text{O}_5$  and  $\text{Nb}_2\text{O}_5$ . The ppt. is fused with  $\text{KHSO}_4$ , extracted

with (I)+ $\text{H}_2\text{SO}_4$ , and repptd. by addition of cinchonine hydrochloride.  $\text{V}$  in the filtrate is pptd. on adding  $\text{NH}_4\text{OAc}$ . (c) Pptn. by (I), in decreasing acidity of solution, follows the order  $\text{Ta}$ ,  $\text{Ti}$ ,  $\text{Nb}$ ,  $\text{V}$ ,  $\text{Fe}$ ,  $\text{Zr}$ ,  $\text{Hf}$ ,  $\text{Th}$ ,  $\text{U}$ ,  $\text{Al}$ . Neighbouring metals cannot be separated by fractional pptn. with (I).

J. S. A.

**Determination of iridium by titration with potassium ferrocyanide.** A. A. GRUNBERG and J. L. MICHELIS (Compt. rend. Acad. Sci. U.R.S.S., 1936, 2, 179—181).—By titration in  $\text{H}_2\text{SO}_4$  solution,  $\text{Ir}^{\text{IV}}$  in the form of  $(\text{IrCl}_6)^-$  can be determined with as great accuracy as by Mohr's salt. W. R. A.

**Portable aradiant convection pyrometer.** F. T. BARR and R. F. BERGER (Ind. Eng. Chem. [Anal.], 1936, 8, 393—395).—Apparatus and technique are described. E. S. H.

**Sensitive thermo-regulator.** L. D. GOODHUE (Ind. Eng. Chem. [Anal.], 1936, 8, 387).—Sensitivity is increased by employing the principle of the differential manometer. A range of  $0.05^\circ$  is sufficient to make and break the electrical contact. E. S. H.

**Platinum resistance thermometer as a secondary temperature standard between  $14^\circ$  and  $90^\circ$  abs.** F. HENNING and J. OTTO (Physikal. Z., 1936, 37, 639—641).—For the calibration of a Pt resistance thermometer, five fixed points are required, according to the equation previously derived (this vol., 1190). Suitable points are the normal b.p. of  $\text{O}_2$ , the triple point of  $\text{H}_2$ , the normal b.p. of  $\text{H}_2$ , the triple point of  $\text{N}_2$ , and the  $\beta$ - $\gamma$  transition point of  $\text{O}_2$ . The comparison of the resistance ratios of different Pt thermometers with each other is considered. A. J. M.

**Gas furnace with temperature control.** D. VAN DUYN (Chem. Weekblad, 1936, 33, 562).—The inner tube of a van den Berg furnace (A., 1934, 162) is enclosed in a brass tube provided with a hole for carrying a thermocouple. Uniform temp. from  $500^\circ$  to  $800^\circ$  can be obtained. S. C.

**Determination of thermal expansion of liquids when observation is hindered by the temperature bath.** A. LAMBERTZ (Chem.-Ztg., 1936, 60, 755—756).—An Archimedean method is described, the change in apparent wt. of a submerged glass body being determined. J. S. A.

**Limiting sensitivity of a radiometer depending on the principle of the gas thermometer.** M. VEINGEROV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 119—122).—A radiometer operating by the thermal expansion of gas heated by incident radiation is theoretically more sensitive than other types of instrument. A. J. E. W.

**S.N.P. Photo-densimeter [photometer].** A. FAURE and PALLU (Ann. Falsif., 1936, 29, 393—401). E. C. S.

**Christiansen filters as polarisers.** H. W. FARWELL (Physical Rev., 1936, [ii], 50, 486).—Fibres of viscose and silk, wound on a frame, were used as doubly refracting crystals, and, immersed in  $\text{CS}_2$ - $\text{C}_6\text{H}_6$ , transmitted green polarised light horizontally and blue polarised perpendicularly. N. M. B.

**Frames for protecting and repairing Lovibond colour glasses.** E. FREYER (Oil and Soap, 1936, 13, 234—235).—Whole or broken glasses are mounted in light Al slide-holders, with a central window.

E. L.

**Simplified and improved cell for liquids in the interferometer.** J. W. McBAIN, T. F. FORD, and G. F. MILLS (Rev. Sci. Instr., 1936, [ii], 7, 341—342).—The cell is of block Ag, bored with two tunnels to contain the liquid and carry the light rays; it is suitable for small quantities of liquid, and evaporation difficulties are obviated.

N. M. B.

**[Quantitative] spectrum analysis using emission spectra.** J. E. MILLS (J. Proc. Austral. Chem. Inst., 1936, 3, 245—250).—The technique of the Gerlach internal standard method is described.

J. S. A.

**Apparatus for rapid study of absorption and rotatory power in the ultra-violet.** P. GESTEAU (J. Pharm. Chim., 1936, 24, [viii], 201—209).—An ultra-violet spectrograph with polariser attachments is described. It may be employed either for quant. absorption measurements or for determination of  $\alpha$ .

W. O. K.

**Anomalous diffraction gratings.** U. FANO (Physical Rev., 1936, [ii], 50, 573; cf. Wood, this vol., 128; Strong, *ibid.*, 399).—Theoretical.

N. M. B.

**Method for accurate titrations.** D. B. PALL (Canad. J. Res., 1936, 14, B, 299—300).—A colour comparator is described in which the two tubes on the one side contain  $H_2O$  and the coloured solution undergoing titration, respectively, whilst those on the other side contain a solution buffered to the required endpoint  $p_H$  and the indicator, and the original solution, without indicator, respectively. The light used is filtered to the colour of the indicator in the buffered tube. The apparatus is of particular use in titration of weak acids with weak bases in coloured solutions.

J. W. S.

**$\gamma$ -Ray sensitivity of tube counters and the measurement of the thorium content of rocks.** R. D. EVANS and R. A. MUGELE (Physical Rev., 1935, [ii], 47, 427).—Factors affecting sensitivity are discussed. The feeble  $\gamma$ -radiation from the radioactive impurities in ordinary granitic rocks can be directly measured with the highly-sensitised counters described.

L. S. T.

**Counter-controlled cloud chambers.** J. C. STREET and E. C. STEVENSON (Rev. Sci. Instr., 1936, [ii], 7, 347—353).—The design and operation of two cloud chambers of the pneumatic rubber diaphragm type are described. One is cylindrical for use with a large electromagnet, and the other is a rectangular one of wood for cosmic-ray shower studies. The expansion ratio is determined by the separation of rigid diaphragm stops.

N. M. B.

**Check valve for wash bottles.** F. H. SMITH (Ind. Eng. Chem. [Anal.], 1936, 8, 400).

E. S. H.

**Gas-absorption vessels.** W. M. MARTIN (Ind. Eng. Chem. [Anal.], 1936, 8, 395—396).—A scrubber and a quant. absorption vessel are described.

E. S. H.

**Spindle for insulating wires.** J. M. STURTEVANT (Ind. Eng. Chem. [Anal.], 1936, 8, 341).

E. S. H.

**Apparatus for production of metallic adsorption powders under nitrogen and other gases.** F. DURAU (Physikal. Z., 1936, 37, 684—688).—An apparatus for the prep. of powders of hard or soft metals for adsorption and catalysis is described.

A. J. M.

**Sensitive manostat for low pressures and its application to the adsorption of hydrogen and deuterium on copper.** T. SOLLER, S. GOLDWASSER, and R. A. BEEBE (J. Amer. Chem. Soc., 1936, 58, 1703—1706).—Apparatus for the control of gas pressures to  $\pm 0.005$  mm. at any pressure is described. Provision is made for the continuous reading of the vol. of gas entering the system during adsorption. The rates of adsorption of  $H_2$  and  $D_2$  by Cu at  $0^\circ$  and 2.63 mm. are in the ratio 3.35 : 1; the difference in activation energies of adsorption is 0.48 kg.-cal. The temp. inversion in the ratio of adsorbability of  $H_2$  and  $D_2$  has been confirmed.

E. S. H.

**Apparatus for dialysis, electrodialysis, osmosis, electro-osmosis, filtration, and electro-filtration.** MEMBRANFILTER G.M.B.H. (Chem.-Ztg., 1936, 60, 767).

E. C. S.

**Pneumatic trough.** W. H. POWERS and J. WACLAWIK (J. Chem. Educ., 1936, 13, 375).

L. S. T.

**Vacuum centrifuge.** E. G. PICKELS (Physical Rev., 1935, [ii], 47, 797).—Developments and improvements are outlined (cf. *ibid.*, 336).

L. S. T.

**Centrifuging in rotating hollow cylinders.** M. SCHLESINGER (Nature, 1936, 138, 549—550).—A new technique for the fractionation of highly disperse systems using relatively moderate centrifugal forces is described.

L. S. T.

**Hardness tester for microscopical objects.** E. M. H. LIPS and J. SACK (Nature, 1936, 138, 328—329).—Inclusions and structural elements of metallographic specimens may be identified by measurement of their hardness. A hardness tester attached to a microscope is described, and its use is illustrated by reference to a Cu-Al alloy and pearlitic cast Fe containing P.

L. S. T.

**[Small] hydrogen sulphide generator.** E. GLASGOW (J. Chem. Educ., 1936, 13, 382).

L. S. T.

**Action of fume-chambers.** E. BREZINA, W. SCHMIDT, and W. SCHWABL (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 171—178).—Observations of the behaviour of fumes in different models of fume-chambers indicate the design necessary for max. efficiency.

M. A. B.

**Approach towards the limit in the process of extraction.** C. W. GRIFFIN and M. VON SAAFF (Ind. Eng. Chem. [Anal.], 1936, 8, 358—360).—Experimental data for the extraction of solutes from one solvent by another solvent are in agreement with theoretical predictions (cf. B., 1934, 223).

E. S. H.

**Special head for Kjeldahl distillation apparatus.** C. E. WEAKLEY, jun. (Ind. Eng. Chem. [Anal.], 1936, 8, 367).

E. S. H.

Origin of modern chemical symbols and formulæ. J. R. PARTINGTON (Chem. and Ind., 1936, 759—762).

Saint Vincent de Paul and the alchemist. F. WALKER (J. Chem. Educ., 1936, 13, 353—357).  
L. S. T.

Joan Baptista van Helmont. J. R. PARTINGTON. Val Helmont's ice and water experiments. T. S. PATTERSON (Ann. Sci., 1936, 1, 359—384, 462—467).—Historical.

Natural classification of chemical substances. R. HOOYKAAS (Chem. Weekblad, 1936, 33, 599—610).—A lecture.

## Geochemistry.

Atmospheres of the fixed stars. H. LAMBRECHT and B. JUNG (Naturwiss., 1936, 24, 577—582).—A review.  
A. J. M.

Composition of the planetary nebulae. T. L. PAGE (Nature, 1936, 138, 503—504).—Relative abundances of N, O, A, Ne, and S in N.G.C. 7662 and N.G.C. 7027 have been calc. The high abundances of Ne and A relative to O are discussed.  
L. S. T.

Oxygen content of the stratosphere. E. REGENER (Nature, 1936, 138, 544).—The vol.-% of O<sub>2</sub> decreases from 20.89±0.05 at 14.5 km. to 20.39±0.05 at 28—29 km.  
L. S. T.

Ozone as a heating factor in the atmosphere. R. PENNDORF (Nature, 1936, 138, 247).—The heating effect due to O<sub>3</sub> is calc. for various atm. layers. A max. occurs at a height of 50 km. where the heating is approx. 10 times the cooling effect.  
L. S. T.

Size of atmospheric nuclei: deductions from measurements of the number of charged and uncharged nuclei at Kew observatory. H. L. WRIGHT (Proc. Physical Soc., 1936, 48, 675—689).—Formulae are discussed for determining the size of condensation nuclei from observation of the concn. in the atm. of charged and uncharged nuclei and of the no. of small ions of either sign, assuming combination by collision between small ions and uncharged nuclei to be the result of Brownian movement of the former. Assuming that the mass of a small ion is equal to that of 11 H<sub>2</sub>O mols., for R.H. <80% the nuclear radius is approx. 3×10<sup>-6</sup> cm., rising to 4.5×10<sup>-6</sup> cm. for 89% R.H. On Kohler's theory of the growth of nuclei in an atm. of increasing R.H., and if the hygroscopic nuclei are of dil. H<sub>2</sub>SO<sub>4</sub>, the mass of acid in a nucleus in summer is about 18×10<sup>-17</sup> g., and in winter 12×10<sup>-17</sup> g.  
N. M. B.

Mineral and medicinal springs of Switzerland. ANON. (Mitt. Lebensm. Hyg., 1936, 27, 49—104, 158—159, 201—203).—Analyses and physical data are recorded.

Surface waters and deep waters in the canton of Geneva. J. BUFFLE (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 129—132; cf. A., 1935, 600).—Mean vals. of the dissolved matter, alkalinity, CaO, and SO<sub>3</sub> of H<sub>2</sub>O from wells in different localities and over intervals of 4—27 years are given and discussed.  
N. M. B.

Petrographic nomenclature. A. K. WELLS (Geol. Mag., 1936, 73, 319—325).—Recommendations made by the British Association Committee, 1932, are summarised.  
L. S. T.

Geologic deductions from a thermal equation. J. S. DELURY (J. Geol., 1936, 44, 479—495).—A thermal source is indicated for the energy of earth distortion and deformation of the outer lithosphere. Heat is effective for these purposes in direct proportion to the unevenness of its distribution. Radioactive elements, which are regarded as the most important source of heat in outer shells, migrate extensively in geologic time through erosion and movements of magma. Small differences in thermal conductivity and in distribution of radioactive elements lead to large differences in geothermal history.  
L. S. T.

Contrasted differentiation. A. HOLMES (Geol. Mag., 1936, 73, 228—238).—Critical (cf. Nockolds, *ibid.*, 1934, 71, 31).  
L. S. T.

Differentiated dyke of Newmains, Dumfriesshire, and its contact and contamination phenomena. W. Q. KENNEDY and H. H. READ (Quart. J. Geol. Soc., 1936, 92, 116—145).—In the granophyric spessartite or markfieldite dyke at Newmains the crystallisation of quartz arises from the breaking-up of plagioclase into albite, epidote, and white mica at a late stage in the consolidation history of the rock. Normal markfieldite is differentiated into basic markfieldite and markfieldite-pegmatite by fractional crystallisation and filter-pressing effect. The junctions of the normal markfieldite against the country rock, a calcareous greywacke, are sharp. Where the markfieldite-pegmatite is in contact with the greywacke, contamination has occurred. This involves a reciprocal reaction whereby the markfieldite-pegmatite loses Al<sub>2</sub>O<sub>3</sub>, Na<sub>2</sub>O, and K<sub>2</sub>O, and gains Fe, MgO, and CaO. The chemistry of the contamination process and its influence on the course of mafic crystallisation are discussed. Analyses of the rocks concerned are recorded.  
L. S. T.

Progressive kinetic metamorphism in the Missi Series near Flinflon, Manitoba. J. W. AMBROSE (Amer. J. Sci., 1936, [v], 32, 257—286).—Pre-Cambrian greywackes and conglomerates show three zones of progressive metamorphism characterised respectively by chlorite, biotite, and garnet. Intruded igneous rocks in the series are also affected in a like degree. These zones are related to the intensity of shearing of the rocks, and it is suggested that the heat developed by this shearing was sufficient to cause the metamorphism.  
L. J. S.

Minerals in Bates limestone, Lewiston, Maine. L. W. FISHER (Amer. Min., 1936, 21, 321—326).—Igneous intrusions of different types are described. The mineral associations observed in different zones

suggest that the Bates limestone was originally an impure  $\text{MgCO}_3$  formation. Mineralogical changes produced by various types of metamorphism are described. L. S.-T.

**Bore-hole investigations in Yellowstone Park.** C. N. FENNER (J. Geol., 1936, 44, 225—315).—The structural features of the cores have been examined and temp. and pressures measured. The mineralogy and petrology of cores from various depths are described in detail, and chemical changes which have occurred are discussed. New analyses are recorded. L. S. T.

**Geology of a portion of the Savant Lake area, Ontario.** G. RITTENHOUSE (J. Geol., 1936, 44, 451—478).—The genesis of two Fe-bearing formations is discussed. L. S. T.

**Optics and structure of three-dimensional spherulites.** H. W. MORSE and J. D. H. DONNAY (Amer. Min., 1936, 21, 391—426).—The shape and optical properties of artificial spherulites and related aggregates, mainly carbonates, grown by diffusion and metathesis in gelatin have been further investigated (cf. A., 1933, 691). In spite of wide variations in external shape, most of these aggregates belong to the same type of aggregation, due to radiating crystallisation. A mechanism of formation of spherulitic structures is discussed. L. S. T.

(A) Nature of the invisible gold contained in pyrites. (B) Secondary transformations and enrichment of gold in its primary deposits. G. BÜRG (Z. pr. Geol., 1935, 43, 17—26, 65—75, 89—94; Chem. Zentr., 1935, ii, 3897).—(A) The solubility of Au in the system Fe-S decreases as the S content is decreased. On heating the Au enters the pyrites lattice. At 1 atm. the Au-S compounds formed are stable up to 200°. At higher pressures they are stable to 600°. H. J. E.

**Microstructures and metallisation of the gold-quartz veins of Cornucopia, Oregon.** G. E. GOODSPEED (Econ. Geol., 1936, 31, 398—416). L. S. T.

**Quartz from Bavena.** P. GALLITELLI (Period. Min., 1935, 6, 105—128; Chem. Zentr., 1935, ii, 3896).—Data are given of the characteristic habit of quartz from Bavena. It is concluded that the quartz was formed at <575°, and separated before the minerals of the pneumatolytic phase. J. S. A.

**Relation of the granite-gneiss and the schists and quartzites in W. Africa.** P. LEGOUX (Compt. rend., 1936, 202, 2090—2092).—A discussion. H. J. E.

**Minerals of Bavena granite: fayalite.** E. GRILL (Period. Min., 1935, 6, 129—133; Chem. Zentr., 1935, ii, 3896).—Inclusions are identified as partly oxidised fayalite. J. S. A.

**Epidotite from Acceglio (Valle Maira).** R. RONDOLINO (Period. Min., 1935, 6, 153—167; Chem. Zentr., 1935, ii, 3896). J. S. A.

**Copper deposits of the Southern Appalachian region.** C. N. FENNER (Econ. Geol., 1935, 30, 928—936).—A discussion of the views of Ross (U.S. Geol. Survey, Prof. Paper 179, 1935). L. S. T.

**Copper deposits of the Southern Appalachian region.** C. S. ROSS (Econ. Geol., 1936, 31, 428—432).—A reply to criticism (cf. preceding abstract). L. S. T.

**Supergene sphalerite, galena, and willemite at Balmat, N.Y.** J. S. BROWN (Econ. Geol., 1936, 31, 331—354).—The occurrence of willemite, chlorite, hæmatite, ilvaite, and magnetite, and of a second generation of sphalerite, galena, and chalcopyrite, believed to be of supergene origin, is described. L. S. T.

**Asbestos deposits of Thetford district, Quebec.** H. C. COOKE (Econ. Geol., 1936, 31, 355—376).—The geological setting of the deposits is outlined and the relation of the asbestos veins to faults is described. Theories of origin of the veins are discussed. L. S. T.

**Nodular, orbicular, and banded chromite in northern California.** W. D. JOHNSTON, jun. (Econ. Geol., 1936, 31, 417—427).—The minerals are described and analyses are given. The genetic significance of the structures is briefly discussed. L. S. T.

**Possible age of monazite from Mars Hill, N. Carolina.** J. P. MARBLE (Amer. Min., 1936, 21, 456—457).—The monazite crystal described by Schaller (A., 1934, 628) contains Pb 0.152—0.175, Th 5.526—5.596, and U 0.016—0.019%; approx. age  $584 \times 10^6$  years. L. S. T.

**Structure and chemical composition of greenalite.** J. W. GRUNER (Amer. Min., 1936, 21, 449—455).—The X-ray diagrams of greenalite (I) from the Fe formation of the Mesabi Range indicate that it is similar in structure to serpentine. The formula approximates to  $9\text{FeO} \cdot \text{Fe}_2\text{O}_3 \cdot 8\text{SiO}_2 \cdot \text{H}_2\text{O}$  or  $(\text{OH})_{12}\text{Fe}^{\text{II}}_9\text{Fe}^{\text{III}}_2\text{Si}_8\text{O}_{22} \cdot 2\text{H}_2\text{O}$ . The ratio  $\text{Fe}_2\text{O}_3 : \text{FeO}$  varies considerably and some MgO usually replaces FeO. (I) is actually anisotropic, but appears to be isotropic on account of its fineness of grain and dark colour. L. S. T.

**Crystallographic data, unit cell, and space-group for berthierite ( $\text{FeSb}_2\text{S}_4$ ).** M. J. BUEGER (Amer. Min., 1936, 21, 442—448; cf. *ibid.*, 205).—The Weissenberg method gives  $a$  11.44,  $b$  14.12,  $c$  3.76 Å; space-group  $Pnam$  ( $V_s^{10}$ ); 4  $\text{FeSb}_2\text{S}_4$  per unit cell. L. S. T.

**Two monzonitic series of the Newry complex.** D. L. REYNOLDS (Geol. Mag., 1936, 73, 337—364; cf. A., 1935, 1100).—Analyses and petrographic descriptions of olivine-monzonite and syenite are given. The two converging monzonitic series in the hybrids of Seeconnell, and their relationships, are established on a chemical basis. L. S. T.

**Enderbite, a new member of the charnockite series.** C. E. TILLEY (Geol. Mag., 1936, 73, 312—316).—The name *enderbite* is suggested for an acid member of the charnockite series characterised by rhombic pyroxene in which plagioclase (oligoclase or andesine) is the essential felspar. Enderbite from Proclamation Island, Enderby Land, Antarctica, has  $\text{SiO}_2$  75.50,  $\text{Al}_2\text{O}_3$  13.92,  $\text{Fe}_2\text{O}_3$  0.48,  $\text{FeO}$  1.17,  $\text{MgO}$  0.52,  $\text{CaO}$  3.54,  $\text{Na}_2\text{O}$  3.64,  $\text{K}_2\text{O}$  0.74,  $\text{P}_2\text{O}_5$  none,  $\text{TiO}_2$  0.08,  $\text{MnO}$  none,  $\text{H}_2\text{O}$ —0.30,  $\text{H}_2\text{O}+$  0.15, total 100.04%;  $d$  2.67. L. S. T.

**Origin of the Salton volcanic domes, Salton Sea, California.** V. C. KELLEY and J. L. SOSKE (J. Geol., 1936, 44, 496—509). L. S. T.

**Datolite and herderite.** H. STRUNZ (Z. Krist., 1936, 93, 146—150).—Herderite,  $\text{Ca}(\text{F},\text{OH})\text{BePO}_4$ , is monoclinic prismatic,  $a_0$  4.80,  $b_0$  7.68,  $c_0$  9.80 Å,  $\beta$  90° 6', space-group  $C_{2h}^2$ , and is thus isomorphous with the silicate datolite,  $\text{Ca}(\text{OH})\text{BSiO}_4$ . A probable structure is discussed. B. W. R.

**Analcite rock from Cloudy Bay, Marlborough, New Zealand** J. A. BARTRUM (New Zealand J. Sci. Tech., 1936, 18, 120—123).—The shapes of the abundant large crystals of analcite (I) in the tinguaita described indicate that earlier phenocrysts of nepheline had been replaced by (I) before the rock solidified. After the magma had been injected into fissures (I) crystallised conjointly with ægirine-augite from the aq. magma to form the felted matrix in which the phenocrystic minerals are embedded. A. G. P.

**Eulysites and related rock types from Loch Duich, Ross-shire.** C. E. TILLEY (Min. Mag., 1936, 24, 331—342).—Eulysite (a type not previously recognised in the British Isles) is a dense rock composed of fayalite, hedenbergite, iron-hypersthene, garnet, magnetite, and apatite. Chemical analyses are given of this and of related hedenbergite-garnet-magnetite-rock and grunerite-garnet-magnetite-rock. These rocks have probably been formed by the

metamorphism of sediments rich in Fe and  $\text{SiO}_2$ , i.e., siliceous Fe ores. L. J. S.

**Effects of heat on the optical orientation of plagioclase feldspars.** C. T. BARBER (Min. Mag., 1936, 24, 343—352).—Feldspars of different composition after heating at 1000° show no appreciable change in the optical orientation and the optic axial angle. L. J. S.

**Reciprocal rôle of alumina in reaction series.** A. BRAMMALL (Min. Mag., 1936, 24, 362—366).—The immiscibility gap in the clinoenstatite-diopside series is related to the (NaSi)–(CaAl) replacement in the plagioclase series, the rôle of Al atoms in the two series being reciprocal. L. J. S.

**Chlorophyll and hæmin derivatives in organic minerals.** A. TREIBS (Angew. Chem., 1936, 49, 682—686).—A review (cf. A., 1935, 727). F. O. H.

**Alterations of nitrogen content of organic substances during and after deposition.** K. KREJCI-GRAF (Z. pr. Geol., 1935, 43, 97—101; Chem. Zentr., 1935, ii, 3753).—The disappearance of N in sapropel corresponds with the conditions of decomp. in marine deposits. The ratio C:N affords no evidence of the age of sedimentary deposits. J. S. A.

**Selenium in Hawaii [soils] and its probable source in the United States.**—See B., 1936, 986.

**Selenium compounds in soils.**—See B., 1936, 1011.

## Organic Chemistry.

**Algebraic calculation of the numbers of isomerides of certain organic compounds.** G. POLYA (Z. Krist., 1936, 93, 415—443).—Mathematical. The "symmetry formula" for the basic substance is fundamental; from it by simple algebraic substitution the no. of possible isomerides of various types is directly derived. Formulæ are summarised for the chief org. series. B. W. R.

**Steric hindrance.** E. DE ROY VAN ZUYDEWIJN and J. STUURMAN (Chem. Weekblad, 1936, 33, 540—542).—From a theoretical discussion it is concluded that steric hindrance, although highly probable in some cases, is not yet proved. It is doubtful whether deceleration of a reaction by surrounding the functional group with substituents is purely a question of spatial configuration. S. C.

**Reactions of deuterium atoms with methane and ethane.**—See this vol., 1344.

**Dehydrogenating cracking of ethane.** P. FERRERO and E. DELTOMBE (Bull. Soc. chim. Belg., 1936, 45, 455—492).—The reaction was studied by a flow method at 700—1250°/0.1—1 atm. The main reaction is a decomp. into  $\text{C}_2\text{H}_4$  and  $\text{H}_2$ . The  $\text{C}_2\text{H}_4$  is a max. at 900—950° and the proportion formed increases with the rate of flow.  $\text{CH}_4$  is formed in a secondary reaction which entails Me radicals, and increases with rise in temp.  $\text{C}_2\text{H}_2$  is formed by decomp. of  $\text{C}_2\text{H}_4$  at >830°. Small amounts of liquid

products (max., approx. 25% of  $\text{C}_2\text{H}_6$  decomposed) were formed. These were polymerisation products derived from butadiene and  $\text{C}_2\text{H}_2$ , formed by the dehydrogenation of  $\text{C}_2\text{H}_4$ , and varied in composition between  $\text{C}_n\text{H}_{1-3n}$  and  $\text{C}_n\text{H}_{1-6n}$ . H. J. E.

**Action of ultra-violet light on halogenated hydrocarbons.** II. E. MULLER and K. EHRLMANN (Ber., 1936, 69, [B], 2207—2210; cf. A., 1932, 830).—Prolonged irradiation of  $(\cdot\text{CHCl}_2)_2$  with passage of dry  $\text{N}_2$  does not lead to elimination of HCl or other marked change. The production of  $\text{CHCl}_2\cdot\text{COCl}$  in presence of air (*loc. cit.*) therefore proceeds  $(\cdot\text{CHCl}_2)_2 \rightarrow \text{CHCl}_2\cdot\text{CCl}_2\cdot\text{OH} \rightarrow \text{CHCl}_2\cdot\text{COCl}$ . Under these conditions  $\text{CHCl}_3$  and  $\text{C}_2\text{HCl}_3$  remain unchanged.  $(\cdot\text{CH}_2\text{Cl})_2$  does not appreciably absorb ultra-violet light, but is relatively greatly changed thereby in presence of air. The production of  $(\cdot\text{CCl}_2\cdot\text{CHCl}_2)_2$  is attributed to the action of excited O. No part is played by O in the conversion of  $\text{C}_2\text{H}_2\text{Cl}_4$  into  $\text{C}_2\text{HCl}_3$  by boiling alkali since a precisely similar effect is produced by boiling anhyd.  $\text{C}_5\text{H}_5\text{N}$ . Irradiation with light of short  $\lambda$  in presence of  $\text{O}_2$  converts  $(\cdot\text{CH}_2\text{Cl})_2$  into  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$ ,  $\text{C}_2\text{HCl}_3$  smoothly into  $\text{CCl}_2\cdot\text{COCl}$ , and  $\text{C}_2\text{HCl}_3$  into  $\text{CHCl}_2\cdot\text{COCl}$  with traces of HCl.  $\text{CH}_2\cdot\text{CCl}_2$  and  $(\cdot\text{CHCl})_2$  evolve much HCl (even in  $\text{N}_2$ ) and give resinous products. Under the experimental conditions,  $\text{COCl}_2$  is not obtained from ethylenic compounds.  $\text{PhCl}$  is unchanged when irradiated in presence of  $\text{O}_2$ .  $\text{CH}_2\text{PhCl}$  passes slowly

into BzOH with probable intermediate formation of PhCHO.  $\text{CHPhCl}_2$  rapidly and completely gives BzCl. H. W.

**Organic laboratory chemistry. VI—VIII.** E. F. DEGERING (J. Chem. Educ., 1936, 13, 377—382).—Methods for the prep. of  $(\text{CH}_2\text{Br})_2$  and  $\text{NH}_2\text{Ph}$  are detailed. Various pieces of apparatus are described. L. S. T.

**Ozonisation of triple linkings.** C. D. HURD and R. E. CHRIST (J. Org. Chem., 1936, 1, 141—145).— $\text{CPh:C}\cdot\text{CO}_2\text{H}$ ,  $\text{CPh:CH}$ ,  $\Delta^4$ -hexinene (details for large-scale prep. of pure hydrocarbon given),  $\Delta^4$ -heptinene, 1-ethynylcyclohexan-1-ol, and ethynylfenchyl alcohol on ozonolysis with 5 and 10%  $\text{O}_3$  in  $\text{CCl}_4$  followed by hydrolysis of the resulting ozonides give rise to the acids expected on cleavage of the triple linkings in 42, 59, 51, 59, 52, and 61% yield, respectively. H. G. M.

**Proposed mechanism for mercury catalysis in acetylene addition reactions.** G. F. HENNION, R. R. VOGT, and J. A. NIEUWLAND (J. Org. Chem., 1936, 1, 159—162).—A scheme involving the formation of a highly reactive intermediate compound,  $\text{R}\cdot\text{C}(\text{OB})\cdot\text{CR}'\cdot\text{HgA}$ , during the addition in presence of  $\text{HgA}_2$  of BOH (B=H, alkyl, acyl, aryl, etc.) to an acetylene  $\text{CR:CR}'$  to form  $\text{R}\cdot\text{CH}_2\cdot\text{CR}'(\text{OB})_2$  is advanced, and shown to be in accord with, but not proved by, the known facts. H. G. M.

**Reactions of alkylacetylenes. XIV. Reaction of butylacetylene with hydrogen bromide.** C. A. YOUNG, R. R. VOGT, and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 1806—1808).—Addition of HBr to  $\text{CH}\cdot\text{CBu}$  (I) containing an appreciable amount of peroxides (II) [derived from (I)] occurs rapidly at  $0^\circ$  and gives varying amounts (according to time and amount of HBr) of  $\alpha$ -bromo- $\Delta^4$ -hexene (III) and  $\alpha$ - $\beta$ -dibromohexane (IV). In absence of (II) reaction occurs much more slowly; thus (I) and HBr ( $>2$  mols.) in presence of quinol and  $\text{FeBr}_2$  [which rapidly destroys (II)] at  $15^\circ/12$  hr. afford  $\beta$ -bromo- $\Delta^4$ -hexene (V),  $\beta$ - $\beta$ -dibromohexane (VI), b.p.  $83.5\text{--}84^\circ/24$  mm. [hydrolysed ( $\text{Ag}_2\text{SO}_4$  in 10%  $\text{H}_2\text{SO}_4$ ) to  $\text{CMeBu}$ ], a little (III), and much unchanged (I). (III) and (V) also react rapidly with HBr in presence of (II) to give (IV); in absence of (II), (III) yields a little (IV), whilst (V) affords (IV) and (mainly) (VI). H. B.

**Acetylene polymerides and their derivatives. XXVI. Reaction of halogeno-ethers with vinylacetylene.** H. B. DYKSTRA (J. Amer. Chem. Soc., 1936, 58, 1747—1749).— $\text{CH}_2\cdot\text{CH}\cdot\text{C}\cdot\text{CH}$  (I),  $\text{CH}_2\text{Cl}\cdot\text{OMe}$ , and  $\text{BiCl}_3$  in  $\text{Et}_2\text{O}$ -pyrogallol (antioxidant) at  $5\text{--}15^\circ$  give mainly  $\alpha$ -chloro- $\varepsilon$ -methoxy- $\Delta^4$ -pentadiene (II), b.p.  $60\text{--}61^\circ/10$  mm. (presumably formed by a 1:4-addition), and some  $\gamma$ -chloro- $\varepsilon$ -methoxy- $\Delta^4$ -pentadiene (III), b.p.  $46^\circ/10$  mm. (II) rearranges to (III) when treated with  $\text{CuCl}$  and 18%  $\text{HCl}$  in  $\text{Et}_2\text{O}$  at  $20\text{--}40^\circ$ . (II) and (III) are oxidised ( $\text{KMnO}_4$ ) to  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$  and  $\text{OMe}\cdot\text{CHCl}_2\cdot\text{CO}_2\text{H}$ , respectively. (III) and maleic anhydride in  $\text{COMe}$ , at  $50^\circ$  give (after hydrolysis with  $\text{H}_2\text{O}$ ) 4-chloro-3-methoxymethyl- $\Delta^4$ -tetrahydrophthalic acid, m.p.  $163\text{--}165^\circ$ ; (II) does not react. (III) polymerises (rate accelerated by light, heat, and catalysts) to a rubber-like resin.  $\gamma$ -Chloro- $\varepsilon$ -ethoxy-

b.p.  $44^\circ/4$  mm., and  $\varepsilon$ -butoxy-, b.p.  $67^\circ/2$  mm.,  $\Delta^4$ -hexadienes and  $\alpha$ -chloro- $\varepsilon$ -ethoxy-, b.p.  $56^\circ/4$  mm., and  $\varepsilon$ -butoxy-, b.p.  $79^\circ/2$  mm.,  $\Delta^4$ -hexadienes are similarly prepared from (I) and the appropriate  $\text{OAlk}\cdot\text{CHMeCl}$ . H. B.

**Substitution of fluorine for other halogens by use of mercurous fluoride and iodine. Preparation of methyl fluoride.** F. SWARTS (Bull. Acad. roy. Belg., 1936, [v], 22, 781—783).—On the basis of a mechanism previously indicated (this vol., 712)  $\text{MeF}$  is prepared in 80% yield by gradual addition of  $\text{Hg}_2\text{F}_2$  (1 mol.) to  $\text{I}$  (1 mol.) in  $\text{MeI}$  ( $>2$  mols.). J. T. A.

**Condensations by sodium. VII. General method for stopping the Wurtz reaction at the intermediate organometallic stages.** A. A. MORTON and I. HECHENBLEIKNER (J. Amer. Chem. Soc., 1936, 58, 1697—1701; cf. this vol., 966).—Addition of  $n$ -amyl chloride to Na powder (excess) in  $\text{C}_5\text{H}_{12}$  or light petroleum at  $0\text{--}38^\circ$  and subsequent treatment (after initial reaction ceases) with  $\text{CO}_2$  gives  $\text{C}_5\text{H}_{11}\cdot\text{CO}_2\text{H}$  (22—44.2%) and  $\text{CHBu}(\text{CO}_2\text{H})_2$  (I) (8—24%). Analogous results are obtained with (in order of decreasing yield)  $n$ -hexyl chloride,  $\text{PhCl}$ ,  $\text{Bu}^n\text{Cl}$  ( $\text{Bu}^n\text{Br}$ ), *tert*-amyl chloride,  $\beta$ -chloro- $\gamma$ -methylbutane, and  $\text{Pr}^n\text{Cl}$ . Evidence indicating that (I) is not formed by way of  $\text{C}_5\text{H}_{11}\cdot\text{Na}$  is discussed.  $\text{C}_5\text{H}_{10}\text{Na}_2$  has a greater thermal stability than  $\text{C}_5\text{H}_{11}\text{Na}$ . H. B.

**Determination of alcohol by Widmark's method.** E. FLOTOW and G. NAUENBURG (Pharm. Zentr., 1936, 77, 580—581).—An automatic pipette is described for delivering a fixed vol. of  $\text{H}_2\text{SO}_4\text{--CrO}_3$  during this determination. Distillation is replaced by keeping overnight, which obviates some causes of inaccuracy. R. S. C.

**New types of racemisation reactions.** E. BERGMANN and A. BONDI (J. Amer. Chem. Soc., 1936, 58, 1814).—The formation of  $(-)\beta$ -methyl- $\alpha$ -diethyl- $n$ -amyl alcohol, b.p.  $92\text{--}93^\circ/32$  mm.,  $[\alpha]_D^{25} -13.04^\circ$  in  $\text{COMe}_2$ , from  $l\text{-CHMePr}^+\cdot\text{CO}_2\text{Me}$  (I) and  $\text{MgEtBr}$  supports the suggestion (A., 1935, 1223) that  $dl\text{-CHMePr}^+\cdot\text{CPh}_2\cdot\text{OH}$  [from (I) and  $\text{MgPhBr}$ ] results owing to the equilibrium  $\text{CHMePr}^+\cdot\text{CPh}_2\cdot\text{OH} \rightleftharpoons \text{H}_2\text{O} + \text{CMePr}^+\cdot\text{CPh}_2$ . These results are in accordance with the greater ease of dehydration of  $\text{CPh}_2\text{Alk}\cdot\text{OH}$  than  $\text{CAlk}_3\cdot\text{OH}$ . The racemisation of  $\beta$ -bromohexane during its conversion into the Grignard reagent (Porter, *ibid.*, 1228) is probably due to the racemisation of the  $\text{MgRBr}$  by  $\text{Br}^+$ ; the reaction is analogous to the racemisation of  $\text{CHPhMeCl}$  by interaction with  $\text{Mg}$  or  $\text{Na}$  (cf. A., 1933, 574; this vol., 803). H. B.

**$\beta$ -Amyloxyethyl esters of  $p$ -aminobenzoic acid.** H. V. ASHBURN, A. R. COLLETT, and C. L. LAZZELL (J. Amer. Chem. Soc., 1936, 58, 1549—1551).—The requisite  $\text{C}_5\text{H}_{11}\cdot\text{OH}$  (20—30 mols.),  $(\text{CH}_2)_2\text{O}$  (7 mols.), and conc.  $\text{H}_2\text{SO}_4$  (1 c.c.) [or, for (I),  $\text{Al H}$  silicofluoride] at  $130\text{--}150^\circ$  give  $\beta$ - $n$ -amyl-, b.p.  $188.3^\circ/751.1$  mm.,  $\beta$ -isoamyl-, b.p.  $179.8^\circ/750.1$  mm.,  $\beta$ - $\beta'$ -methylbutyl-, b.p.  $176.8^\circ/748$  mm.,  $\beta$ - $\alpha'$ -ethylpropyl-, b.p.  $172.6^\circ/746.4$  mm.,  $\beta$ - $\alpha'$ -methylbutyl-, b.p.  $173.8^\circ/746$  mm., and  $\beta$ - $\alpha$ - $\alpha$ -dimethyl-

propyl- (I), b.p. 168.4°/745.4 mm., -oxyethyl alcohols; the p-nitrobenzoates (prep.: A., 1933, 48) have b.p. 191.5—192.5°/4 mm. (II), 184.1—185.1°/4 mm., 188.1—189°/4 mm., 183—184°/4 mm., 186.6—187.6°/4 mm. (m.p. 74.5°), and 164—166°/0.42 mm., respectively, and are reduced (method: A., 1935, 1494) to the p-aminobenzoates [that from (II) has m.p. 56.8°; others are viscous oils] (picramides, m.p. 115.5°, 140.9°, 129.1°, 136°, 120.8°, and 134.9°, respectively).

H. B.

Influence of nitric oxide on thermal decomposition of dimethyl ether.—See this vol., 1346.

Decomposition of n-butyl nitrite.—See this vol., 1344.

Reactions relating to carbohydrates and polysaccharides. XLIX. Mol. wt., molar refraction, f.p., and other properties of polyethylene glycols and their derivatives. A. F. GALLAUGHER and H. HIBBERT (J. Amer. Chem. Soc., 1936, 58, 813—816; cf. this vol., 963).—The mol. wts. of tri- (I), b.p. 115.5—117°/0.1 mm., f.p. -9.4°, tetra- (II), b.p. 144—145.5°/0.1 mm., f.p. -9.4°, penta-, b.p. 174—176°/0.14 mm., f.p. -8.7°, hexa-, b.p. 203—205°/0.3 mm. f.p. 1.3°, and hepta-, b.p. 241—244°/0.6 mm., f.p. 7.7°, -ethylene glycols, tetraethylene glycol monochlorohydrin (III), b.p. 134.6—136°/0.94 mm., f.p. -54° [by-product during reaction of Na derivative of diethylene glycol (f.p. -10.1°) and (CH<sub>2</sub>Cl-CH<sub>2</sub>)<sub>2</sub>O (IV)], and diethylene glycol Me<sub>2</sub> ether [ββ'-dimethoxydiethyl ether] (V), b.p. 160.5—161°/756.6 mm. [formed (cf. Cretcher and Pittenger, A., 1925, i, 228) together with a little CH<sub>2</sub>-CH-O-CH<sub>2</sub>-CH<sub>2</sub>-OMe from (IV) and MeOH-NaOMe at about 25°], are determined cryoscopically in C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>. The vals. for (I), (II), (III), and (V) increase regularly with rise in concn.; in the other cases, association is very large at low concns., then decreases to a min., and finally increases. The glycols show an approx. const. increase in mol. refraction with rise in mol. wt. C<sub>2</sub>H<sub>4</sub>(OH)<sub>2</sub>, f.p. -13.2°, (CH<sub>2</sub>)<sub>3</sub>(OH)<sub>2</sub>, f.p. -32°, and (in a smaller degree) s-C<sub>2</sub>H<sub>4</sub>Cl<sub>2</sub> and OMe-CH<sub>2</sub>-CH<sub>2</sub>-OH appear to form co-ordination compounds with anhyd. CuSO<sub>4</sub>.

H. B.

Esters of perchloric acid. J. MEYER and W. SPORMANN (Z. anorg. Chem., 1936, 228, 341—351).—Me perchlorate, b.p. 52°, EtClO<sub>4</sub>, and Pr<sup>n</sup> perchlorate, b.p. 89°, can be prepared by distilling a mixture of R<sub>2</sub>Ba(SO<sub>4</sub>)<sub>2</sub> (R=Me, Et, or Pr) and Ba(ClO<sub>4</sub>)<sub>2</sub> into anhyd. Et<sub>2</sub>O containing anhyd. CuSO<sub>4</sub>, and removing the Et<sub>2</sub>O by evaporation. EtClO<sub>4</sub> has also been obtained by very slow addition of anhyd. HClO<sub>4</sub> to EtOH, and MeClO<sub>4</sub> and EtClO<sub>4</sub> by treatment of anhyd. AgClO<sub>4</sub> with RBr in abs. EtOH. MeClO<sub>4</sub> is also produced by treating anhyd. HClO<sub>4</sub> with CH<sub>3</sub>N<sub>2</sub>. All three compounds explode readily on heating, percussion, or friction. They are readily sol. in Et<sub>2</sub>O and EtOH and insol. in H<sub>2</sub>O, but are gradually hydrolysed by the latter, the readiness of hydrolysis following the order MeClO<sub>4</sub>>EtClO<sub>4</sub>>PrClO<sub>4</sub>.

J. W. S.

Attempts to prepare cyclic glycerides. Preparation of "tetrachlorodiglycerides" of dicarboxylic acids. M. GOSWAMI and A. SHAHA (J.

Indian Chem. Soc., 1936, 13, 464—466).—Glycerol, the dibasic acid, and POCl<sub>3</sub> at 100° give di-ββ'-dichloroisopropyl succinate, b.p. 141—142°/4 mm., maleate, b.p. 128—130°/4 mm., citraconate, b.p. 228—232°/4 mm., and phthalate (I) [from the anhydride (II)], b.p. 260—262°/4 mm. (I) is also obtained from (CH<sub>2</sub>Cl)<sub>2</sub>CH-OH, (II), and POCl<sub>3</sub>.

Oxidation of formic acid.—See this vol., 1348.

Photolysis of acetic and formic acids.—See this vol., 1349.

Thermal decomposition of the silver salts of carboxylic acids. III. Thermal decomposition of the silver salts of acetic and benzoic acid. S. J. KANEVSKAJA and M. M. SCHEMJAKIN (Ber., 1936, 69, [B], 2152—2157; cf. this vol., 469).—Thermal decomp. of AgOAc affords Ac<sub>2</sub>O and large amounts of AcOH, whilst Bz<sub>2</sub>O, PhOBz, BzOH, and a small amount of PhOH but not C<sub>6</sub>H<sub>6</sub> are derived from AgOBz. In all cases the initial change appears to be decomp. into Ag<sub>2</sub>O and the acid anhydride. Subsequently hydration occurs due to H<sub>2</sub>O present in the Ag salt or formed by destructive decomp. of the initial acid. PhOH is attributed to the oxidation by Ag<sub>2</sub>O of C<sub>6</sub>H<sub>6</sub> or Ph formed by thermal decomp. of the anhydride and PhOBz results from nascent PhOH and unchanged Bz<sub>2</sub>O.

Fluorination of organic compounds. II. P. C. RAY and A. C. RAY (J. Indian Chem. Soc., 1936, 13, 427—428; cf. A., 1935, 733).—CH<sub>2</sub>F-CO<sub>2</sub>Me, CH<sub>2</sub>F-CO<sub>2</sub>Et, and CH<sub>2</sub>PhF are prepared from the Br-compounds by TiF<sub>2</sub> in hot abs. EtOH. The method is not general, eight compounds failing to react and others not giving pure F-derivatives.

R. S. C.

Configurative relationship of disubstituted acetic and propionic acids containing an ethyl group. P. A. LEVENE, A. ROTHEN, and G. M. MEYER (J. Biol. Chem., 1936, 115, 401—413).—By conversion into hydrocarbons it is shown that configuratively related acids, CHETPr-CO<sub>2</sub>H (I), CHETPr'-CO<sub>2</sub>H, and CHMeR-CO<sub>2</sub>H, rotate in the same direction and that related acids, (I) and CHETPr-CH<sub>2</sub>-CO<sub>2</sub>H (II), rotate in opposite directions. The previous correlation (A., 1931, 821) of l-CHETPr-CH<sub>2</sub>-CO<sub>2</sub>H with d-CHETBu-CH<sub>2</sub>-CO<sub>2</sub>H is erroneous. The rotatory dispersion of (I) and (II) is expressed by a single-term Drude equation. [M] given below are calc. least max. [M]<sup>25</sup>. CHETPr-CO<sub>2</sub>H, m.p. 117—118°, leads to l-α-ethyl-n-valeric acid (III), b.p. 95°/8 mm., [M] -2.21° (cinchonidine salt), and Et d-α-ethyl-n-valerate, b.p. 108°/115 mm., [M] +7.33° (quinine salt of the corresponding acid), reduced to d-β-ethyl-n-amyl alcohol, b.p. 107°/100 mm., [M] +3.88°, and thence giving the bromide (IV), b.p. 109°/130 mm., [M] +1.04°. (II) leads to l-β-ethyl-n-amyl iodide, b.p. 132—133°/160 mm., [M] -0.66°, and l-γ-methyl-n-hexane, b.p. 92—93°. (IV) leads to β-ethylhexoic acid, b.p. 158—159°/79 mm., [M] -3.41°. CH<sub>2</sub>(CO<sub>2</sub>Et)<sub>2</sub> leads to d- (cinchonidine salt) and l-α-ethylhexoic acid, b.p. 120°/13 mm., [M] -23.5° (quinine salt; Et ester, b.p. 90°/28 mm., [M] -22.6°), and thence l-β-ethyl-n-hexyl alcohol, b.p. 110°/55 mm., [M] -7.72°, iodide, b.p.

60°/2 mm.,  $[M] = -24^\circ$ , and bromide, b.p. 110—111°/71 mm.,  $[M] = -19.4^\circ$ , d- $\beta$ -ethylheptonic acid,  $[M] = +7.41^\circ$ , and l- $\gamma$ -methyl-n-heptane, b.p. 115°. R. S. C.

Oxidation of drying oils and cognate substances. I. Oxidation of maleic anhydride compounds of  $\beta$ -elæostearic acid and its triglyceride. II. (A) Oxidation of maleic anhydride compound of  $\alpha$ -elæostearic acid. (B) Properties of maleic anhydride compounds of  $\alpha$ - and  $\beta$ -elæostearic acids. III. Effect of heat on oxidised  $\beta$ -elæostearin-maleic anhydride compound. R. S. MORRELL and W. R. DAVIS (J.S.C.I., 1936, 237—246T, 261—265T, 265—267T).—Controlled oxidation ( $H_2O_2$ -AcOH) of the maleic anhydride compounds of  $\alpha$ - and  $\beta$ -elæostearic acids yields the corresponding  $(OH)_2$ -derivatives, whilst hydrogenation ( $H_2$ -PtO<sub>2</sub>,  $H_2O$ ) affords compounds  $C_{18}H_{31}O_2 \cdot C_{18}H_{31}O_3$ , m.p. 74° and 63°, respectively. The effect of heat on the gels obtained by the gaseous oxidation of  $\beta$ -elæostearin-maleic anhydride compound in AcOH and CCl<sub>4</sub>, respectively, is described and a chemical interpretation is suggested. Previous findings (this vol., 313) are described in detail.

F. N. W.

Electrochemical investigations with  $\alpha$ -hydroxy-acids.—See this vol., 1347.

Reactions of pyruvic acid with thiolacetic acid and cysteine. E. FRIEDMANN and J. GIRŠAVIČIUS (Biochem. J., 1936, 30, 1886—1891).—When  $AcCO_2H$  (I) is mixed with  $SH \cdot CH_2 \cdot CO_2H$  (II), an exothermic reaction occurs and a white cryst. equimol. compound of (I) and (II) is formed which, on dissolution in  $H_2O$ , behaves like a mixture of free (I) and (II) both in its reactions with I and  $NaHSO_3$  and in the fact that (I) and (II) can be isolated therefrom. Cysteine in aq. or EtOH solution reacts slowly with (I) as shown polarimetrically and by iodometric titration. The compound is reasonably stable as judged from its behaviour to I and some colour reagents. P. W. C.

Preparation of homolævulic [ $\gamma$ -keto-n-hexoic] acid. E. FRIEDMANN (J. pr. Chem., 1936, [ii], 146, 159—162).— $COEt \cdot CH_2 \cdot CO_2Et$  (purified by way of the  $NaHSO_3$  compound), Na wire, and  $CH_2Br \cdot CO_2Et$  in  $Et_2O$  give a 66.5% yield of  $Et_2$  propionylsuccinate, b.p. 146—149°/10 mm., and thence by 5N- $H_2SO_4$  an 81% or by N-NaOH a 62% yield of  $\gamma$ -keto-n-hexoic acid, m.p. 40° (corr.), b.p. 140—148°/10 mm. (Et ester, b.p. 102—107°/12 mm.).

R. S. C.

Polynuclear heterocyclic rings. X. Determination of the rate of ring closure. M. STOLL and A. ROUVÉ (Helv. Chim. Acta, 1936, 19, 1079—1095; cf. A., 1935, 1251; this vol., 964).—Further examination of the behaviour of  $OH \cdot [CH_2]_{14} \cdot CO_2H$  shows that with 45% primary polymerisation the initial rate of reaction based on transformation of the initial products is greater at the start and slower at the end than the rate based on the functional groups. The corresponding velocity coeffs. differ widely from one another, that based on the initial acid declining first rapidly and then slowly to a limiting val., whilst that based on the functional groups falls very rapidly and finally becomes const. The rate of polymerisation to an acid concn.  $c = 11.7$  g. =

$45 \times 10^{-4}$  mol. per litre is  $>$ , and after this concn.  $<$ , the rate of monomeric lactone formation. This concn. determines the point at which the rates are equal, and must therefore be identical with the cyclisation const. The degree of cyclisation increases with the progress of the change. The ratio uni-: bi-mol. acid shows that the max. amount of ter- and quadri-mol. acid is  $> 8\%$  of the original material and that  $> 3\%$  of the latter is available for the production of substances of higher mol. wt. Reply is made to Salomon (this vol., 940). H. W.

Nature of the "activated form" of oxalic acid. E. SCHROER (Ber., 1936, 69, [B], 2037—2041).— $CHO \cdot CO_2H$  (I) is identified as the "activated form" of  $H_2C_2O_4$ , since a solution of the latter which has reacted with  $KMnO_4$  in absence of air until only a slight yellow colour persists gives a violet colour with fuchsin- $H_2SO_4$ . At the same stage of the reaction (I) can be detected with naphthoresorcinol or, more satisfactorily, with carbazole. Little  $H_2O_2$  is produced when solutions of (I) are shaken with air, but its formation becomes copious in presence of  $Mn^{++}$ . Little  $H_2O_2$  results in old solutions of (I) and none in those which are syrupy or have been boiled, probably on account of polymerisation of the acid. Identical amounts of (I) are found by the aldehyde and Ti reagents; these appear to decrease with increasing acidity of the solution. (I) reduces  $Hg^{II}$  salts in warm solution. The reaction of  $H_2C_2O_4$  and  $MnO_4^-$  in acid solution is given by the partial equations:  $4H_2C_2O_4 + 2MnO_4^- + 2H^+ \rightarrow 3CO_2 + Mn_2O_3 + 5H_2O$ ;  $H_2C_2O_4 + Mn_2O_3 \rightarrow (I) + 2MnO_2$ ;  $(I) + O_2 + H_2O \rightarrow H_2C_2O_4 + H_2O_2$ ;  $H_2O_2 + MnO_2 \rightarrow H_2O + MnO + O$ ;  $H_2C_2O_4 + MnO_2 \rightarrow H_2O + 2CO_2 + MnO$ .

$\alpha\alpha'$ -Dideuterosuccinic acid and its derivatives. II. Stereochemistry of the type  $CHDRR'$ . M. T. LEFFLER and R. ADAMS (J. Amer. Chem. Soc., 1936, 58, 1551—1555).—Reduction ( $D_2$ , PtO<sub>2</sub>, EtOAc) of (a) Et maleate and (b) Et fumarate gives apparently the same Et  $\alpha\alpha'$ -dideuterosuccinate, b.p. (a) 106.5—106.8°/16 mm., (b) 106—106.5°/16 mm., hydrolysed (very dil.  $HNO_3$ ) to the acid (I), m.p. 184—184.5° (anhydride, m.p. 119.3—119.6°). Fractional crystallisation of (I) failed to indicate more than one form. The brucine, m.p. 216—218° (decomp.), quinine (+ $H_2O$ ), m.p. (anhyd.) 198—201°, strychnine, m.p. 210° (softens at 190°), and cinchonine (II), m.p. 130—160°, salts of (I) have the same  $[\alpha]_D^{20}$  as the corresponding salts (same m.p.) of  $(-CH_2 \cdot CO_2H)_2$ . Quinine tetradeuterosuccinate has m.p. 198—201°. Different fractions of (II) showed no mutarotation. The above results indicate that  $CHDRR'$  shows symmetry. H. B.

Shellac. IX. Constitution of aleuritic acid. W. NAGEL and W. MERTENS (Ber., 1936, 69, [B], 2050—2052).—Confirmation of the structure  $OH \cdot [CH_2]_8 \cdot CH(OH) \cdot CH(OH) \cdot [CH_2]_7 \cdot CO_2H$  assigned to aleuritic acid (A., 1927, 445) is found in its conversion by successive treatment with  $COMe_2$ ,  $H_2SO_4$ ,  $KMnO_4$  (=4 O), and boiling dil. mineral acid into  $\kappa$ -dihydroxyhexadecanedicarboxylic acid, m.p. 125—127° (Mg salt). The corresponding Me<sub>2</sub> ester, m.p. 60—62.5°, yields a diacetate, b.p. 220—230°

(bath)/1 mm., and a  $\text{CMe}_2$  derivative, b.p.  $185^\circ/3$  mm. H. W.

$\alpha\beta$ -Dimethylascorbic acid and  $\alpha\beta$ -dimethyl- $\psi$ -ascorbic acid. F. MICHEEL and G. BISCHOFF (Annalen, 1936, 525, 66—73).— $\alpha\beta$ -Dimethyl- $\delta\epsilon$ -isopropylideneascorbic acid is greatly changed by dil. alkali without yielding derivatives of dimethyl- $\psi$ -ascorbic acid (I) (cf. A., 1935, 1106). Successive treatment of *l*-ascorbic acid with  $\text{CPh}_3\text{Cl}$  and  $\text{CH}_2\text{N}_2$  affords  $\epsilon$ -triphenylmethyl- $\alpha\beta$ -dimethylascorbic acid (II), m.p.  $159^\circ$ ,  $[\alpha]_D^{20} +34.2^\circ$  in  $\text{CHCl}_3$  (*p*-nitrobenzoyl derivative, m.p.  $154^\circ$ ,  $[\alpha]_D^{20} +24.3^\circ$  in  $\text{CHCl}_3$ ). Removal of the  $\text{CPh}_3$  residue from (II) followed by treatment with *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{COCl}$  leads to the known  $\delta\epsilon$ -di-*p*-nitrobenzoyl- $\alpha\beta$ -dimethylascorbic acid (III), showing that secondary change does not occur during the action of  $\text{CPh}_3\text{Cl}$ . (II) is isomerised by an excess of dil. alkali to a compound (IV), m.p.  $178^\circ$ ,  $[\alpha]_D^{20} +34.6^\circ$  in  $\text{CHCl}_3$ , which is not enantiomorphously related to (II). (IV) affords a non-cryst. *p*-nitrobenzoate. Removal of  $\text{CPh}_3$  from (IV) followed by treatment with *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{COCl}$  gives (III). Since the  $\epsilon$ - $\text{CPh}_3$  derivative of dimethylascorbic acid (V) does not become transformed into the similar derivative of (I), it follows that  $\epsilon$ -OH must be concerned with the isomerisation of (V) to (I), thus excluding the constitution assigned previously (*loc. cit.*) to (I). The mode of participation of  $\epsilon$ -OH in the formation of (I) is indicated by the observations that (I) does not react with  $\text{CPh}_3\text{Cl}$  and that *p*-nitrobenzoyldimethyl- $\psi$ -ascorbic acid is hydrolysed by  $\text{NaOH}$  and then loses

Me when treated with 0.1N-HCl at  $100^\circ$ , giving methyl- $\psi$ -ascorbic acid, which reduces Fehling's solution and affords a di-*p*-nitrobenzoylmethyl- $\psi$ -ascorbic acid. The most probable structure of (I) is therefore A or B, of which the former is the more likely since B requires a very ready hydrolysis of glucosidic Me.

H. W.

Kinetics of the reactions of polymeric aldehydes. II. Reaction of paraformaldehyde with cyanide. J. LOBERING and K. P. JUNG (Ber., 1936, 69, [B], 2147—2151).—Weighed amounts of paraformaldehyde (I) alone and in presence of varied amounts of KCN are shaken at  $30^\circ$ . Determinations of the quantities of dissolved (I) and of (I) utilised in the production of OH-nitrile after definite intervals of time show that the rate of reaction is governed by that of dissolution of (I), and that  $\text{CN}^-$  has no influence on the velocity of the change, which after an initial period is of the first order.

H. W.

Condensation of halogen-substituted aldehydes with nitro-paraffins. F. D. CHATTAWAY, J. G. N. DREWITT, and G. D. PARKES (J.C.S., 1936, 1294—1295; cf. A., 1935, 1224).—Equimol. amounts of chloral and  $\text{EtNO}_2$  in aq.  $\text{Na}_2\text{SO}_3$  and  $\text{Na}_2\text{CO}_3$  at  $40$ — $70^\circ$  give  $\delta\delta\delta$ -trichloro- $\beta$ -nitro- $\gamma$ -hydroxybutane, b.p.  $95^\circ/0.05$  mm.,  $115^\circ/2$  mm. (*Ac* derivative, b.p.  $98^\circ/$

$0.05$  mm.,  $125^\circ/2$  mm.). Butylchloral hydrate yields similarly  $\delta\delta\epsilon$ -trichloro- $\beta$ -nitro- $\gamma$ -hydroxyhexane, b.p.  $138^\circ/0.75$  mm. (*Ac* derivative, b.p.  $140^\circ/0.25$  mm.). Chloral and  $\text{CH}_2\text{Ph}\cdot\text{NO}_2$  afford  $\gamma\gamma\gamma$ -trichloro- $\alpha$ -nitro- $\beta$ -hydroxy- $\alpha$ -phenylpropane, m.p.  $109^\circ$  (*Ac*-derivative, m.p.  $98^\circ$ ). All products are inseparable mixtures of active forms.

R. F. P.

Condensation reactions of unsaturated aldehydes. V. Condensation reactions of crotonaldehyde under the influence of different condensing agents. K. BERNHAUER and K. IRRGANG [with K. ADLER, M. MATTAUCH, P. MULLER, and F. NEISER] (Annalen, 1936, 525, 43—65).—Immediately before each experiment the crotonaldehyde (I) is distilled in  $\text{CO}_2$  and condensation is then effected under  $\text{N}_2$ . The proportion of cyclic to open-chain aldehydes depends greatly on the *sec.* amine used. The best yields ( $>30\%$ ) of *o*-dihydrotolualdehyde (II) are obtained by the rapid action of  $\text{NH}_2\text{Et}$ ; prolonged action caused the disappearance of (II) owing to its condensation with (I) to products which resinify readily. With  $\text{NHMe}_2$  or piperidine (III) the yields of (II) are smaller and relatively best with pure (III) without addition of  $\text{AcOH}$  (cf. Kuhn *et al.*, this vol., 316). Dicrotonaldehyde,  $\text{CHO}\cdot\text{CH}_2\cdot\text{CHMe}\cdot\text{C}(\text{CHMe})\cdot\text{CHO}$ , is observed only under mild conditions of reaction, and is regarded as the precursor of (II). *p*-Dihydrotolualdehyde is formed mainly by slow action in aq. solution, and probably arises from the condensation of (I) with aldol; it is not produced in presence of dehydrating agents. Octatrienal (IV) appears only in limited amount, best in presence of anhyd. condensing agents or of  $\text{Na}_2\text{SO}_4$ . Pure (III) or  $\text{NH}_2\text{Et}$  is relatively inefficient, but better results are obtained with their acetates. Max. yields are secured with pure (III) and freshly distilled (I), whereby little (II) results; with the same catalyst and (I) distilled under  $\text{N}_2$  less (IV) and more (II) are produced. With this catalyst the addition of  $\text{AcOH}$  is disadvantageous. Non-cryst. acids are invariable by-products of the condensations.  $\text{NH}_2\text{Ph}$ ,  $\text{NHPhMe}$ ,  $\text{NPhMe}_2$ , and  $\text{C}_5\text{H}_5\text{N}$  have no condensing action and  $(\text{CH}_2\text{NH}_2)_2$  gives only a little (IV). Little condensation and, frequently, much resinification are caused by  $\text{NH}_2\text{Me}$ ,  $\text{NMe}_3$ , and  $\text{NMe}_4\text{OH}$ . Inorg. bases differ from *sec.* amines in that they never cause formation of cyclic aldehydes. Usually (III) is produced directly from (I), and then suffers partial fission to sorbaldehyde; fission is observed with alkali hydroxides and carbonates,  $\text{Ba}(\text{OH})_2$ , and aq. (III), but not with  $\text{Na}_2\text{HPO}_4$ , which therefore gives the highest yields of (IV). Dimeric (I) (identified as dimeric crotonic acid, m.p.  $64$ — $66^\circ$  or m.p.  $71^\circ$  when very rapidly heated; after re-solidification, m.p.  $78$ — $81^\circ$ , independent of the rate of heating) is produced. The position of  $\text{Ba}(\text{OH})_2$  is exceptional in that it causes formation of (II). Acid catalysts give the highest yields of condensation products,  $10\%\text{H}_2\text{SO}_4$  and  $7.5\%\text{HCl}$  behaving almost identically; resin formation is very small. Both cause the formation of very little (IV) and give mainly dimeric (I) and its trimeride, m.p.  $63^\circ$  (semicarbazone, m.p.  $213.5^\circ$ ; *p*-nitrophenylhydrazone, m.p.  $208.5^\circ$ ; phenylhydrazone, m.p.  $139$ — $141^\circ$ ), oxidised

to trimeric crotonic acid, m.p. 159.5° (dibromide, m.p. 151°); both are attributed to the intermediate formation of acetaldehyde.

Gradual addition of H<sub>2</sub>O to a mixture of (I), citral, and BaO followed by oxidation of the distilled product with Ag<sub>2</sub>O gives a cryst. acid, C<sub>13</sub>H<sub>20</sub>O<sub>2</sub>, m.p. 99°, probably cyclic in structure. H. W.

**Hydrolysis of  $\alpha$ , $\beta$ -dichloro- $\beta$ -methylpropane** producing isobutaldehyde. J. M. HERSH and R. E. NELSON (J. Amer. Chem. Soc., 1936, 58, 1631—1633).—CMc<sub>2</sub>Cl-CH<sub>2</sub>Cl, b.p. 38.6—39.2°/70 mm., 106.5°/760 mm., best prepared by low-temp. chlorination of Bu<sup>n</sup>Cl, is hydrolysed in the vapour phase at 350° by H<sub>2</sub>O (ratio 20:1) in presence of catalysts (activated Al<sub>2</sub>O<sub>3</sub> being most effective) to Pr<sup>n</sup>CHO (90—100% yield on product consumed). H. B.

**Refractometric studies in normal methyl ketones.** P. CEUTERICK (Bull. Soc. chim. Belg., 1936, 45, 545—564).—The mol. refractivity is determined of a series of  $\alpha$ -substituted Et acetoacetates (R=3—10 C), which are hydrolysed (10% NaOH) to the corresponding ketones. The mol. refractivities of the latter indicate that the contribution of CH<sub>2</sub> is 4.612 units at 15° and 4.630 at 30°, which shows that CO does not affect the val. for CH<sub>2</sub> (cf. A., 1933, 815). Assuming the val. for H, the vals. 4.675 and 4.665 are calc. for CO at 15° and 30°, respectively.

J. L. D.

**Colorimetric determination of acetone by the salicylaldehyde method.** A. RAVIN (J. Biol. Chem., 1936, 115, 511—518).—The method as described is capable of determining 0.0005 mg. of COMe<sub>2</sub> per c.c.

F. A. A.

**Addition of acetyl chloride to alkylacetylenes.** J. W. KROEGER, F. J. SOWA, and J. A. NIEUWLAND (J. Org. Chem., 1936, 1, 163—169; cf. this vol., 312).—Addition of AcCl to alkylacetylenes CR:CR' in presence of SnCl<sub>4</sub> gives mainly the chloroketones CRCl:CR'Ac (I) with some CRCl:CH:R' (II). In this way the following have been prepared: *cis*-, b.p. 97—99°/30 mm., and *trans*-, b.p. 89—91°/30 mm.,  $\delta$ -chloro- $\gamma$ -ethyl- $\Delta^2$ -hexen- $\beta$ -one, *cis*-, b.p. 117—118°/28 mm., and *trans*-, b.p. 112—113°/28 mm.,  $\delta$ -chloro- $\gamma$ -n-propyl- $\Delta^2$ -hepten- $\beta$ -one,  $\delta$ -chloro- $\gamma$ -n-butyl- $\Delta^2$ -octen- $\beta$ -one, b.p. 140—146°/28 mm.,  $\delta$ -chloro- $\gamma$ -n-amyl- $\Delta^2$ -nonen- $\beta$ -one, b.p. 115—121°/5 mm.,  $\delta$ -chloro- $\Delta^2$ -hexen- $\beta$ -one, b.p. 46—53°/10 mm., *cis*-, b.p. 62—63°/10 mm., and *trans*-, b.p. 54.5—55.5°/10 mm.,  $\delta$ -chloro- $\Delta^2$ -hepten- $\beta$ -one, *cis*-, b.p. 80°/10 mm., and *trans*-, b.p. 69°/10 mm.,  $\delta$ -chloro- $\Delta^2$ -octen- $\beta$ -one, *cis*-, b.p. 99°/10 mm., and *trans*-, b.p. 89°/10 mm.,  $\delta$ -chloro- $\Delta^2$ -nonen- $\beta$ -one,  $\gamma$ -chloro- $\Delta^2$ -hexene, b.p. 113.0—113.5°/748 mm.,  $\delta$ -chloro- $\Delta^2$ -octene, b.p. 157.5—159.5°/750 mm.,  $\epsilon$ -chloro- $\Delta^2$ -decene, b.p. 99—100°/28 mm.,  $\zeta$ -chloro- $\Delta^2$ -dodecene, b.p. 128—129°/28 mm.,  $\beta$ -chloro- $\Delta^2$ -butene, b.p. 57—59°/748 mm. (lit. 61—62°),  $\beta$ -chloro- $\Delta^2$ -hexene, b.p. 109.5—110.5°/735 mm.,  $\beta$ -chloro- $\Delta^2$ -heptene, b.p. 138—139°/748 mm. (lit. 71°/75 mm.). On keeping, the *cis*- and *trans*-isomerides are converted into an equilibrium mixture. With NaOAc-EtOH the *trans*-compounds give an immediate ppt. of NaCl, obtained only after several days from the *cis*-isomerides. The *trans*-isomeride is obtained on addition of HCl in presence of Cu<sub>2</sub>Cl<sub>2</sub> to the appropriate

acetylenic ketone. A mechanism for the formation of (I) and (II) is proposed involving the fission of AcCl into keten and HCl followed by addition of these products to the acetylene.

H. G. M.

**Dioximes. CXV.** G. PONZIO (Gazzetta, 1936, 66, 475—479).—The peroxide of the dioxime of diacetylglucose peroxide (A., 1925, i, 79) is reduced by NH<sub>2</sub>OH.HCl in C<sub>5</sub>H<sub>5</sub>N to dimethyl tetraketone tetra-oxime, m.p. 190° (decomp.) [complex Ni salt; (C<sub>5</sub>H<sub>5</sub>N)<sub>2</sub> salt, m.p. 170° (decomp.)]; Ac<sub>4</sub> derivative, m.p. 127° (decomp.); Bz<sub>4</sub> derivative, m.p. 209—210°. Similarly the peroxide of the dioxime of dibenzoylglucose peroxide yields diphenyl tetraketone tetra-oxime.

E. W. W.

**Optical rotatory dispersion in the carbohydrate group. VII. Glucal series.** T. L. HARRIS, R. W. HERBERT, E. L. HIRST, C. E. WOOD, and H. WOODWARD (J.C.S., 1936, 1403—1408; cf. this vol., 60).—Absorption spectra and rotatory dispersions are given for xylal diacetate, glucal 3:4:6-triacetate, lactal, lactal hexa-acetate, cellobial, and cellobial hexa-acetate. The data for xylal diacetate are expressed by a one-term Drude-Natanson equation; the other substances require two-term equations. A common low-frequency term, corresponding with an absorption band with  $\lambda$  2000—2200 Å., indicates dissymmetry of the ethylenic linking. In the xylal series the contributions of the two saturated asymmetric centres cancel out, leaving the full contribution of the ethylenic linking evident; the latter is, however, partly offset by the contribution of the three saturated asymmetric centres in the glucal series. The large difference in  $[\alpha]$  in these two series is thus explained. Other observations are in accord with expectation.

R. F. P.

**Use of micro-organisms in sugar analysis. II. Quantitative differentiation of fructose and mannose.** T. F. NICHOLSON (Biochem. J., 1936, 30, 1804—1806).—Continuing earlier work (A., 1933, 1037), a method is described for determination of mannose (I) which depends on the facts that *Monilia krusei* removes glucose (II), fructose (III), and (I) from solution whilst *Gaffkya tetragen* removes only (II) and (III). Combining the use of these organisms with the use of a strain of *Proteus vulgaris* which removes (II) but leaves (III) and (I), it was possible to analyse mixtures of (I), (II), and (III) and to recover added (III) and (I) from blood and urine filtrates.

P. W. C.

**Isomerisation of hydroxyaldehydes. VI. Saccharic transformation of monoses.** S. N. DANILOV and A. M. HACHOKIAN (Ber., 1936, 69, [B], 2130—2141).—The possibilities of the formation of saccharic acids from monoses are discussed in the light of the author's observations with OH-aldehydes (cf. A., 1934, 281). The prep. of gluconic acid (I), OH·CH<sub>2</sub>·[CH(OH)]<sub>3</sub>·CH<sub>2</sub>·CO<sub>2</sub>H, m.p. 145°,  $[\alpha]_D^{25} +4.99$  in H<sub>2</sub>O (Ba salt,  $[\alpha]_D^{25} +9.4$  in H<sub>2</sub>O; Ca salt (also +1H<sub>2</sub>O),  $[\alpha]_D^{25} +6.4$  in H<sub>2</sub>O; phenylhydrazide, m.p. 176°), by the action of PbO on mono- or di-halogenated glucose triacetates is described. (I) is converted by Ac<sub>2</sub>O and NaOAc at 70—80° and then at 96—100° into the Ac<sub>4</sub> derivative, m.p. 110°

(phenylhydrazide, m.p. 143°), and by Ag<sub>2</sub>O and MeI at 40° into *Me tetramethylglucodeonate* (II), m.p. 81.5°,  $[\alpha]_D^{25} + 84.2^\circ$  in H<sub>2</sub>O, hydrolysed by aq. Ba(OH)<sub>2</sub> to the corresponding acid, m.p. 92—94° [phenylhydrazide, m.p. (indef.), 112—114°]. Glucal, m.p. 60—61°,  $[\alpha]_D^{25} - 67.3^\circ$  in H<sub>2</sub>O (obtained by hydrolysis of the corresponding triacetate with NH<sub>3</sub>-EtOH), is transformed by repeated treatment with Ag<sub>2</sub>CO<sub>3</sub> and MeI at 40° into non-cryst. *trimethylglucal*,  $[\alpha]_D^{25} + 21.4^\circ$  in H<sub>2</sub>O, which with Cl<sub>2</sub> in CHCl<sub>3</sub> at 0° yields 1:2-dichloro-3:4:6-trimethylglucose,  $[\alpha]_D^{25} + 121.1^\circ$  in CHCl<sub>3</sub>, converted by moist Ag<sub>2</sub>CO<sub>3</sub> in CHCl<sub>3</sub> into 2-chloro-3:4:6-trimethylglucose; this with Pb(OH)<sub>2</sub> in H<sub>2</sub>O at 18–25° and finally at 80–90° affords *trimethylglucodeonic acid*, OMe·CH<sub>2</sub>·CH(OH)·[CH·OMe]<sub>2</sub>·CH<sub>2</sub>·CO<sub>2</sub>H (Ba salt; phenylhydrazide, m.p. 122—125°), completely methylated to (II). H. W.

**Osazones. II. Structure of "anhydro-osazones" and fission of osazones by bases.** O. DIELS, R. MEYER, and O. ONNEN (Annalen, 1936, 525, 94—118; cf. A., 1935, 1225).—Dehydration of osazones under the influence of traces of acid appears a general reaction accompanied by the loss of 1 H<sub>2</sub>O except in the case of maltose. Frequently the products are stable only as hydrates from which H<sub>2</sub>O cannot be removed without decomp.; the Ac derivatives, however, are anhyd. The previous method of formulation, based on the identity of anhydro-glucosazone (I) with the osazone of the 3:6-anhydro-glucose (II) of Fischer and Zach (A., 1912, i, 678) and Ohle (A., 1928, 871), cannot be maintained, since the pentosazones undergo similar change, and

the structure  $N \begin{smallmatrix} \diagup \\ \text{CH} \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \text{C} \end{smallmatrix} \begin{smallmatrix} \diagup \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \text{NHPh} \end{smallmatrix}$  is suggested by the conversion of anhydro-osazones by NH<sub>2</sub>OH, HCl in EtOH into 4-phenylhydrazono-5-keto-4-phenyl-4:5-dihydropyrazole or its homologues, the inability of N-alkylated osazones to undergo dehydration, and the impossibility of transforming anhydro-osazones into osones by conc. HCl, PhCHO, or *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO. The alternative constitution  $N \begin{smallmatrix} \diagup \\ \text{CH} \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \text{C} \end{smallmatrix} \begin{smallmatrix} \diagup \\ \text{NH} \end{smallmatrix} \begin{smallmatrix} \diagdown \\ \text{NHPh} \end{smallmatrix}$

is suggested by the general behaviour of 4-pyrazolones, and strongly supported by the observation that the products derived from *l*-arabinose and *d*-xylose are optical antipodes, thus indicating the disappearance of the asymmetry of . . . The formation of (II) is not a normal case of osazone production, and slight variations of Ohle's procedure yield a compound, C<sub>19</sub>H<sub>20</sub>O<sub>3</sub>N<sub>4</sub>, m.p. 187—188°, differing from (I) and of unexplained constitution. Osazones are not as sensitive to [OH<sup>-</sup>] as to [H<sup>+</sup>], but are almost universally decomposed by 1% KOH-EtOH into glyoxal-osazone (V) or the products of its dehydration and an OH-acid. The point of scission therefore lies between C<sub>(2)</sub> and C<sub>(3)</sub>. The change is complex and ill-defined.

(I) gives *Ac*, m.p. 170°, and *Bz*, m.p. 161°, compounds and a *COMe*<sub>2</sub> derivative, m.p. 167—168°, converted by boiling MeCN into an *isomeride*, m.p. 220°. The *Ac* derivatives of anhydro-*d*-galactose and anhydrolactose-phenylosazone have m.p. 177°

and 195—196°, respectively. Cellobiosazone is transformed by very dil., boiling H<sub>2</sub>SO<sub>4</sub>-EtOH into *anhydro-cellobiosephenylosazone*, C<sub>24</sub>H<sub>30</sub>O<sub>8</sub>N<sub>4</sub>·H<sub>2</sub>O, m.p. 245° (decomp.) after softening at 225° (*Ac* derivative, C<sub>36</sub>H<sub>42</sub>O<sub>14</sub>N<sub>4</sub>, m.p. 197—198° after softening at about 180°), which is remarkably stable towards alkali. The following *o*-tolylosazones are described: *anhydro-d-glucose*, m.p. 168—170° (*Ac* derivative, m.p. 149°); *lactose*, m.p. 145—155°; *anhydrolactose*, m.p. 223—225° (slight decomp.); *cellobiose*, m.p. 150—152° after softening at 145°; *anhydrocellobiose*, m.p. 223—225° (decomp.); *l-arabinose*, m.p. 122—123°; *anhydro-l-arabinose*, m.p. 187—188°; *d-xylose*, m.p. 118—120°; *anhydro-d-xylose*, m.p. 188—189°,  $[\alpha]_D^{25} - 57.0^\circ$  in C<sub>5</sub>H<sub>5</sub>N. The *p*-tolylosazones of *anhydroglucose*, *d-galactose* (V), and *anhydro-d-galactose* have m.p. 202°, 193°, and 212°, respectively. *Anhydro-l-arabinosephenylosazone*, m.p. 180—181°,  $[\alpha]_D^{25} + 35.2^\circ$  in MeOH, and *anhydro-d-xylosephenylosazone*, m.p. 179—180°,  $[\alpha]_D^{25} - 32.1^\circ$  in MeOH, are described. The *p*-tolylosazones of glucose and galactose are converted by NH<sub>2</sub>OH, HCl in PrOH-H<sub>2</sub>O into a substance, C<sub>17</sub>H<sub>16</sub>ON<sub>3</sub>, m.p. 196°. Treatment of (I) with boiling 1% KOH-EtOH slowly yields the compound, C<sub>18</sub>H<sub>18</sub>O<sub>2</sub>N<sub>4</sub>, m.p. 164°. *d*-Glucosazone (III) when similarly treated affords di- $\alpha$ -phenylazo-ethylene, m.p. 144° (decomp.), the three stereoisomeric forms of (IV), m.p. 220° (decomp.), 155°, and 187°, respectively, and an acid, (?) C<sub>3</sub>H<sub>6</sub>O<sub>4</sub>, isolated as the *brucine* salt, m.p. 188°. (IV) is also derived from the osazones of *d*-galactose, lactose, and maltose. *d*-Glucose-*o*-tolylosazone yields a compound (V), C<sub>16</sub>H<sub>16</sub>N<sub>4</sub>, m.p. 141°, also obtained from *glyoxal-o-tolylosazone*, m.p. 136°, and KOH-EtOH. *d*-Galactose-*o*-tolylosazone, m.p. 160—161°, is transformed into (V) and a substance, C<sub>20</sub>H<sub>24</sub>O<sub>4</sub>N<sub>4</sub>, m.p. 185°. *d*-Glucose-*p*-tolylosazone yields *glyoxal-p-tolylosazone*, m.p. 238°, not identical with the compound, C<sub>16</sub>H<sub>18</sub>N<sub>4</sub>, m.p. 238°, derived from (IV), which is transformed by boiling EtOH into a substance, m.p. 205°. Cellobiosazone affords a product, C<sub>17</sub>H<sub>24</sub>O<sub>8</sub>N<sub>2</sub>, m.p. 223° (decomp.), differing in this respect from all other sugars examined. (III) is slowly transformed by 35% NH<sub>2</sub>Me in MeOH at room temp. into a compound, C<sub>19</sub>H<sub>25</sub>O<sub>3</sub>N<sub>5</sub>, m.p. 198—199° [normal sulphate, m.p. 237—238° (decomp.)]. H. W.

**Crystalline isopropylidene-*d*-threose and simple preparation of *d*- and *l*-threose.** M. STEIGER and T. REICHSTEIN (Helv. Chim. Acta, 1936, 69, [B], 1016—1019).—

(I.)

Successive treatments of benzylidene-arabitol with Pb(OAc)<sub>4</sub> in AcOH and dil. AcOH give *d*-threose, best isolated as the *COMe*<sub>2</sub> derivative (I), m.p. 84°,  $[\alpha]_D^{25} - 15.27^\circ$  in COMe<sub>2</sub>. The identity of the sugar is established by its almost quant. oxidation to *l*-tartaric acid. H. W.

**Characterisation of sugarphosphoric acids and constitution of the pentosephosphoric acid from cozymase.** H. VON EULER, P. KARRER, and B. BECKER (Helv. Chim. Acta, 1936, 19, 1060—1062).—Synthetic glucose-6- and ribose-5-phosphoric acid from inosic acid do not give CH<sub>2</sub>O when oxidised by

$\text{HIO}_4$ , whereas under these conditions ribose-3-phosphoric acid from yeast-nucleic acid gives 0.61 mol. of  $\text{CH}_2\text{O}$ . The pentosephosphoric acid from highly purified cozymase does not yield  $\text{CH}_2\text{O}$ , showing that both pentose mols. are esterified by  $\text{H}_3\text{PO}_4$  at the primary OH. Cytidylic acid, although containing  $\text{PO}_4$  at 3, does not yield  $\text{CH}_2\text{O}$  in consequence of its glucosidification with cytosine. H. W.

**Synthesis of glycofuranosides.** E. PACSU and J. W. GREEN (J. Amer. Chem. Soc., 1936, 58, 1823—1824).—Galactose  $\text{Et}_2$  or dibenzyl mercaptal with  $\text{HgCl}_2$  and yellow  $\text{HgO}$  (to neutralise  $\text{HCl}$  formed) in  $\text{EtOH}$  at low temp. gives a good yield of  $\beta$ -ethylgalactofuranoside. H. B.

**Glucose 5-methyl ether.** L. VON VARGHA (Ber., 1936, 69, [B], 2098—2102).—Diisopropylidene-glucose 3-*p*-toluenesulphonate is hydrolysed by  $\text{AcOH}$  at  $50^\circ$  to 1:2-isopropylidene-glucosefuranose 3-*p*-toluenesulphonate,  $[\alpha]_D^{20} -11.6^\circ$  in  $\text{CHCl}_3$ , which with  $\text{BzCl}$  in  $\text{CHCl}_3$  gives 1:2-isopropylidene-glucosefuranose 6-benzoate 3-*p*-toluenesulphonate,  $[\alpha]_D^{20} -11.4^\circ$  in  $\text{CHCl}_3$ , whence the non-cryst. 5-methyl-1:2-isopropylidene-glucosefuranose 6-benzoate 3-*p*-toluenesulphonate,  $[\alpha]_D^{20} -27.1^\circ$  in  $\text{CHCl}_3$ . Alkaline hydrolysis of the latter gives a non-homogeneous product, transformed by  $\text{Ac}_2\text{O}$  in  $\text{C}_5\text{H}_5\text{N}$  into 5-methyl-1:2-isopropylidene-glucosefuranose 3:6-diacetate (I), m.p.  $87^\circ$ ,  $[\alpha]_D^{20} -15.2^\circ$  in  $\text{CHCl}_3$ . The probability that the removal of the  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_2$  is not accompanied by a Walden inversion and that (I) is a derivative of glucose is strengthened by the almost quant. conversion of 1:2-isopropylidene-glucose 3-*p*-toluenesulphonate into 1:2-isopropylidene-glucose, m.p.  $158^\circ$ , under precisely similar conditions. This view is further confirmed by the mild alkaline hydrolysis of (I) to homogeneous 5-methyl-1:2-isopropylidene-glucosefuranose (II), b.p.  $145^\circ/0.3\text{ mm.}$ ,  $[\alpha]_D^{20} -13.1^\circ$  in  $\text{CHCl}_3$ , transformed by  $\text{Ag}_2\text{O}$  and  $\text{MeI}$  into 3:5:6-trimethyl-1:2-isopropylidene-glucosefuranose, b.p.  $138\text{--}140^\circ/12\text{ mm.}$ ,  $[\alpha]_D^{20} -27.3^\circ$  in  $\text{MeOH}$ . Dil.  $\text{AcOH}$  at  $100^\circ$  transforms (II) into 5-methylglucose (III), which does not yield a well-defined osazone. Probably (III) is a mixture of several tautomeric forms. The presence of free  $\text{CHO}$  is established by the immediate reddening of fuchsin- $\text{H}_2\text{SO}_4$ , instantaneous reduction of  $\text{KMnO}_4$ , and rapid reduction of cold Fehling's solution. It has  $[\alpha] \pm 0^\circ$  in  $\text{H}_2\text{O}$  and is not mutarotatory; in  $\text{EtOH}$  it has  $[\alpha]_D^{20} -10.6^\circ$ , the low val. pointing to the absence of an O bridge. H. W.

**Active form of monosaccharides. I. Reactivity of triphenylmethylglucose.** A. V. STEPANOV and B. N. STEPANENKO (Ber., 1936, 69, [B], 2046—2049).—Addition of  $\text{HCN}$  to glucose occurs less readily in 88% than in 10%  $\text{MeOH}$  due to smaller degree of dissociation of  $\text{NH}_4\text{CN}$ . In 10%  $\text{MeOH}$  addition is rapid initially but the rate falls and then increases owing to hydrolysis of the nitrile. In 88% or 98%  $\text{MeOH}$  the increase is not observed. 6-Triphenylmethylglucose reacts more rapidly than glucose. The result is attributed to increased ease of rupture of the O bridge owing to the presence of the negative group.

**Possibility of identifying small amounts of galactose as mucic acid.** A. SALVATORI, G.

LAPPONI, and S. BAGLIONI (Atti R. Accad. Lincei, 1934, [vi], 20, 437—444; Chem. Zentr., 1935, ii, 3956).—A method is given for detecting and determining 25 mg. of galactose in 25 c.c. of liquid.

**Open-chain derivatives of *d*-mannose.** M. L. WOLFROM and L. W. GEORGES (J. Amer. Chem. Soc., 1936, 58, 1781—1782).—aldehydo-*d*-Mannosoxime hexa-acetate (I), m.p.  $91\text{--}92^\circ$  (lit.  $94^\circ$ ), is hydrolysed ( $\text{H}_2\text{C}_2\text{O}_4\cdot 2\text{H}_2\text{O}$  in  $\text{MeOH}$ ) to the penta-acetate (II), m.p.  $122\text{--}123^\circ$ ,  $[\alpha]_D^{20} +15^\circ$  in  $\text{CHCl}_3$ , which is acetylated to (I) and converted by  $\text{HNO}_2$  (method: A., 1934, 1092) into aldehydo-*d*-mannose penta-acetate (III), a syrup [semicarbazone (IV), m.p.  $177\text{--}178^\circ$  (decomp.), also obtained by acetylation ( $\text{Ac}_2\text{O}\text{-C}_5\text{H}_5\text{N}$  in the cold) of mannosesemicarbazone], (III) with  $\text{EtSH}$  and  $\text{ZnCl}_2$  gives the  $\text{Et}_2$  mercaptal (Piric, this vol., 593). (IV) and  $\text{HNO}_2$  also give (III), which is oxidized to (II). *d*-Mannose thus shows a marked tendency to react in the open-chain form (cf. Deulofeu *et al.*, A., 1934, 394). H. B.

**Iodometric determination of fructose.** S. STREPKOV (Ann. Chim. Analyt., 1936, [iii], 18, 231—232).—The solution containing fructose (I) is warmed at  $48.5\text{--}49^\circ$  with a standard  $\text{CuCO}_3$  reagent (II), filtered from reduced  $\text{Cu}_2\text{O}$ , and  $\text{Cu}$  in an aliquot part is determined iodometrically. (I) is determined from the decrease in titre of (II). J. S. A.

***d*-Diisopropylidenealtrose.** M. STEIGER and T. REICHSTEIN (Helv. Chim. Acta, 1936, 19, 1011—1016).—The conversion of *d*-ribose into crude altrose and of the latter into its benzylphenylhydrazone (I), m.p.  $151^\circ$  (corr.), is described. Treatment of (I) with  $\text{PhCHO}$  and  $\text{BzOH}$  in  $\text{H}_2\text{O}$  at  $100^\circ$  gives a non-cryst. altrose (II),  $[\alpha]_D^{20} +22^\circ$  in  $\text{H}_2\text{O}$ , whilst a methylated product (III) results when  $\text{MeOH}$  at  $60\text{--}65^\circ$  is substituted for  $\text{H}_2\text{O}$ . (II) is transformed by  $\text{COMe}_2\text{-CuSO}_4\text{-H}_2\text{SO}_4$  into *d*-diisopropylidenealtrose, m.p.  $89^\circ$ ,  $[\alpha]_D^{20} +28.27^\circ$  in  $\text{COMe}_2$ , which does not yield appreciable amounts of acid when oxidised with  $\text{KMnO}_4$ , and hence is probably A. (III) gives an anhydroisopropylidene-*d*-methylaltroside,  $\text{C}_{10}\text{H}_{16}\text{O}_6$ , m.p.  $132^\circ$  after softening at  $128^\circ$ ,  $[\alpha]_D^{20} -43.04^\circ$  in  $\text{COMe}_2$ . H. W.

**Mechanism of carbohydrate oxidation. XX. Preparation of oligosaccharide acetates containing dihydroxyacetone constituents.** L. C. KREIDER and W. L. EVANS (J. Amer. Chem. Soc., 1936, 58, 1661—1665).—Partly a more detailed account of work previously reviewed (A., 1935, 477). The following is new.  $\beta$ -Cellobiosido-, m.p.  $169^\circ$  (all m.p. are corr.),  $[\alpha]_D^{20} -27.1^\circ$  in  $\text{CHCl}_3$  (*p*-nitrophenylhydrazone, m.p.  $176^\circ$ ), and  $\beta$ -gentiobiosido-, m.p.  $172^\circ$ ,  $[\alpha]_D^{20} -25.9^\circ$  in  $\text{CHCl}_3$  (methyl alcoholate, m.p.  $110\text{--}112^\circ$ , resolidifying with m.p.  $171\text{--}172^\circ$ ; *p*-nitrophenylhydrazone, m.p.  $155^\circ$ ), -dihydroxyacetone octa-acetates are prepared (method: this vol., 827) from  $\text{OH}\cdot\text{CH}_2\text{-CO}\cdot\text{CH}_2\text{-OAc}$  and acetobromo-cellobiose and -gentiobiose, respectively. Attempted

deacetylation (mildest conditions) caused deep-seated changes. H. B.

**Action of liquid ammonia on cellobiose octa-acetate.** L. ZECHMEISTER and G. TÓTH [with I. PINCZÉSI] (Annalen, 1936, 525, 14—24).—Treatment of cellobiose octa-acetate with liquid  $\text{NH}_3$  followed by acid hydrolysis of the product gives cellobiose or its osazone in quant. yield, showing that the reaction remains at the disaccharide stage and that  $\text{C}_{12}$  and  $\text{C}_{13}$ , the non-reducing half of the biose mols., and the bridge O are not concerned with the position of N. The mixed product is difficult to manipulate after exhaustive acetylation, but it is thereby established that very little of it is formed by union of cellobiose residues. Better results are obtained by gentle acetylation affecting only the NH groups, whereby the more sparingly sol. *acetamidocellobiose* (I) ( $\text{R}=\text{R}'=\text{O}$ ), m.p.  $246^\circ$  (corr.) after softening at  $225^\circ$ ,  $[\alpha]_D^{20} -20.3^\circ$  in  $\text{H}_2\text{O}$ , is obtained. The position of  $\text{NHAc}$  follows from the formation of  $\text{NH}_4\text{Cl}$  when (I) is boiled with  $N\text{-HCl}$ , the very low I val. of (I), its slight reducing power towards Fehling's solution, and the non-formation of an osazone. Treatment of (I) with  $\text{Ac}_2\text{O}$  in  $\text{C}_5\text{H}_5\text{N}$  gives the corresponding *peracetate*, m.p.  $196^\circ$  (corr.) after softening at  $194^\circ$ ,  $[\alpha]_D^{20} -8.4^\circ$  in  $\text{CHCl}_3$ , hydrolysed by  $\text{NaOMe}$  to (I). The mother-liquors from (I) yield *diacetamidocellobiose* (II) ( $\text{R}=\text{NAc}$ , and  $\text{R}'=\text{O}$  or  $\text{R}'=\text{NAc}$  and  $\text{R}=\text{O}$ ),  $[\alpha]_D^{20} -20^\circ$  in  $\text{H}_2\text{O}$ , which has a very low I val., does not reduce Fehling's solution

until hydrolysed, does not yield an osazone, and gives  $\text{NH}_4\text{Cl}$  when boiled with  $N\text{-HCl}$ . (II) gives an  $\text{Ac}_9$  derivative, m.p.  $196^\circ$  (corr.),  $[\alpha]_D^{20} -3.3^\circ$  in  $\text{CHCl}_3$ . Treatment of cellobiose with  $\text{NH}_3$  and of the product with  $\text{Ac}_2\text{O}$  in  $\text{C}_5\text{H}_5\text{N}$  gives the *substance*,  $\text{C}_{10}\text{H}_{55}\text{O}_{16}\text{N}$ , m.p.  $225^\circ$  (corr.). H. W.

**Semicarbazone and oxime acetates of maltose and cellobiose.** *aldehydoCellobiose octa-acetate*. M. L. WOLFROM and S. SOLTZBERG (J. Amer. Chem. Soc., 1936, 58, 1783—1785).—*Maltosesemicarbazone*, m.p.  $213^\circ$  (decomp.), is acetylated ( $\text{Ac}_2\text{O}$ — $\text{C}_5\text{H}_5\text{N}$  at  $60$ — $65^\circ$  and then at room temp.) to the  $\beta$ -*octa-acetate* (I), m.p.  $209$ — $210^\circ$  (decomp.),  $[\alpha]_D^{20} +61^\circ$  in  $\text{CHCl}_3$ , which contains 7 OAc and 1 NAc (method: this vol., 592). Similar acetylation (at room temp.) of cellobiosesemicarbazone gives the  $\beta$ -*hepta-acetate* (II), m.p.  $207$ — $208^\circ$ ,  $[\alpha]_D^{27} -21^\circ$  in  $\text{CHCl}_3$ , further acetylated (at  $40^\circ$ ) to the  $\beta$ -*octa-acetate* (III), m.p.  $240$ — $241^\circ$  (decomp.),  $[\alpha]_D^{23} -26.5^\circ$  in  $\text{CHCl}_3$ , also containing 7 OAc and 1 NAc. Successive oximation and acetylation of cellobiose hepta-acetate affords  $\beta$ -*cellobioseoxime nona-acetate* (IV), m.p.  $195$ — $195.5^\circ$ ,  $[\alpha]_D^{27} -8.5^\circ$  in  $\text{CHCl}_3$ , which is not hydrolysed by  $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  in  $\text{MeOH}$ . (I)—(IV) all possess ring structures. The cellobioscantoxime octa-acetate of

Zemplén (A., 1926, 822) is probably impure (IV). Cellobioseoxime is acetylated in the cold to an amorphous nona-acetate (which when heated gives cellobionitrile octa-acetate), hydrolysed ( $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$  in  $\text{MeOH}$ ) to *aldehydocellobioseoxime octa-acetate* (V), m.p.  $154$ — $155^\circ$ ,  $[\alpha]_D^{20} +30^\circ$  in  $\text{CHCl}_3$ , which contains 8 OAc and is converted by  $\text{HNO}_3$  into the amorphous *aldehydocellobiose octa-acetate*,  $[\alpha]_D +17.7^\circ$  in  $\text{CHCl}_3$ . This reduces Fehling's solution and is oximated to (V). The behaviour of the above cellobiose derivatives on acetylation is the reverse of that of the corresponding glucose compounds (A., 1934, 1092).

H. B.

**Verbenalol, aglucone of verbenalin.** J. CHEYMOL (Compt. rend., 1936, 203, 543—545).—Emulsin hydrolyses verbenalin (I) to glucose and *verbenalol* (II),  $\text{C}_{11}\text{H}_{14}\text{O}_5$ , m.p.  $133^\circ$  from  $\text{Et}_2\text{O}$  or  $140.5^\circ$  from  $\text{AcOH}$ ,  $[\alpha]_D^{19} -29.07^\circ$  in  $\text{H}_2\text{O}$  (cf. A., 1908, i, 197; 1928, 1137), which contains a lactone ring and a strongly reducing group. The ultra-violet absorption spectra of (I) and (II) are different. (I) with 2.5%  $\text{H}_2\text{SO}_4$  gives glucose and an *l*-aglucone, which may be (II). J. L. D.

**Starch and the Schardinger dextrans.** K. FREUDENBERG and W. RAPP (Ber., 1936, 69, [B], 2041—2045).—Detailed instructions are given for the separation of potato starch into amylose,  $[\alpha]_{5780}^{20} +203 \pm 1^\circ$  (initial) in 51%  $\text{H}_2\text{SO}_4$ ,  $[\alpha]_{780}^{20} +164 \pm 1^\circ$  in  $N\text{-NaOH}$  (acetate,  $[\alpha]_D^{20} +172 \pm 2^\circ$  in  $\text{CHCl}_3$ ), and amylopectin,  $[\alpha]_{5780}^{20} 206 \pm 1^\circ$  in 51%  $\text{H}_2\text{SO}_4$ ,  $[\alpha]_{5780}^{20} +169 \pm 2^\circ$  in  $N\text{-NaOH}$ . Methylstarch is obtained by treating starch acetate suspended in  $\text{COMe}_2$  with  $\text{NaOH}$  and  $\text{Me}_2\text{SO}_4$  at  $20^\circ$  and then at  $50^\circ$ ; the processes of acetylation and methylation are repeated, giving a product with 38—39% OMe. Methylation of  $\alpha$ -dextrin (I) is effected by adding a solution of K in liquid  $\text{NH}_3$  to a solution of (I) in the same solvent at  $-50^\circ$ , removing the solvent, and treating the residue with excess of  $\text{MeI}$  in  $\text{Et}_2\text{O}$ , thus yielding *methyl- $\alpha$ -dextrin* (II),  $[\text{C}_6\text{H}_7\text{O}_2(\text{OMe})_3]_5$ , m.p.  $208$ — $210^\circ$ ,  $[\alpha]_D^{20} +162^\circ$  in  $\text{CHCl}_3$ .  $\beta$ -Dextrin is methylated with greater difficulty and ultimately yields a product (III), m.p. (indef.)  $190^\circ$ ,  $[\alpha]_D^{20} +151^\circ$  in  $\text{CHCl}_3$ , with 42.5% OMe (theory 45.5% OMe). Treatment of (II) with boiling 1%  $\text{HCl}$ — $\text{MeOH}$  affords trimethylmethylglucoside; no trace of pentamethylglucose can be isolated from it after treatment with  $\text{BzCl}$  in  $\text{C}_5\text{H}_5\text{N}$  at  $30^\circ$  and on hydrolysis it appears to give 2:3:6-trimethylglucose (IV) exclusively. During hydrolysis of (II) and (III) by 51%  $\text{H}_2\text{SO}_4$  at  $20^\circ$ ,  $[\alpha]$  rises initially and then sinks to the val. required by (IV). The course of hydrolysis appears the same for each product. The initial rise indicates the presence of a readily ruptured  $\beta$ -union which is not a cellobiose linking. Takadiastase at  $p_{\text{H}}$  4.5 hydrolyses (I) to homogeneous glucose.  $\gamma$ -Dextrin appears to be changed similarly but more complex results are given by  $\beta$ -dextrin. H. W.

**Determination of specific weights of cellulose solutions.** Specific weights of double compounds of cellulose derivatives with organic solvents.—See this vol., 1337.

**Simple enamines with tertiary nitrogen.** C. MANNICH and H. DAVIDSEN (Ber., 1936, 69, [B],

2106—2112).—Aldehydes and *sec.* amines in presence of anhyd.  $K_2CO_3$  readily yield diamines which when suitably heated lose 1 mol. of *sec.* amine with formation of enamines, which readily darken when preserved, are moderately stable towards  $H_2O$  and alkali, but readily hydrolysed by acids. They add 1 mol. of *sec.* base. They are readily hydrogenated, thus giving a method of converting aldehydes into the corresponding *tert.* amines or into primary or *sec.* amines if the basic component contains  $CH_2Ph$ . Condensation of ketones with *sec.* amines does not occur in presence of  $K_2CO_3$ , but can sometimes be effected if  $CaO$  is used at a somewhat higher temp.  $MeCHO$ , piperidine (I), and anhyd.  $K_2CO_3$  at  $> 5^\circ$  afford  $\alpha\alpha$ -dipiperidinoethane, b.p.  $58-60^\circ/0.3$  mm., transformed by distillation at higher pressure into (I) and 1-vinylpiperidine, which is hydrogenated to 1-ethylpiperidine. The following compounds are analogously obtained: 1- $\Delta^{\alpha}$ -propenylpiperidine, b.p.  $61-63^\circ/10$  mm., hydrogenated ( $PtO_2$  in cyclohexane) to 1-propylpiperidine; 1- $\Delta^{\alpha}$ -butenylpiperidine, b.p.  $70-71^\circ/10$  mm., whence 1-n-butylpiperidine, and  $\alpha\alpha$ -dipiperidino-n-butane; 1- $\beta$ -methyl- $\Delta^{\alpha}$ -propenylpiperidine, b.p.  $65-67^\circ/12$  mm., whence 1-isobutylpiperidine; 1- $\Delta^{\alpha}$ -heptenylpiperidine, b.p.  $129-130^\circ/10$  mm., whence 1-n-heptylpiperidine, b.p.  $121^\circ/13$  mm. (picrate, m.p.  $98^\circ$ ); diethyl- $\Delta^{\alpha}$ -heptenylamine, b.p.  $134-140^\circ/110$  mm., whence diethylheptylamine, b.p.  $198^\circ$  (aurichloride, m.p.  $48^\circ$ ); non-homogeneous phenylmethyl- $\Delta^{\alpha}$ -butenylamine (in poor yield), hydrogenated to  $NPhMeBu^{\alpha}$ ; styryldiethylamine, b.p.  $147-150^\circ/16$  mm.; 1-styrylpiperidine, b.p.  $174-175^\circ/15$  mm., m.p.  $29-30^\circ$ , hydrogenated to 1- $\beta$ -phenylethylpiperidine, b.p.  $138-139^\circ/14$  mm.;  $\alpha\alpha$ -dibenzylmethylamino- $\beta$ -phenylethane, an oil, whence benzylstyrylmethylamine, b.p.  $171-173^\circ/0.7$  mm., hydrogenated ( $PtO_2$  in EtOH at  $45^\circ$ ) to benzyl- $\beta$ -phenylethylmethylamine, b.p.  $135-136^\circ/0.6$  mm. (methiodide, m.p.  $182^\circ$ ), and ( $Pd-C$  in EtOH) to  $\beta$ -phenylethylmethylamine (hydrochloride, m.p.  $157-158^\circ$ ); dibenzylstyrylamine, m.p.  $120^\circ$ , hydrogenated ( $PtO_2$  or  $Pd-C$ ) to dibenzyl- $\beta$ -phenylethylamine (hydrobromide, m.p.  $213^\circ$ ) or  $PhMe$  and  $CH_2Ph \cdot CH_2 \cdot NH_2$ , respectively;  $\beta$ -piperidino- $\alpha$ -phenyl- $\Delta^{\alpha}$ -propene, b.p.  $157-161^\circ/13$  mm., hydrogenated to  $\beta$ -piperidino- $\alpha$ -phenylpropane, b.p.  $143-145^\circ/14$  mm. (hydrobromide, m.p.  $208^\circ$ ; methiodide, m.p.  $181^\circ$ ); 1- $\Delta^{\alpha}$ -cyclohexenylpiperidine, b.p.  $116-118^\circ/16$  mm., from the base, cyclohexanone, and  $CaO$  at  $100^\circ$  during 50 hr., whence 1-cyclohexylpiperidine, b.p.  $106-107^\circ/16$  mm. [methiodide (II), m.p.  $253^\circ$ ]. (II) is transformed by  $Ag_2O-H_2O$  followed by heating at  $200^\circ$  into cyclohexylmethyl- $\Delta^{\alpha}$ -pentenylamine, b.p.  $108-110^\circ/14$  mm., hydrogenated ( $PtO_2$  in EtOH) to cyclohexylmethylamine, b.p.  $113-114^\circ/14$  mm.

**Formation of enamines and alleneamines from -unsaturated aldehydes and secondary bases.** C. MANNICH, K. HANDKE, and K. ROTH (Ber., 1936, 69, [B], 2112—2123).— $\alpha\beta$ -Unsaturated aldehydes are readily resinified in presence of *sec.* amines, whereby the latter behave entirely as catalyst. If, however, the liberated  $H_2O$  is absorbed by much anhyd.  $K_2CO_3$  and the temp. is carefully regulated, additive compounds  $NR_2 \cdot CHR \cdot CH:CH \cdot NR_2$  result. The latter readily darken on exposure to air, and are

frequently so unstable that they cannot be distilled in vac. They are very readily hydrolysed. The location of the double linking is established by hydrogenation. When heated they are converted into doubly unsaturated monoamines of the allene type. Gradual addition of freshly distilled acetaldehyde in Et<sub>2</sub>O to 45%  $NHMe_2-H_2O$  in Et<sub>2</sub>O accompanied by introduction of anhyd.  $K_2CO_3$  in successive small amounts at  $-5^\circ$  to  $0^\circ$  affords  $\alpha\gamma$ -bisdimethylamino- $\Delta^{\alpha}$ -propene, b.p.  $52-54^\circ/13$  mm. (60% yield), reduced ( $PtO_2$  in cyclohexane) to  $\alpha\gamma$ -bisdimethylaminopropane, b.p.  $143-145^\circ$  (picrate, m.p.  $207^\circ$ ; platinichloride, m.p.  $247^\circ$ ). The following are obtained analogously:  $\alpha\gamma$ -dipiperidinopropene, b.p.  $150-152^\circ/12$  mm. when very rapidly distilled (slow distillation appears to yield polymeric piperidinoallene), hydrogenated ( $PtO_2$ ) to  $\alpha\gamma$ -dipiperidinopropane, b.p.  $135-137^\circ/12$  mm. [platinichloride, decomp.  $230-232^\circ$ ; picrate, m.p.  $217-219^\circ$  (decomp.)], and reduced by  $Na-Hg$  in 10% AcOH to  $\gamma$ -piperidinopropanol, b.p.  $102-104^\circ/12$  mm. (corresponding benzoate hydrochloride, m.p.  $186^\circ$ );  $\alpha\gamma$ -bisdimethylamino- $\Delta^{\alpha}$ -butene, b.p.  $64^\circ/17$  mm., thermally decomposed into  $\alpha$ -dimethylamino- $\gamma$ -methylallene and hydrogenated to  $NMe_2Bu^{\alpha}$ ,  $NMe_2 \cdot CH_2 \cdot CH_2 \cdot CHMe \cdot NMe_2$ , and  $NHMe_3$ ;  $\alpha\gamma$ -dipiperidino- $\Delta^{\beta}$ -butene (I), hydrogenated ( $PtO_2$  in MeOH) mainly to  $\alpha\gamma$ -dipiperidinobutane, b.p.  $159-160^\circ/18$  mm. (hydrobromide, m.p.  $272-275^\circ$ ), and reduced by  $Na-Hg$  to  $\gamma$ -piperidinobutanol (nitrobenzoate hydrochloride, m.p.  $176^\circ$ ); 1-piperidino- $\gamma$ -methylallene, b.p.  $98^\circ/15$  mm. (aurichloride, m.p.  $91^\circ$ ), from (II) at  $130-140^\circ/vac.$ , hydrogenated to  $\alpha$ -piperidinobutane, b.p.  $172^\circ$  (picrate, m.p.  $131^\circ$ );  $\alpha\gamma$ -dipiperidino- $\alpha$ -phenyl- $\Delta^{\beta}$ -propene, m.p.  $58^\circ$  after softening at  $55-56^\circ$ , whence  $\gamma$ -piperidino- $\alpha$ -phenylpropane and  $\gamma$ -piperidino- $\alpha$ -phenylallene which is too unstable to permit isolation as such, but is characterised as the picrate, m.p.  $164^\circ$ , and hydriodide, m.p.  $211-212^\circ$  (decomp.) after softening at  $206-207^\circ$ , both of which yield  $CHPh \cdot CH \cdot CHO$  when distilled with steam and the latter of which is hydrogenated ( $PtO_2$  in abs. EtOH) to  $\gamma$ -piperidino- $\alpha$ -phenylpropane, b.p.  $140^\circ/15$  mm. (hydrochloride, m.p.  $184-185^\circ$ ; hydriodide, m.p.  $138^\circ$ ; methiodide, m.p.  $134-135^\circ$ ), also obtained from  $C_5H_{10}N \cdot CH_2 \cdot C \cdot CPh$ ;  $\alpha$ -dimethylamino- $\gamma\gamma$ -dimethyl- $\Delta^{\beta\gamma}$ -octatriene, b.p.  $123-124^\circ/12$  mm., hydrolysed to citral and hydrogenated mainly to  $\alpha$ -dimethylamino- $\gamma\gamma$ -dimethyl- $\Delta^{\beta\gamma}$ -octadiene [methiodide (II), m.p.  $178-180^\circ$ , which yields  $NMe_3$  when hydrogenated], which passes by addition of  $H_2O$  into  $\alpha$ -dimethylamino- $\gamma\gamma$ -dimethyl- $\Delta^{\beta}$ -octen- $\gamma$ -ol, b.p.  $125^\circ/11$  mm. (hydrochloride, m.p.  $110-111^\circ$ ; methiodide, m.p.  $111-112^\circ$ );  $\beta$ -methyl- $\zeta$ -methylene- $\Delta^{\beta\gamma}$ -octadiene (myrcene), b.p.  $56-58^\circ/15$  mm., obtained from (II) and  $Ag_2O$ , oxidised by  $KMnO_4$  to  $COMe_3$ ,  $CH_2(CO_2H)_2$ ,  $AcOH$ , and  $HCO_2H$  and hydrogenated ( $PtO_2$ ) to  $\beta\gamma$ -dimethyl- $\Delta^{\beta}$ -octene and thence slowly to  $\beta\zeta$ -dimethyloctene;  $\alpha$ -dimethylamino- $\gamma\gamma$ -dimethyl- $\Delta^{\delta}$ -octene, b.p.  $99-100^\circ/16$  mm. [hydrochloride, m.p.  $167^\circ$ ; methiodide, m.p.  $220-222^\circ$ , degraded (Hofmann) to  $\beta\zeta$ -dimethyl- $\Delta^{\beta\gamma}$ -octadiene, b.p.  $160-161^\circ$ , identical with  $\beta$ -linalolene], transformed by addition of  $H_2O$  into a substance,  $C_{22}H_{42}ON$ , b.p.  $128-130^\circ/14$  mm. (hygroscopic hydrochloride, m.p.  $96^\circ$ ; methiodide, m.p.  $100-101^\circ$ ), and hydrogenated ( $PtO_2$  in abs. EtOH) to  $\alpha$ -dimethyl-

amino- $\gamma$ -dimethyloctane, b.p. 96°/15 mm. (hydrochloride, m.p. 186—187°; methiodide, m.p. 242°).

H. W.

**Photochemical deamination of amino-acids.**—See this vol., 1349.

**Preparation of methionine-free natural leucine.** S. W. FOX (Science, 1936, 84, 163).—Recrystallisation of the formylated  $\text{NH}_2$ -acid yields (50%) a S-free leucine without appreciable racemisation.

L. S. T.

**Structure of Wedekind's ketenium compounds.** L. L. MILLER and J. R. JOHNSON (J. Org. Chem., 1936, 1, 135—140).—Wedekind's ketenium compounds (A., 1922, i, 234), formed in small amounts from  $\text{CH}_3\text{R}\cdot\text{COCl}$  and  $\text{CHR}_2\cdot\text{COCl}$  and  $\text{NEt}_3$ , are shown by hydrolysis and by synthesis to be the diethylamides of the acids, formed from  $\text{NHEt}_2$  present as impurity in the  $\text{NEt}_3$  used. The chief product,  $\text{CMe}_2\text{CO}$  dimeride, of the reaction with  $\text{Pr}^i\text{COCl}$  is obtained in 60% yield when anhyd.  $\text{Et}_2\text{O}$  or ligroin (60—80°) is used as solvent. The following have been prepared: isobutyryl, b.p. 192—194°/740 mm., phenylchloroacet., m.p. 51—51.5°, b.p. 156—158°/4 mm., dichloroacet., b.p. 124—126°/19 mm., and bromoacet., b.p. 114—117°/9 mm., -diethylamide.

H. G. M.

**Carbamide series. XIII. Nitroalkyl-carbamides and -biurets.** T. L. DAVIS and N. D. CONSTAN (J. Amer. Chem. Soc., 1936, 58, 1800—1803; cf. A., 1933, 383).— $\text{NHR}\cdot\text{CO}\cdot\text{NH}_2\cdot\text{HNO}_3$  ( $\text{R} = \text{Et}, \text{Pr}^i, \text{Bu}^i$ , m.p. 70—71°,  $n$ -amyl, m.p. 75°) and conc.  $\text{H}_2\text{SO}_4$  at <15° give  $N$ -nitro- $N'$ -ethyl-, m.p. 133—134° (lit. 130—131°),  $N'$ - $n$ -propyl-, m.p. 96°,  $N'$ - $n$ -butyl- (I), m.p. 80—81°, and  $N'$ - $n$ -amyl- (II), m.p. 62°, -carbamide, respectively, whilst  $\text{NHMe}\cdot\text{CO}\cdot\text{NH}_2\cdot\text{HNO}_3$  affords  $\text{NO}_2\cdot\text{NMe}\cdot\text{CO}\cdot\text{NH}_2$  (I) and (II) with  $\text{NH}_2\text{Ph}$  in warm  $\text{H}_2\text{O}$  give  $N$ -phenyl- $N'$ - $n$ -butyl-, m.p. 129—130°, and  $N'$ - $n$ -amyl-, m.p. 92°, -carbamide, respectively (also prepared from  $\text{PhNCO}$  and  $\text{NH}_2\text{Alk}$ ); (I) and warm conc. aq.  $\text{NH}_3$  afford  $\text{NHBu}^i\cdot\text{CO}\cdot\text{NH}_2$ .  $\text{NN}$ -Dimethyl-, m.p. 103—104°, -diethyl-, m.p. 118°, and -di- $n$ -propyl-, m.p. 165°, -carbamide nitrates with conc.  $\text{H}_2\text{SO}_4$  yield the  $\text{NAlk}_2\cdot\text{NO}_2$ ;  $\text{CO}(\text{NHMe})_2$  and  $\text{CO}(\text{NHEt})_2$  could not be nitrated.  $\alpha$ -Methyl- and  $\alpha$ -dimethyl-biuret with  $\text{HNO}_3$  (d 1.42) and conc.  $\text{H}_2\text{SO}_4$  at <15° give the  $\alpha'$ - $\text{NO}_2$ -derivatives, m.p. 99—100° (decomp.) and 114—115° (decomp.) (III), respectively, which with aq.  $\text{NH}_3$  afford the original biuret. (III) and  $\text{NH}_2\text{Me}$ ,  $n$ -amylamine, and  $\text{NH}_2\text{Ph}$  in  $\text{H}_2\text{O}$  yield  $\alpha\alpha'$ -trimethyl-, m.p. 154°,  $\alpha\alpha'$ -dimethyl- $\alpha$ - $n$ -amyl-, m.p. 149°, and -phenyl- $\alpha\alpha'$ -dimethyl-, sublimes about 225°, -biuret, respectively; in these reactions (III) probably rearranges to  $\text{NMe}_2\cdot\text{CO}\cdot\text{NCO}$  which then reacts with the  $\text{NH}_2\text{R}$ .

H. B.

**Optical rotation of configuratively related azides.** P. A. LEVENE and A. ROTHEN [with M. KUNA] (J. Biol. Chem., 1936, 115, 415—428).—In the series,  $\text{CHMeR}\cdot[\text{CH}_2]_n\cdot\text{X}$ , the results are similar for compounds in which  $\text{X} = \text{N}_3$  or halogen only if  $n = 0$ .  $d$ -sec.-BuOH,  $[\alpha] +6.82^\circ$ , with cold  $\text{COMe}_2$ -HI gives  $l$ -sec.-butyl iodide, b.p. 111—118°,  $[\alpha] -13.1^\circ$ , and thence the azide, b.p. 85°/500 mm.,  $[\alpha] +16^\circ$ , and  $d$ -sec.-butylamine,  $[\alpha] +0.9^\circ$  (hydro-

chloride,  $[\alpha] -0.4^\circ$  in  $\text{H}_2\text{O}$ ).  $d$ -Octan- $\beta$ -ol,  $[\alpha] +9.6^\circ$ , gives  $l$ - $\beta$ -iodo-, b.p. 52°/1 mm.,  $[\alpha] -33.3^\circ$ ,  $d$ - $\beta$ -azido-, b.p. 68/9 mm.,  $[\alpha] +28^\circ$  (homogeneous),  $+27.4^\circ$  in heptane, and  $d$ - $\beta$ -amino- $n$ -octane, b.p. 48°/9 mm.,  $[\alpha] +4.19^\circ$  (hydrochloride,  $[\alpha] -3.89^\circ$  in  $\text{H}_2\text{O}$ ; platinichloride).  $d$ -CHMeEt $\cdot\text{CH}_2\cdot\text{OH}$ ,  $[\alpha] -4.4^\circ$ , affords  $d$ - $\alpha$ -iodo-, b.p. 145—146°,  $[\alpha] +4.18^\circ$ , max.  $[M] +11.1^\circ$ ,  $d$ - $\alpha$ -azido-, b.p. 72°/138 mm.,  $[\alpha] +7.61^\circ$ , max.  $[M] +11.6^\circ$ , and  $l$ - $\alpha$ -amino- $\beta$ -methyl- $n$ -butane (hydrochloride,  $[\alpha] -0.124^\circ$  in  $\text{H}_2\text{O}$ , max.  $[M] -0.21^\circ$  in  $\text{H}_2\text{O}$ ).  $d$ - $\beta$ -Methylhexyl iodide,  $[\alpha] +0.37^\circ$ , gives  $l$ - $\alpha$ -azido- $\beta$ -methyl- $n$ -hexane, b.p. 59—60°/15 mm.,  $[\alpha] -0.3^\circ$ .  $l$ - $\beta$ -Methylnonan- $\alpha$ -ol,  $[\alpha] -2.58^\circ$ , yields  $d$ - $\alpha$ -iodo-, b.p. 86°/4 mm.,  $[\alpha] +0.68^\circ$ , and  $l$ - $\alpha$ -azido- $\beta$ -methyl- $n$ -nonane, b.p. 98—102°/10 mm.,  $[\alpha] -0.4^\circ$ .  $l$ - $\gamma$ -Methyl- $n$ -pentan- $\alpha$ -ol,  $[\alpha] -3.2^\circ$ , gives  $l$ - $\alpha$ -iodo-, b.p. 54°/12 mm.,  $[\alpha] -7.61^\circ$ , and  $l$ - $\alpha$ -azido- $\gamma$ -methylpentane, b.p. 145—148°,  $[\alpha] -7.58^\circ$ , max.  $[M] -26.3^\circ$  in heptane.  $d$ - $\delta$ -Methylhexan- $\alpha$ -ol,  $[\alpha] +3.21^\circ$ , gives  $d$ - $\alpha$ -iodo-, b.p. 74—75°/13 mm.,  $[\alpha] +3.63^\circ$ , max.  $[M] +26.2^\circ$ , and  $d$ - $\alpha$ -azido- $\delta$ -methylhexane, b.p. 157°/418 mm.,  $[\alpha] +3.83^\circ$ , max.  $[M] +17.3^\circ$  in heptane.  $[\alpha]$  and  $[M]$  are  $[\alpha]^{25}$  and  $[M]^{25}$  (homogeneous) unless otherwise stated.

R. S. C.

**Synthesis and refractometric study of saturated  $\alpha$ -methylnitriles.** C. DE HOFFMANN and E. BARBIER (Bull. Soc. chim. Belg., 1936, 45, 565—583).—Et  $\alpha$ -cyanopropionate (Na derivative) in EtOH with alkyl bromides affords Et  $\alpha$ -cyano- $\alpha$ -alkylpropionates. The following are described: Et  $\alpha$ -cyano- $\alpha$ -ethyl-, b.p. 84—85°/12 mm., -propyl-, b.p. 96—97°/11 mm., -butyl-, b.p. 105—106°/10.5 mm., -amyl-, b.p. 118—119°/10.5 mm., -hexyl-, b.p. 132—133°/10.5 mm., -heptyl-, b.p. 143—144°/10.5 mm., -octyl-, b.p. 155—156°/10.5 mm., -nonyl-, b.p. 167—168°/11.5 mm., -decyl-, b.p. 180—181°/12 mm., and -dodecyl-propionate, b.p. 204—205°/10.5 mm. These are converted by hydrolysis (decarboxylation) into  $\alpha$ -methyl-, m.p. 126—128°, -ethyl-, m.p. 111.4°, -propyl-, m.p. 79.6°, -butyl-, m.p. 69.2°, -amyl-, m.p. 78.8°, -hexyl-, m.p. 80.8°, -heptyl-, m.p. 76.4°, -octyl-, m.p. 81.4°, -nonyl-, m.p. 85.4°, -decyl-, m.p. 91.2°, and -dodecyl-propionamide, m.p. 96.8°, which with  $\text{P}_2\text{O}_5$  afford the corresponding nitriles, b.p. 103.4°/753.1 mm., 125.2°/755.2 mm., 146.6°/750.5 mm., 164.8°/761.8 mm., 184.8°/761.8 mm., 85.4°/10 mm., 99.9°/10 mm., 115.4°/10 mm., 133.4°/12 mm., 146.3°/12 mm., and 170.6°/12 mm. Many physical properties of the nitriles are tabulated and the mol. refractivity for  $\text{CH}_2$  is calc. as 4.632 at 15° and 4.644 at 30°.

J. L. D.

**Behaviour of tautomeric substances towards diazomethane.** F. ARNDT (Rev. Fac. Sci. Univ. Istanbul, 1936, 1, 1—8).—A summary of previous work (cf. A., 1933, 146; 1934, 770; 1935, 334; this vol., 59).

H. G. M.

**Introduction of silicon into fats.** G. KLEIN and H. NIENBURG (Ber., 1936, 69, [B], 2066—2068).—Esters  $[\text{CO}_2\text{R}\cdot\text{CH}_2\cdot\text{CH}(\text{O}\cdot\text{COR})\cdot\text{CH}_2\cdot\text{O}]_n\text{Si}$  and  $[\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{O}]_n\text{Si}$  are obtained when a mono- or di-glyceride (4 mols.) is heated with  $\text{Si}(\text{OEt})_4$  at 150—160°. Orthosilicates of the following are described:  $\alpha$ -monostearin, m.p. 70°;  $\alpha\beta$ -distearin, m.p.

68°;  $\alpha$ -mono-olein, non-cryst.;  $\alpha$ -monobutylin, non-cryst.;  $\alpha\beta$ -dibutylin, non-cryst. H. W.

**Organic compounds of mercury. XIV. Reaction of hydroxyethylmercury bromide with diazomethane.** R. C. FREIDLIN, A. N. NESMEJANOV, and F. A. TOKAREVA (Ber., 1936, 69, [B], 2019—2021; cf. this vol., 1132).—The action of  $\text{CH}_2\text{N}_2$  on hydroxyethylmercury bromide (I) in cold  $\text{Et}_2\text{O}$  gives  $\text{N}_2$  and an unstable oil which evolves  $\text{C}_2\text{H}_4$  quantitatively when warmed and gives  $\text{CH}_2\text{Br}\cdot\text{HgBr}$  with small amounts of  $\text{Hg}$  and  $\text{CH}_2\text{O}$  (formed from  $\text{CH}_3\text{N}_3$ ). The experiments do not permit a decision between the structures  $\text{CH}_2\cdot\text{CH}_2\cdot\text{HgBr}\cdot\text{OH}$  and  $\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{HgBr}$  for (I) but the latter is preferred.  $\text{CH}_2\text{Br}\cdot\text{HgBr}$  and 2% aq.  $\text{NaOH}$  yield  $\text{Hg}$ ,  $\text{CH}_2\text{O}$ , and  $\text{Br}^-$ .  $\text{HgBr}_2$  is transformed by a large excess of  $\text{CH}_2\text{N}_2$  into *Hg dibromomethyl*, m.p. 42—43°.

H. W.

**Co-ordination compounds of platinum halides with unsaturated substances.** M. S. KHARASCH and T. A. ASHFORD (J. Amer. Chem. Soc., 1936, 58, 1733—1738).—Compounds  $(\text{R}\cdot\text{PtCl}_2)_2$ , where  $\text{R} = \text{cyclohexene}$  (I), dipentene, pinene,  $\text{C}_2\text{H}_4$ , isobutene,  $\text{CHPh}\cdot\text{CH}_2$ ,  $(\text{CHPh})_2$ , or *trans*- $\text{C}_2\text{H}_2\text{Cl}_2$ , and  $(\text{R}\cdot\text{PtBr}_2)_2$ , where  $\text{R} = (\text{I})$  or  $\text{CHPh}\cdot\text{CH}_2$ , have been prepared. The respective m.p. of the above compounds are 145—146°, 151—152°, 138—141°, 170—180°, 144—145°, 169—171°, 191—192°, 155—160°, 150—151°, 153—154°. Optical and solubility data are recorded. E. S. H.

**Reduction of aromatic compounds with hydrogen and a platinum oxide-platinum-black catalyst in presence of halogen acid.** J. H. BROWN, H. W. DURAND, and C. S. MARVEL (J. Amer. Chem. Soc., 1936, 58, 1594—1596).—Reduction (Adams) of  $\text{PhBr}$ ,  $\text{PhCl}$ ,  $p\text{-C}_6\text{H}_4\text{Cl}_2$ ,  $p\text{-C}_6\text{H}_4\text{Br}_2$ , and *o*-, *m*-, and *p*- $\text{C}_6\text{H}_4\text{MeBr}$  gives the cyclohexane and  $\text{HHal}$  (which activates the catalyst);  $\text{PhI}$ ,  $o\text{-C}_6\text{H}_4\text{Br}\cdot\text{CO}_2\text{H}$ ,  $1\text{-C}_{10}\text{H}_7\text{Cl}$ , and  $1\text{-C}_{10}\text{H}_7\text{Br}$  were unaffected.  $\text{C}_6\text{H}_5$ ,  $\text{PhMe}$ ,  $\text{C}_6\text{H}_4\text{Me}_2$ ,  $s\text{-C}_6\text{H}_3\text{Me}_3$ ,  $\text{PhEt}$ , cymene, and  $\text{Ph}_2$  are similarly reduced in presence of a little  $\text{HCl}$  or  $\text{HBr}$ ; anthracene gives octa- and tetradeca-hydroanthracene but phenanthrene and  $\text{C}_{10}\text{H}_8$  are unaffected. The following reductions are effected similarly:  $\text{PhOH}$  to cyclohexanol (occurs more slowly in absence of  $\text{HHal}$ ),  $\text{EtOBz}$  to  $\text{C}_6\text{H}_{11}\cdot\text{CO}_2\text{Et}$ ,  $\text{COPhMe}$  to ethylcyclohexane,  $\text{PhOMe}$  to cyclohexane, and  $\alpha$ - and  $\beta\text{-C}_{10}\text{H}_7\cdot\text{OH}$  to the 5:6:7:8- $\text{H}_4$ -derivatives. H. B.

**Decomposition of cyclohexyl bromide in presence of mercuric bromide and the formation of cyclohexene polymerides.** F. SWARTS (Bull. Acad. roy. Belg., 1936, [v], 22, 784—790).—cyclohexyl bromide (0.1 mol.) when heated for 580 hr. with  $\text{HgBr}_2$  gave 0.06 mol. of polymerised cyclohexene (I), but the use of  $\text{HgBr}$  led to no appreciable polymerisation under similar conditions, nor was (I) produced in appreciable yield in the absence of  $\text{Hg}$  salts.  $\text{Cu}$  retarded the reaction, which was not appreciably catalysed by  $\text{Pt}$ . Pure cyclohexene (I) under similar treatment polymerised slightly; hence it is suggested that polymerisation occurs only at the moment of formation of (I). Fractional distillation of the polymerised substance gave cyclohexylcyclo-

hexene and resinous substances. From one fraction, crystallisation from  $\text{Et}_2\text{O}$  gave a substance,  $\text{C}_n\text{H}_{2n}$ , mol. wt. 568, corresponding with about 7 polymerised (I) mols. Some depolymerisation occurred when the resinous material was redistilled. J. T. A.

$\beta$ -cyclopentyl- $\alpha$ -phenylethane,  $\beta$ -cyclopentyl- $\alpha$ -cyclohexylethane,  $\gamma$ -cyclopentyl- $\alpha$ -phenylpropane,  $\gamma$ -cyclopentyl- $\alpha$ -cyclohexylpropane, and their behaviour towards catalytic hydrogenation and dehydrogenation. J. I. DENISSENKO (Ber., 1936, 69, [B], 2183—2187).—Addition of cyclopentanone to  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{MgCl}$  in  $\text{Et}_2\text{O}$  gives 1- $\beta$ -phenylethylcyclopentan-1-ol, b.p. 140—141°/5 mm., converted by boiling conc. aq.  $\text{H}_2\text{C}_2\text{O}_4$  into  $\beta$ -cyclopentyl- $\alpha$ -phenylethane, b.p. 124—125°/10 mm., rapidly hydrogenated ( $\text{Pt-black}$  in abs.  $\text{EtOH}$ ) to  $\beta$ -cyclopentyl- $\alpha$ -phenylethane (I), b.p. 255—256°/752.5 mm. Passage of (I) with  $\text{H}_2$  over  $\text{Pt-C}$  at 230° yields  $\beta$ -cyclopentyl- $\alpha$ -cyclohexylethane, b.p. 251—252°/752.5 mm., almost completely dehydrogenated by  $\text{Pt-C}$  at 290° to (I). Similarly, 1- $\gamma$ -phenylpropylcyclopentan-1-ol, b.p. 136—138°/2.5 mm., is converted successively into  $\gamma$ -cyclopentyl- $\alpha$ -phenylpropane, b.p. 117—118°/3 mm., and  $\gamma$ -cyclopentyl- $\alpha$ -phenylpropane (II), b.p. 271—272.5°/743 mm. (II) is hydrogenated to  $\gamma$ -cyclopentyl- $\alpha$ -cyclohexylpropane, b.p. 268—270°/748.2°, which is dehydrogenated to (II). H. W.

**Properties of carotene and lycopene.** N. K. DE (Indian J. Med. Res., 1936, 23, 949—956).—Carotene (I) and lycopene (II) behaved similarly towards reagents and adsorbents, but (I) was more sol. and (II) was more readily adsorbed. The spectroscopic absorption in various solvents was determined, and a rough method for the determination of mixtures of (I) and (II), by observing the positions of the absorption max., was devised. NUTR. ABS. (m)

**Isomerisation of carotenes by chromatographic adsorption.** I.  $\psi$ - $\alpha$ -Carotene. A. E. GILLAM and M. S. EL RIDI (Biochem. J., 1936, 30, 1735—1742).— $\psi$ - $\alpha$ -Carotene (I), m.p. 166° (uncorr.), formed from  $\beta$ -carotene by repeated adsorption on  $\text{Al}_2\text{O}_3$  (this vol., 155), is spectroscopically identical with  $\alpha$ -carotene (II) but is optically inactive. (I) is isomeric with (II) but whilst (I) is converted into a pigment with absorption max. at longer  $\lambda$ , (II) yields (especially by adsorption on  $\text{MgO}$ ) a pigment (*neo-carotene*) with absorption max. at shorter  $\lambda$ . The isomerisation is probably due to rearrangement of double linkings or to geometrical isomerism. F. O. H.

**Chemistry of the algæ. II. Carotenoid pigments of Oscillatoria rubescens.** I. M. HEILBRON and B. LYTHGOE (J.C.S., 1936, 1376—1380; cf. this vol., 259).—The epiphasic pigments consist of  $\beta$ -carotene (I) and myxoxanthin (II),  $\text{C}_{40}\text{H}_{56}\text{O}$ , m.p. 168—169° (single absorption max. in  $\text{CS}_2$ ,  $\text{CHCl}_3$ , and ligroin) (*oxime*, m.p. 195—196°, absorption max. 463 m $\mu$  in  $\text{CHCl}_3$ ), which has vitamin-A activity and must therefore contain a  $\beta$ -ionone ring; on microhydrogenation it absorbs 11  $\text{H}_2$  and is thus monocyclic. With  $\text{Al}(\text{OPr}^i)_3$  it affords myxoxanthol, m.p. 169—172° (absorption max. 529, 494, 464 m $\mu$  in  $\text{CS}_2$ ). This is the absorption spectrum of  $\gamma$ -carotene (III)

and analogy with (III) indicates that (II) is (A) or (B). (A) is precluded because (II) has a single absorption max., thus resembling astacene (IV). The enolic

(A)  $R = CH_2 \cdot CH \cdot CMe_2$

(B)  $R = CH \cdot CHPr^s$

form of (IV) closely resembles (II), wherefore (B) is preferred. The single-banded spectra of pigments such as (II) and (IV) is due to the simultaneous conjugation of the  $\cdot CO$  with two ethylenic linkings. The hypophase pigments include lutein and *myxoxanthophyll*,  $C_{40}H_{54}O_7$ , m.p. 169–170° (absorption max. 518, 484.5, 454 m $\mu$  in  $CHCl_3$ ).

R. F. P.

**Reversibility of the Friedel-Crafts reaction. Hydrogenation.** L. L. ALEXANDER and R. C. FUSON (J. Amer. Chem. Soc., 1936, 58, 1745–1747; cf. this vol., 205).—Dibenzyl (I) is formed in 27–57% yield when tri- and tetra-arylethanes (or compounds, e.g.,  $CAr:CAr$ ,  $CHAr:CHAr$ ,  $CAr_2:CHAr$ , which, under the conditions used, can give rise to these) are treated with  $C_6H_6$ ,  $AlCl_3$  (large excess), and dry  $HCl$  at room temp. Thus, tolane,  $CPh_2:CHPh$ ,  $CHPh_2:CH_2Ph$ ,  $(CPh_2)_2$ ,  $(CHPh_2)_2$ , and  $\beta$ -phenyl- $\alpha$ -di-*p*-chlorophenylethylene (II), m.p. 116.5–117.5° [obtained by dehydration ( $AcOH$ –conc.  $H_2SO_4$ ) of  $\beta$ -phenyl- $\alpha$ -di-*p*-chlorophenylethyl alcohol, m.p. 116–117°, which is prepared from  $CH_2Ph \cdot MgCl$  and  $(p-C_6H_4Cl)_2CO$ ], all give (I).  $(CHPh_2)_2$  is formed from tolane, (II), or  $CPh_2:CHPh$  with  $C_6H_6$ ,  $AlCl_3$  (limited amount), and  $HCl$ ;  $(CHPh_2)_2$  and *p*-bromostilbene similarly afford  $CHPh_2:CH_2Ph$ . The following mechanism for (II) illustrates the general reaction:  $CHPh.C(C_6H_4Cl)_2 (+C_6H_6) \rightleftharpoons CHPh \cdot CH(C_6H_4Cl)_2 (+2C_6H_6) \rightleftharpoons CHPh_2:CHPh_2 (+C_6H_6) \rightleftharpoons CPh_2:CHPh (+H_2) \rightarrow CHPh_2:CH_2Ph (+C_6H_6) \rightleftharpoons CHPh:CHPh (+H_2) \rightarrow (I)$ . The production of (I) from  $C_6H_6$ ,  $AlCl_3$ , and various halogenoethanes, -ethylenes, and -acetylenes is thus explicable.

H. B.

**Principle of vinylogy and the effect of ortho-substituents on the reactivity of benzene derivatives.** A. H. BLATT (J. Org. Chem., 1936, 1, 154–158).—Zwecker's comparison (A., 1935, 1112) of the relative reactivities of unsubstituted and *o*-substituted  $C_6H_6$  derivatives,  $C_6H_4RX$  ( $R=H$ ,  $Me$ , etc.;  $X=CO_2H$ ,  $CH_2Cl$ , etc.), with those of  $HX$  and  $RX$  is shown to be a special case of the principle of vinylogy (cf. Chem. Rev., 1935, 16, 1).

H. G. M.

**Hydrolysis of halogenobenzenesulphonic acids with alkali.** C. M. SUTER and P. H. SCRUTCHFIELD (J. Org. Chem., 1936, 1, 189–193).— $K$  or  $Na$  salts of 1:3:5- $C_6H_3X(SO_3H)_3$  (I) ( $X=Cl$ ,  $Br$ ,  $I$ ), 1:2:4- $C_6H_3Cl(SO_3H)_3$ , 1:3- $C_6H_4I \cdot SO_3H$ , and 1:3- $C_6H_4(SO_3H)_2$  have been hydrolysed in a  $N_2$  atm. with 60% aq.  $KOH$  (130–160°, 0.25–3 hr.), and (I) ( $X=Cl$  and  $Br$ ) have been fused with  $KOH$  (200–310°, 1–3 hr.), and the amounts of  $Cl^-$  and  $SO_3^{2-}$  formed determined. The halogens are more easily hydrolysed than the  $SO_3H$ , which, in turn, are hydrolysed more slowly

after hydrolysis of the halogen than before. The ratio of the hydrolysis rates for the halogen and  $SO_3H$  is greater in 60% alkali than in fusion reactions.

H. G. M.

**Organic substances of high mol. wt. Polybenzyl and its derivatives. II. Synthesis of the polymeride and its viscosity in varying solvents. III. Polynitrobenzyl.** S. BEZZI (Gazzetta, 1936, 66, 491–497, 497–504; cf. A., 1935, 1067).—II. Polybenzyl,  $(C_6H_4 \cdot CH_2)_n$  or  $CH_2Ph \cdot [CH_2 \cdot C_6H_4]_n \cdot C_6H_4 \cdot CH_2Cl$ , obtained by autocondensation of  $CH_2PhCl$  ( $AlCl_3$ , alone or in  $PhNO_2$ ,  $CS_2$ , or light petroleum), is shown by its viscosity in  $C_6H_6$  and in  $PhNO_2$ , at varying concn. and temp., to consist of long-chain mols., and not of micelles.

III. Polybenzyl with  $HNO_3$  (*d* 1.38) yields an insol. product containing less N than is required by  $(C_7H_5 \cdot NO_2)_n$ .  $HNO_3$  (*d* 1.52) gives a mixture of sol. and insol.  $NO_2$ -derivatives with N in excess (disubstituted in the terminal rings?). Mol. wt. (cryoscopic) shows that polybenzyls in which the degree of polymerisation is 5 to 24 all give sol.  $NO_2$ -derivatives in which it is only 5.5–6.5. The sp. viscosity of the latter is  $>$  that of polybenzyls of the same mol. wt. This, and the abnormal viscosity of cellulose, is ascribed to the effect of the functional groups.

E. W. W.

**Magnetochemical investigation of organic substances. X. Attempted synthesis of carbon diradicals; existence of diradicals.** E. MÜLLER and W. BUNGE (Ber., 1936, 69, [B], 2164–2172).—Attempts to remove  $Cl$  completely from 4:4'-dichlorodiphenylmethyldiphenyl ether necessitate the use of  $Cu$  powder in boiling  $C_6H_6$ , whereby a radical coloration is not observed and the product is a yellow amorphous substance,  $C_{76}H_{56}O_2$ , m.p. indef. 140°, apparently a dimeride. It is stable towards boiling  $SO_2Cl_2$ , but suffers fission with  $K-Na$ , thus resembling  $Ph_2O$ . In  $C_6H_6$  at room temp. and at 74° it is completely diamagnetic, and shows no sign of radical content. 4:4'-Di(chlorodiphenylmethyl)- $\alpha\beta$ -diphenylethane (Wittig *et al.*, A., 1928, 642) is transformed by  $Cu$  powder in  $C_6H_6$  into the almost colourless compound  $C_{40}H_{32}$ , which gives a colourless solution in  $C_6H_6$  if heating has been avoided in its prep., but is dark red in the hot solution. At room temp. and at 74° in  $C_6H_6$  the diamagnetic val. of the colourless solid is observed; a paramagnetic deviation corresponding with  $>2\%$  of radical is excluded. Paramagnetic C diradicals are capable of existence only when there is no possibility of intermol. stabilisation, of passage into a valency-tautomeric quinonoid system, or of equilibration with formation of a polymeric compound.

H. W.

**$\omega\omega'$ -Tetraphenylpolyene hydrocarbons; valency tautomerism of unsaturated systems.** G. WITTIG and A. KLEIN (Ber., 1936, 69, [B], 2087–2097).—With hydrocarbons  $CPh_2 \cdot CH \cdot [CH:CH]_n \cdot CH: CPh_2$  ( $n=1, 2$ , or 3) union with 2 atoms of alkali metal, probably at the ends of the conjugated systems, occurs, but  $O_2$  is without effect even in the presence of  $PhCHO$ . Addition of  $Br$  appears to take place with avoidance of the  $CPh_2 \cdot CH$  groups. The tetraphenylpolyenes do not

therefore give stable diyl forms and do not pass into diradicals in presence of  $O_2$  or Br. Tetraphenyl-*p*-xylylene reacts with Na-K in dioxan and the product affords  $p$ - $C_6H_4(CHPh)_2$ , m.p. 170—171°, when treated with MeOH. Gradual addition of Me.  $\alpha\alpha'$ -dihydromuconate to LiPh in Et<sub>2</sub>O and decomp. of the product with H<sub>2</sub>O gives  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\gamma}$ -hexene- $\alpha\zeta$ -diol (I), m.p. 163.5—165°, converted by HCl-MeOH in dioxan into  $\alpha\alpha'$ -dimethyl- $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\gamma}$ -hexene, m.p. 209—210°, which with Na-K followed by MeOH in dioxan yields  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\gamma}$ -hexene, m.p. 124—125°. (I) and boiling AcOH containing HCl afford  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\gamma\gamma}$ -hexatriene (II), m.p. 202—204°, which is converted by Na powder in abs. dioxan followed by MeOH into  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\beta\beta}$ -hexadiene (III), m.p. 148—149°, oxidised by  $KMnO_4$  in  $COMe$ , to  $CHPh_2 \cdot CO_2H$  and  $OH \cdot CPh_2 \cdot CO_2H$ , but not  $COPh_2$ . With Li a similar slow change is observed, whereas with Na-K reaction is much more rapid and gives (III) after short change, but  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\gamma\gamma}$ -hexadiene, m.p. 118—121° (oxidised to  $CHPh_2 \cdot CH_2 \cdot CO_2H$ , m.p. 154°), when reaction is prolonged. Partial hydrogenation of (II) gives  $\alpha\alpha\zeta\zeta$ -tetraphenylhexane and unchanged (II). In  $CHCl_3$  (II) gives a dibromide, decomp. about 133°, but it does not react with I. (II) is unchanged when shaken in  $C_6H_6$  with  $O_2$  alone or in presence of  $PhCHO$  or when dry  $O_2$  is passed through its solution in boiling  $C_6H_6$ .  $\alpha\alpha\zeta\zeta$ -Tetradiphenyl- $\Delta^{\gamma}$ -hexene- $\alpha\zeta$ -diol, m.p. 238—239°, is converted by HCl in boiling AcOH into  $\alpha\alpha\zeta\zeta$ -tetradiphenyl- $\Delta^{\gamma\gamma}$ -hexatriene, m.p. 320—328° (slight decomp.), which is darker in colour and gives a more marked fluorescence than (II), but is equally indifferent towards  $O_2$ . ( $CH_2 \cdot CO_2H$ )<sub>2</sub>,  $PbO$ ,  $Ac_2O$ , and  $\beta$ -phenylcinnamaldehyde (IV) at 140—150° afford  $\alpha\alpha\theta\theta$ -tetraphenyl- $\Delta^{\gamma\gamma\gamma}$ -octatetraene, m.p. 198—199°, which in  $CHCl_3$  gives a very unstable tetrabromide; it is indifferent to the prolonged action of  $O_2$ .  $\alpha\alpha'$ -Dihydromuconic acid,  $PbO$ ,  $Ac_2O$ , and (IV) at 140—150° give  $\alpha\alpha\kappa\kappa$ -tetraphenyl- $\Delta^{\gamma\gamma\gamma}$ -decapentaene, m.p. 227—228°, which affords an unstable hexabromide and is indifferent to  $O_2$ . H. W.

#### $\alpha\delta$ -Diarylbutadienes and related compounds.

I.  $\alpha$ -Phenyl- $\delta$ -1-naphthylbutadiene. E. FRIEDMANN and W. E. VAN HEYNINGEN (J. pr. Chem., 1936, [ii], 146, 163—165).— $CHPh \cdot CH \cdot CHO$ ,  $\alpha$ - $C_{10}H_7 \cdot CO_2H$ ,  $Ac_2O$ , and  $PbO$  at 200—230° give 24.9% of  $\alpha$ -phenyl- $\delta$ -1-naphthylbutadiene, m.p. 109°, which fluoresces in ultra-violet light and has absorption max. at 2360, 2775—2855, and 3260—3370 Å.  $\alpha\delta$ -Diphenylbutadiene has absorption max. at 2420 and 3305—3140 Å. R. S. C.

Reaction of metal halides with acetylenic Grignard reagents. J. P. DANEHY and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 1609—1610).— $CPh \cdot C \cdot MgBr$  (1 mol.) and  $CuBr$ , (1 mol.) in  $Et_2O$  give 72% of  $(CPh \cdot C)_2$ .  $CBu^s \cdot C \cdot MgBr$  (I) and  $CuBr$ , at 25° similarly afford  $(CBu^s \cdot C)_2$ , (60%; 55% at -5°) and  $CBu^s \cdot C \cdot Br$  (7%; 14% at -5°), which are also formed using  $CuCl_2$  at 25° (35 and 5%, respectively) or -5° (30 and 7%, respectively), and from  $CBu^s \cdot C \cdot MgCl$  and  $CuBr_2$  (30 and 1%, respectively).  $FeCl_3$  acts similarly. (I) and  $AgBr$

give  $CBu^s \cdot C \cdot Ag$  (60%), thus affording evidence that the first stage in the reaction between a Grignard reagent and a metal halide (as above) is the formation of an organometallic compound which, if unstable, subsequently decomposes. H. B.

Lattice structure of condensed aromatic hydrocarbons and their molecular compounds with trinitrobenzene.—See this vol., 1327.

Structure and reactivity of the naphthalene nucleus. I. Orientation in the series of naphthalene and its derivatives. V. N. UFMZEV (Ber., 1936, 69, [B], 2188—2198).—The main properties of  $C_{10}H_8$  (difference between  $\alpha$ - and  $\beta$ -substituted derivatives; equivalence of the four  $\alpha$ - and of the four  $\beta$ -positions; greater reactivity of the

$\alpha$ -positions) are adequately expressed by assuming an equilibrium between the forms (I) and (II). The assumption of a displacement (I)  $\rightarrow$  (II) on entry of a substituent into the nucleus explains the preponderating formation of mono-substituted products under mild conditions, since further action occurs with greater difficulty owing to the induced benzenoid character of the second ring; substances with completely similar rings [ $Ph_2 \cdot C_6H_4(CO)_2C_6H_4$ ] usually readily afford derivatives, and only under particular conditions are mono-substituted compounds obtained. Displacement of the equilibrium (I)  $\rightarrow$  (II) endows one ring with a more aromatic, the other with an unsaturated, character; further sulphonation causes entry of  $SO_3H$  in different positions, but only in the aromatic and difficultly hydrogenated ring, thus explaining the non-production of 1 : 3- $C_{10}H_6(SO_3H)_2$ . Examples from the lit. show that hydrogenation is considerably facilitated in the unsaturated ring, whereas in the other ring it occurs with about the same difficulty as with  $C_6H_6$ . If the structure with non-equiv. rings is considered fundamental to mono-substituted derivatives of  $C_{10}H_8$  the entry of a second substituent into the same ring follows the usual rules of  $C_6H_4$  orientation. If it enters the other ring, it is under the influence of a substituent in an unsaturated side-chain, and is subject to the rules of Holleman and Ingold. The processes are illustrated by references to the lit. Contrary to the lit., sulphonation of  $\beta$ - $C_{10}H_7 \cdot NHOAc$  in the cold gives mainly 2 : 8- $NHAc \cdot C_{10}H_6 \cdot SO_3H$ . Orientation of naphthylamine-sulphonic acids is readily effected by diazotisation, replacement of  $N_2$  by  $SO_2H$  by  $SO_2$  in presence of  $Cu$  powder, oxidation of  $SO_2Na$  to  $SO_3Na$  by  $H_2O_2$ , and conversion of  $C_{10}H_6(SO_3H)_2$  into  $C_{10}H_6(SO_2Cl)_2$ . H. W.

cyclopentenotriphenylene. E. BERGMANN and O. BLUM-BERGMANN (J. Amer. Chem. Soc., 1936, 58, 1678—1681).— $\beta$ -9-Phenanthrylethyl alcohol, m.p. 92° [from  $Mg$  9-phenanthryl bromide and  $(CH_2)_2O$  (in  $Et_2O$ - $C_6H_6$ ) or  $CH_2Cl \cdot CH_2 \cdot OH + MgEtBr$  (reaction occurs when the  $Et_2O$  is distilled off)], with  $SOCl_2$  in  $C_6H_6$ - $NPhMe_2$  gives the chloride, m.p. 82—84°, the Grignard reagent (A) from which with cyclopentanone affords 1-( $\beta$ -9-phenanthrylethyl)cyclopentanol (I), m.p. 108—109°, and a little  $\alpha\delta$ -di-9-phenan-

thylbutane (II), m.p. 214—216°. (I) is dehydrated (KHSO<sub>4</sub> at 160—170°) to 1-(β-9-phenanthryl)-Δ<sup>1</sup>-cyclopentene, b.p. 206—207°/1.3 mm., m.p. 50—54.5°, converted by AlCl<sub>3</sub> in CS<sub>2</sub> at room temp. into tetrahydrocyclopentenotriphenylene, m.p. 105.5—107° (picrate, m.p. 161—162°), which is dehydrogenated (Se at 330—340°) to cyclopentenotriphenylene (III), m.p. 171—172.5° (picrate, m.p. 172—173°). (III)

differs from the hydrocarbon, C<sub>21</sub>H<sub>16</sub>, to which structure (III) was assigned by Elderfield and Jacobs (A., 1934, 1359). (I) and AcOH-conc. H<sub>2</sub>SO<sub>4</sub> do not give (III); the resultant product [from which a hydrocarbon, C<sub>21</sub>H<sub>20</sub>, m.p. 117—120° (probably a spiran), is isolable] is dehydrogenated (Se at 320—340°) to (probably) 7-methyl-1:2-benzopyrene, m.p. 157.5—159.5° (picrate, m.p. 153—155°), and 1:2:3:4-dibenzfluorene, m.p. 115—116° (picrate, m.p. 165—167°). 2-Methylcyclopentanone and (A) give (II) and a product which when dehydrated (KHSO<sub>4</sub> at 160—170°) affords a little 1-(β-9-phenanthrylethyl)-2-methyl-Δ<sup>1</sup>-cyclopentene, m.p. 73—75°; much 9-ethylphenanthrene, m.p. 62—64°, is formed during the reaction. H. B.

**cycloHexylamine and N-dimethylcyclohexylamine.** G. BREUER and J. SCHNITZER (Monatsh., 1936, 68, 301—312).—Treatment of cyclohexyldimethylamine in Et<sub>2</sub>O with the appropriate amount of conc. H<sub>2</sub>SO<sub>4</sub> gives cyclohexylamine sulphate (I), m.p. 338°, and H sulphate, m.p. 117—118°, respectively, also obtained from their components. cycloHexylamine (II) and MeI in Et<sub>2</sub>O afford cyclohexylamine hydriodide (III), m.p. 193—194°, and cyclohexyltrimethylammonium iodide, m.p. 263°. (II) and hexyl iodide at room temp. or in Et<sub>2</sub>O yield (III), whereas at 100° cyclohexylhexylammonium iodide, m.p. 246°, is produced; cyclohexylhexylamine (IV), b.p. 243—245°/750 mm. (corresponding phenylcarbamide, m.p. 109—110°), is described. In Et<sub>2</sub>O (IV) and conc. H<sub>2</sub>SO<sub>4</sub> give (I). (III) is also formed from (II) and I in Et<sub>2</sub>O; ill-defined dark oils are produced simultaneously. H. W.

**Benzoylation of αs-phenylethylcarbamide.** E. A. ABRAHAM (J.C.S., 1936, 1273—1274; cf. A., 1884, 1321).—The Bz, m.p. 121°, and p-NO<sub>2</sub>-C<sub>6</sub>H<sub>4</sub>-CO-, m.p. 175°, derivatives of NPhEt·CO·NH<sub>2</sub> (I) have been prepared from (I) in C<sub>2</sub>H<sub>5</sub>N and the respective acyl chloride at room temp. BzCl and (I) at 100° yield NBzPhEt, cyanuric acid, and HCl. F. R.

**Action of bases on organic halogen compounds. I. Reaction of aryl halides with potassium amide.** F. W. BERGSTROM, R. E. WRIGHT, C. CHANDLER, and W. A. GILKEY. II. Basic catalysis in the dehalogenation of the phenyl halides. R. E. WRIGHT and F. W. BERGSTROM (J. Org. Chem., 1936, 1, 170—178, 179—188).—I. PhX (X=Cl, Br, I, but not F) reacts rapidly with KNH<sub>2</sub> in NH<sub>3</sub> at -33° to give NH<sub>2</sub>Ph and some NHPH<sub>2</sub>, NPh<sub>3</sub>, and p-C<sub>6</sub>H<sub>4</sub>Ph·NH<sub>2</sub>, but only slowly or not at all in boiling Et<sub>2</sub>O or C<sub>6</sub>H<sub>6</sub>. The relative ease of replacement of X was determined by the

“competition” method and follows the sequence Br>I>Cl (F not replaced at 33°), also obtained for replacements involving the p-phenylenedihalides. p-C<sub>6</sub>H<sub>4</sub>MeCl gives p-C<sub>6</sub>H<sub>4</sub>Me·NH<sub>2</sub> and tarry products. A mixture of mono- and di-phenylamines is also obtained from PhBr and Ca(NH<sub>2</sub>)<sub>2</sub> or Ba(NH<sub>2</sub>)<sub>2</sub> in NH<sub>3</sub> at room temp.

II. KNH<sub>2</sub> or rather the NH<sub>2</sub><sup>-</sup> ion catalyses the following reactions in liquid NH<sub>3</sub> at -33°, which proceed slowly or not at all in the absence of catalyst (cf. A., 1924, i, 726; 1931, 1166): NHPH<sub>2</sub>K+PhX=NHPH<sub>2</sub>+KX; NHPH<sub>2</sub>K+PhX=p-C<sub>6</sub>H<sub>4</sub>Ph·NH<sub>2</sub>+KX; NPh<sub>2</sub>K+PhX=NPh<sub>2</sub>+KX (X=Cl, Br, I); CPh<sub>3</sub>K+PhCl=KCl+CPh<sub>3</sub>; and the reactions with K quinaldyl and PhCl to give 2-benzyl-, 2-benzhydryl-, and 2-triphenylmethyl-quinoline. The following reactions, however, in liquid NH<sub>3</sub> at -33° do not take place either alone or in presence of KNH<sub>2</sub>: PhCl+KOPh=KCl+Ph<sub>2</sub>O and PhBr+KCl=PhCl+KBr. CHPh<sub>2</sub>K reacts slowly with PhCl in NH<sub>3</sub> at -33° in the absence of KNH<sub>2</sub> to give CHPh<sub>2</sub> and CPh<sub>3</sub>, and catalyses the reaction between NPh<sub>2</sub>K and PhCl. In general, the strongest bases (in Brønsted's sense) react most readily with PhX, and only the very strongest (NH<sub>2</sub><sup>-</sup> and CHPh<sub>2</sub>) catalyse reactions between PhX and NHPH<sub>2</sub>, etc. H. G. M.

**Extensions of the Leuckart synthesis of amines.** A. W. INGERSOLL, J. H. BROWN, C. K. KIM, W. D. BEAUCHAMP, and G. JENNINGS (J. Amer. Chem. Soc., 1936, 58, 1808—1811).—Ketones, CORR', are heated with a mixture of HCO<sub>2</sub>NH<sub>4</sub> and HCO·NH<sub>2</sub> (used alone with H<sub>2</sub>O-sol. and more volatile ketones) at 175—185° (with continuous removal of H<sub>2</sub>O by distillation) and the resulting CHRR'·NH·CHO hydrolysed (conc. HCl) to the dl-amine (52—85% yield). The following are described: CHPhMe·NH<sub>2</sub>; p-C<sub>6</sub>H<sub>4</sub>Me·CHMe·NH<sub>2</sub>; p-C<sub>6</sub>H<sub>4</sub>Ph·CHMe·NH<sub>2</sub> (178—179°, 220—221°); CHMeBu<sup>o</sup>·NH<sub>2</sub> (98—99°, >250°); α-m-tolyl-, b.p. 204—205° (113—114°, 164—165°), α-p-chlorophenyl-, b.p. 105°/10 mm. (144—145°, 192—193°), α-p-bromophenyl-, b.p. 116°/10 mm. (150—151°, 213—214°), α-p-anisyl-, b.p. 126°/20 mm. (117—118, 160—161°), α-p-phenoxyphenyl- (113—114°, 180—181°), α-m-nitrophenyl- (156—157°, 223—224°), and α-2-naphthyl- (151—152°, 198—199°), -ethylamines; fenchylamine, b.p. 190—191° (131—133°, >250°). The m.p. quoted in parentheses are those of the Bz derivative and hydrochloride, respectively. A mixture of neobornyl- (70%) and d-bornylamine is obtained from d-camphor in presence of PhNO<sub>2</sub>. H. B.

**Amide condensations. II. Transformations of acetoacetylphenylamide.** G. V. TSCHELINCEV and B. M. DUBININ (Ber., 1936, 69, [B], 2023—2026; cf. this vol., 463).—The adaptability of CH<sub>3</sub>Ac·CO·NPh<sub>2</sub> (I) to syntheses of the CH<sub>2</sub>Ac·CO·Et type is illustrated. (I) is transformed by cold conc. H<sub>2</sub>SO<sub>4</sub> into 2-keto-1-phenyl-4-methyl-1:2-dihydroquinoline (II), m.p. 134—135°, in almost quant. yield. With NHPH<sub>2</sub>·NH<sub>2</sub> in Et<sub>2</sub>O at 0° (I) gives the corresponding phenylhydrazones, m.p. 171—172°, which passes in boiling xylene into phenylmethylpyrazolone. The successive actions of Na and EtI

in EtOH on (I) lead to  $\alpha$ -ethylacetoacetylphenylamide, m.p. 70—71°, transformed by conc.  $\text{H}_2\text{SO}_4$  into 2-keto-1-phenyl-4-methyl-3-ethyl-1:2-dihydroquinoline, m.p. 116—117°.  $\alpha$ -Benzylacetoacetylphenylamide, m.p. 108—109°, gives a non-cryst. product with conc.  $\text{H}_2\text{SO}_4$ . Diacetylacetylphenylamide, m.p. 123—124°, from  $(\text{HNaAc} \cdot \text{CO} \cdot \text{NPh}_2)$  and  $\text{AcCl}$  in  $\text{Et}_2\text{O}$ , is transformed by conc.  $\text{H}_2\text{SO}_4$  into (II). H. W.

***o*- and *p*-Nitrophenylhydroxylamine.** R. KUHN and F. WEYGAND (Ber., 1936, 69, [B], 1969—1974).—Addition of finely powdered  $\text{o-C}_6\text{H}_4(\text{NO}_2)_2$  to a solution of ascorbic acid (I) in aq.  $\text{Na}_2\text{CO}_3$  under  $\text{N}_2$  and extraction of the solution with EtOAc after acidification with AcOH gives *o*-nitrophenylhydroxylamine (II), m.p. 74°, which with dil. aq.  $\text{Na}_2\text{CO}_3$  gives a dark blue solution of the Na salt,  $\text{OH} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2 \cdot \text{Na}$ , and with conc. aq. NaOH an intensely reddish-brown solution of the  $\text{Na}_2$  salt,  $\text{ONa} \cdot \text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2 \cdot \text{Na}$ , thus explaining the colour reactions of  $\text{o-C}_6\text{H}_4(\text{NO}_2)_2$  with aldoses, ketoses, and polyhydric aromatic phenols. For the prep. of (II) it is preferable to start from  $\text{o-NO-C}_6\text{H}_4 \cdot \text{NO}_2$  (III), since reaction can then be effected in acid solution and less (I) is necessary. (II) can be determined by running its solution in 50% EtOH into standard  $\text{K}_2\text{Fe}(\text{CN})_6$  under  $\text{N}_2$  until the blue colour is permanent, (III) being thus produced. Hydrogenation ( $\text{PtO}_2$  in abs. EtOH) of (II) gives  $\text{o-C}_6\text{H}_4(\text{NH}_2)_2$ . Similarly, reduction of  $\text{p-C}_6\text{H}_4(\text{NO}_2)_2$  or  $\text{p-NO-C}_6\text{H}_4 \cdot \text{NO}_2$  affords *p*-nitrophenylhydroxylamine (IV), m.p. 107°, which in dil.  $\text{Na}_2\text{CO}_3$  gives a cherry-red solution of the Na salt and in dil. NaOH a brownish-yellow solution of the  $\text{Na}_2$  salt, which is sensitive to air owing to the catalytic effect of traces of metal, since the colour persists in presence of KCN. (II) is exceedingly unstable and when cryst. passes into a blackish viscous mass within a few hr., but can be preserved for some weeks in an evacuated tube at 0°. (IV) is considerably more stable. H. W.

**Fission of tertiary amines by nitrous acid.** R. WEGLER and W. FRANK (Ber., 1936, 69, [B], 2071—2077).—*N*-Methylbornylamine, b.p. 88°/15 mm.,  $\alpha^{17}$ —59.1° (improved prep.), is converted by  $\text{HNO}_2$  solely into the NO-derivative. Bornyl-dimethyl- or -diethyl-amine is largely converted into camphor and, under certain conditions, scarcely any *tert.* amine can be regenerated. The best method for the separation of *sec.* and *tert.* amine is secured by use of a large excess of  $\text{NaNO}_2$  in cold 15—20%  $\text{H}_2\text{SO}_4$ . Fission of *tert.* amines by  $\text{HNO}_2$  appears general, and takes place most rapidly in AcOH at 40—80° or, much more slowly, at room temp.  $\text{N}_2\text{O}_3$  in dil. AcOH can replace  $\text{NaNO}_2$  or, better,  $\text{N}_2\text{O}_3$  can be passed into the amine in AcOH, whereby the change takes place with marked evolution of heat. The smallest alkyl residue attached to N is removed as aldehyde or ketone. Cyclic residues appear somewhat more firmly attached than aliphatic residues of equal size, but  $\text{CH}_2\text{Ph}$  is removed at least as readily as Me, thus giving a parallel with von Braun's observation on the fission with BrCN. Reaction with *tert.* amines containing one or more readily eliminable groups is quant., giving NO-compounds and aldehydes or the corresponding acids in amount showing the

absence of appreciable secondary change. The course of the reaction is uncertain, but the aldehyde appears to be a primary product. The change  $\text{NR}_2\text{R}' + \text{HNO}_2 \rightarrow \text{NR}_2 \cdot \text{NO} + \text{R}'\text{OH}$  is unlikely, since  $\text{R}'\text{OH}$  ( $\text{CH}_2\text{Ph} \cdot \text{OH}$ ) is not oxidised by  $\text{HNO}_2$  alone or in presence of *tert.* amine or NO-compound. The following substances appear new: nitroso-benzylethylamine, an oil; -benzylmethylamine, b.p. 145°/18 mm.; -dibenzylamine, b.p. 140°/0.2 mm.; -cyclohexylethylamine, b.p. 140°/17 mm.; -ethyl-octylamine, b.p. 147°/15 mm. H. W.

**Reactions of 8-nitro- $\alpha$ -naphthylamine and its derivatives.** H. H. HODGSON and J. H. CROOK (J.C.S., 1936, 1338—1341).—4:8-Dinitroaceto- $\alpha$ -naphthalide, m.p. 231° (free amine, m.p. 193°), was the sole product of the action of  $\text{HNO}_3$  (*d* 1.5) on 8-nitroaceto- $\alpha$ -naphthalide. Monobromination of the latter in AcOH+NaOAc gave 4-bromo-8-nitroaceto- $\alpha$ -naphthalide, m.p. 202°, hydrolysed to the amine, m.p. 116°, converted (Sandmeyer) into 1-chloro-4-bromo-8-nitronaphthalene, m.p. 107.5°, whilst further bromination gave the 2:4- $\text{Br}_2$ -compound (I), m.p. 198°, sol. in aq. NaOH, hydrolysed to the amine (II), m.p. 150°, converted (Sandmeyer) into 1-chloro-2:4-dibromo-8-nitronaphthalene, m.p. 146°, reduced (West's method) to 8-chloro-5:7-dibromo- $\alpha$ -naphthylamine, m.p. 159° (picrate, m.p. 160°; Ac derivative, m.p. 227°). Attempts at direct monobromination of 8-nitro- $\alpha$ -naphthylamine resulted in mixtures, whilst dibromination gave (II), which readily gave a  $\text{Ac}_2$  compound, m.p. 190°, with excess of  $\text{Ac}_2\text{O}$ , and was reduced (West's method) to 2:4-dibromo-1:8-naphthylenediamine, m.p. 110—112°. Reduction of (I) with acid  $\text{SnCl}_2$ -AcOH or by West's method caused condensation to 7:9-dibromo-2-methylperimidine, m.p. 176—177°. F. R.

**Manufacture of aminotrifluoromethylarylsulphonic acids.**—See B., 1936, 974.

**2:7-Diaminofluorene.**—See this vol., 1352.

**Azo-dyes and their intermediate products.** XVIII. *cis*- and *trans*-forms of stilbene dyes. P. RUGGLI and F. LANG (Helv. Chim. Acta, 1936, 19, 996—1007).—Observations with dyes derived from *cis*-stilbene disprove the hypothesis that substantivity of dyes on cotton depends on their existence in long, thread-like mols. which become attached to the similar mols. of cellulose. The by-products of the action of alkali on  $\text{p-NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{CH}_2\text{Cl}$  are formed in minor quantity only and are non-homogeneous; a substance, m.p. 199°, containing 5 O is described. *pp'*-Dinitrotolan, obtained from the dibromide or, preferably, the dichloride of *trans-pp*-dinitrostilbene, is reduced (Ni in EtOAc-EtOH- $\text{H}_2\text{O}$ ) to *cis-pp'*-diaminostilbene (I), m.p. 121° [ $(\text{CHPh})_2$ , m.p. 104°;

$Ac_2$ , m.p.  $172^\circ$ , and  $Bz_2$ , m.p.  $253^\circ$ , derivatives; *trans-pp'*-dibenzamidostilbene, m.p.  $352^\circ$ ], which is unchanged by prolonged treatment with cold or short treatment with boiling  $N\text{-HCl}$ , but is isomerised by the boiling 10% acid to *trans-pp'*-diaminostilbene (II). Both substances are cautiously tetrazotised and coupled with 1:4- $NH_2\cdot C_{10}H_6\cdot SO_3H$  to *cis*- (III) and *trans*- (IV) -stilbene-red

$[CH\cdot C_6H_4\cdot N_2\cdot C_{10}H_5(OH)\cdot SO_3Na]_2$ , each of which is a substantive dye, although the existence of (III) as a thread mol. is theoretically excluded. Reductive fission of (III) and (IV) yields (I) and (II), respectively. Similar coupling of tetrazotised (I) and (II) with 1:4- $OH\cdot C_{10}H_6\cdot SO_3H$  yields *cis*- and *trans*-stilbene-violet  $[CH\cdot C_6H_4\cdot N_2\cdot C_{10}H_5(OH)\cdot SO_3Na]_2$ , each of which is a substantive dye. H. W.

**3:5-Fluoronitroanisole.** A. C. DE DEGIORGI (Anal. Asoc. Quím. Argentina, 1936, 24, 1—2).—3:5-Nitroaminoanisole in  $HCl$  with  $NaNO_2$ , and subsequently 40%  $BF_3$  yields 3-nitroanisole-5-diazonium borofluoride, decomp.  $150^\circ$  (darkens at  $140^\circ$ ), which loses  $BF_3$  on warming to give 3:5-fluoronitroanisole, m.p.  $85^\circ$ . F. R. G.

**Action of sodium methoxide and ammonia on 1:3:5-fluorodinitrobenzene and 3:5-fluoronitroanisole.** A. C. DE DEGIORGI (Anal. Asoc. Quím. Argentina, 1936, 24, 3—10).—The halogen in 1:3:5- $C_6H_3F(NO_2)_2$  (A., 1935, 1229) but not in the corresponding  $Cl$ -,  $Br$ -, and  $I$ -compounds, is replaced by the action of  $NaOMe$  or  $NH_3$  in  $EtOH$ . The  $F$  in 1:3:5- $OMe\cdot C_6H_3F\cdot NO_2$  (preceding abstract) is not replaced by  $NH_3$  in  $EtOH$  and is replaced less readily than the  $F$  in  $m\text{-}C_6H_4F\cdot NO_2$  by  $NaOMe$ . These results are discussed in relation to the views of De Crauw (A., 1931, 1283). F. R. G.

**Orientation of *p*-methoxydiphenyl in the Friedel-Crafts reaction.** L. F. FIESER and C. K. BRADSHAW (J. Amer. Chem. Soc., 1936, 58, 1738—1741).—In the Friedel-Crafts reaction, 4-methoxydiphenyl is substituted about 66% in position 4', the remainder in position 3. Solvents have little effect on the ratio.  $p\text{-}C_6H_4Ph\cdot OMe$ ,  $(CH_2\cdot CO)_2O$ , and  $AlCl_3$  in cold  $PhNO_2$  give 24.5% of  $\gamma$ -keto- $\gamma$ -*p*-4'-methoxydiphenylbutyric acid (I), m.p.  $200\text{--}201^\circ$  (slight darkening) (*Me* ester, m.p.  $99\text{--}110^\circ$ ), and 60% of  $\gamma$ -keto- $\gamma$ -4-methoxy-3-diphenylbutyric acid (II), m.p.  $155^\circ$  (*Me* ester, m.p.  $48\text{--}49^\circ$ ), readily separable owing to the sparing solubility of the  $Na$  salt of (I). Reduction (Clemmensen) of the crude *Me* esters of (I) and (II) affords  $\gamma$ -*p*-4'-methoxydiphenyl-, m.p.  $148\text{--}149^\circ$  (previous softening), and  $\gamma$ -4-methoxy-3-diphenyl-, m.p.  $109^\circ$ , -butyric acid, respectively; the latter could not be cyclised ( $H_2SO_4$ ; acid chloride; Bougault). Oxidation of (I) with  $KMnO_4$ -aq.  $KOH$  and of (II) with  $NaOBr$  gives 4-methoxydiphenyl-4'-m.p.  $248\text{--}249^\circ$  (*Me* ester, m.p.  $172\text{--}173^\circ$ ), and -3-, m.p.  $166\text{--}167^\circ$ , -carboxylic acid, respectively, demethylated (48%  $HBr$ ,  $AcOH$ ) to 4-hydroxydiphenyl-4'- (III), m.p.  $293\text{--}294^\circ$  (*Me* ester, m.p.  $224\text{--}225^\circ$ ), and -3-, m.p.  $212\text{--}213^\circ$  (*Me* ester, m.p.  $93\text{--}94^\circ$ ), -carboxylic acid, respectively. (III) is oxidised (aq.  $KMnO_4$ ) to  $p\text{-}C_6H_4(CO_2H)_2$ . (I) and 2.5%  $NaOCl$  at  $100^\circ$  (bath) afford 3-chloro-4-methoxydiphenyl-4'-carboxylic acid, m.p.  $275\text{--}276^\circ$  (*Me* ester, m.p.

$145\text{--}146^\circ$ ), also prepared by oxidation (alkaline  $KMnO_4$ ) of 3-chloro-4-methoxy-4'-acetyldiphenyl, m.p.  $109\text{--}110^\circ$  (from 3-chloro-4-methoxydiphenyl,  $AcCl$ , and  $AlCl_3$  in  $CS_2$ ). 3-Bromo-4-methoxydiphenyl-4'-carboxylic acid, m.p.  $270\text{--}271^\circ$  (*Me* ester, m.p.  $148\text{--}149^\circ$ ), and 3-bromo-4-methoxy-4'-acetyldiphenyl, m.p.  $97\text{--}98^\circ$ , are prepared by analogous methods.  $p\text{-}C_6H_4Ph\cdot OMe$ ,  $AcCl$ , and  $AlCl_3$  in  $CS_2$  (at b.p.),  $C_2H_5Cl_4$  (at  $0\text{--}20^\circ$ ), or  $PhNO_2$  (at  $0\text{--}20^\circ$ ) give 65—75% of 4-methoxy-4'- (IV), m.p.  $153\text{--}154^\circ$  and some -3- (V), m.p.  $62\text{--}63^\circ$ , -acetyldiphenyl. Rearrangement (Fries) of  $p\text{-}C_6H_4Ph\cdot OAc$  affords 4-hydroxy-4'-, m.p.  $206\text{--}207^\circ$ , and -3-, m.p.  $61\text{--}62^\circ$ , -acetyldiphenyl, which are methylated to (IV) and (V), respectively. H. B.

**Condensation of phenols with ethanolamine and formaldehyde.** H. A. BRUSON (J. Amer. Chem. Soc., 1936, 58, 1741—1744).— $NH_2\cdot CH_2\cdot CH_2\cdot OH$  (1 mol.) and 30%  $CH_2O$  (1 mol.) followed (after 1 hr.) by  $o\text{-}C_6H_4Ph\cdot OH$  (1 mol.) in  $EtOH$ , give after heating at  $100^\circ$  (bath) 38% of a hydroxyphenyl- $N$ - $\beta$ -hydroxyethylbenzylamine,  $OH\cdot C_6H_3Ph\cdot CH_2\cdot NH\cdot CH_2\cdot CH_2\cdot OH$ , m.p.  $116^\circ$ , also obtained by prolonged interaction of equimol. quantities of the reactants in  $MeOH$  at  $20\text{--}25^\circ$ .  $p\text{-}C_6H_4Ph\cdot OH$  similarly affords a compound, m.p.  $102^\circ$ , which may be  $(OH\cdot C_6H_3Ph\cdot CH_2)_2N\cdot CH_2\cdot CH_2\cdot OH$ , whilst *p*-cyclohexylphenol gives a compound, m.p.  $170\text{--}171^\circ$ , of (probably) similar constitution. 5-Chloro-2-hydroxydiphenyl, 2:4- $C_6H_3Cl_2\cdot OH$ , 3-nitro-*p*-cresol,  $p\text{-}C_6H_4Bu^t\cdot OH$ , *p*-tert.-amylphenol,  $p\text{-}NO_2\cdot C_6H_4\cdot OH$ , and  $p\text{-}OH\cdot C_6H_4\cdot COPh$  similarly yield (probably) 5-chloro-2-hydroxy-3-phenyl-, m.p.  $182\text{--}183^\circ$ , 3:5-dichloro-2-hydroxy-, m.p.  $199\text{--}200^\circ$ , 3-nitro-2-hydroxy-5-methyl-, m.p.  $205\text{--}206^\circ$ , 2-hydroxy-5-tert.-butyl-, m.p.  $127\text{--}128^\circ$ , 2-hydroxy-5-tert.-amyl-, m.p.  $114^\circ$ , 5-nitro-2-hydroxy-, m.p.  $196^\circ$ , and 2-hydroxy- $\gamma$ -benzoyl-, m.p.  $188\text{--}189^\circ$ , - $N$ - $\beta$ -hydroxyethylbenzylamine, respectively. These substances react further with  $CH_2O$  to form resins. Resinous products were obtained from  $PhOH$ , cresols, *o*- and  $p\text{-}C_6H_4Cl\cdot OH$ , and *o*-cyclohexyl-, *p*-benzyl-, and *p*- $\alpha\gamma\gamma$ -tetramethylbutylphenols;  $m\text{-}C_6H_4(OH)_2$  gives an amorphous solid. H. B.

**Oxidation of pyrocatechol by tyrosinase.**—See this vol., 1417.

**cycloHexyltrichloromethylcarbinol.** J. W. HOWARD and R. J. BROWN (J. Amer. Chem. Soc., 1936, 58, 1657).— $Mg$  cyclohexyl bromide added to chloral in  $Et_2O$  gives cyclohexyltrichloromethylcarbinol, b.p.  $119\text{--}121^\circ/15$  mm. (acetate, b.p.  $176^\circ/680$  mm.; propionate, b.p.  $188^\circ/681.6$  mm.; butyrate, b.p.  $183^\circ/682.6$  mm.; benzoate, b.p.  $210^\circ/683.3$  mm.), in approx. 30% yield. H. B.

**Substituted hydroxybenzyl alcohols.** B. DUNNING, jun., F. DUNNING, and E. E. REID (J. Amer. Chem. Soc., 1936, 58, 1565—1568).—2-Hydroxy-4-, m.p.  $103^\circ$ , and -6-, m.p.  $80^\circ$ , -methyl-, -5-ethyl-, m.p.  $83^\circ$ , and -5-propyl-, m.p.  $73^\circ$ , -benzyl alcohol are prepared by reduction (Adams) of the appropriate  $OH\cdot C_6H_4Alk\cdot CHO$  (prep.; Reimer-Tiemann), whilst 5-bromo-3-iodo-, m.p.  $86^\circ$ , and 3-chloro-5-bromo-, m.p.  $93^\circ$ , -2-hydroxy-, 6-bromo-3-hydroxy-, m.p.  $124^\circ$ , and 3-bromo-4-hydroxy-, m.p.  $128^\circ$ , -benzyl alcohol are obtained by direct halogenation. The relative

bactericidal (towards *S. aureus*), anaesthetic, and anti-spasmodic activities of the above and *o*-, *m*-, and *p*-OH-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub>-OH, and the 3:5-Cl<sub>2</sub>-, -Br<sub>2</sub>-, and -I<sub>2</sub>-, 5-Cl-, -Br-, and -I-, and 5-Me derivatives of (I) are determined; the bactericidal activity rises as the partition coefficient, solubility in olive oil/solubility in H<sub>2</sub>O, increases. H. B.

**Mechanism of asymmetric synthesis with reference to a new type.** J. KENYON and S. M. PARTRIDGE (J.C.S., 1936, 1313—1317).—(+)-*Methyl-αβ-dibromo-n-propylcarbinol*, b.p. 103°/13 mm.,  $\alpha_{\text{D}}^{25} +2.04^\circ$ ,  $\alpha_{\text{D}}^{15} +2.15^\circ$ ,  $\alpha_{\text{D}}^{10} +2.46^\circ$ ,  $\alpha_{\text{D}}^8 +4.90^\circ$  (l, 0.5), obtained from (–)- $\alpha\gamma$ -dimethylallyl alcohol and Br-CHCl<sub>3</sub>, is oxidised by CrO<sub>3</sub>-AcOH to (+)-*Me αβ-dibromo-n-propyl ketone*, b.p. 90°/13 mm.,  $\alpha_{\text{D}}^{25} +3.06^\circ$ ,  $\alpha_{\text{D}}^{15} +3.34^\circ$ ,  $\alpha_{\text{D}}^{10} +3.85^\circ$ ,  $\alpha_{\text{D}}^8 +8.25^\circ$  (l, 0.25), whilst (+)- $\alpha\gamma$ -dimethylallyl alcohol by similar treatment gives the dl-*dibromo-alcohol*, b.p. 112°/20 mm., oxidised to dl-*Me αβ-dibromo-n-propyl ketone*, b.p. 90°/13 mm. Further, the similarly constituted (+)- $\gamma$ -phenyl- $\alpha$ -methylallyl alcohol (I) with Br-CHCl<sub>3</sub> gives a mixture of two carbinols separated by fractional crystallisation into d- (II), m.p. 112—113°,  $[\alpha]_{\text{D}}^{25} +107.1^\circ$ ,  $[\alpha]_{\text{D}}^{15} +115.9^\circ$ ,  $[\alpha]_{\text{D}}^{10} +128.0^\circ$ ,  $[\alpha]_{\text{D}}^{8} +261.0^\circ$  in CHCl<sub>3</sub>, and l-*αβ-dibromo-β-phenylethylmethylcarbinol*, m.p. 87—88°,  $[\alpha]_{\text{D}}^{25} -97.8^\circ$ ,  $[\alpha]_{\text{D}}^{15} -115.4^\circ$ ,  $[\alpha]_{\text{D}}^{10} -119.7^\circ$ ,  $[\alpha]_{\text{D}}^{8} -224.0^\circ$  in CHCl<sub>3</sub>. The latter are oxidised without separation to (–)-*αβ-dibromo-β-phenylethyl Me ketone*, m.p. 127°,  $[\alpha]_{\text{D}}^{25} -10.15^\circ$  (l, 2; c, 2.7 in CHCl<sub>3</sub>). Oxidation of the (+)- and (–)-carbinols yields respectively (+)- and (–)-ketones, both m.p. 127°, possibly optically pure since the rotatory powers were of equal magnitude and opposite sign. Addition of Br to the (–) form of (I) gives a (–)-*αβ-dibromo-β-phenylethylmethylcarbinol*, m.p. 112—113°, the optical enantiomorph of (II), oxidised to the optically pure (–)-ketone. It is thought that asymmetric addition takes place when there is a difference in energy associated with the diastereoisomeric intermediate products, a conclusion supported by the fact that there is an unexpectedly wide variation in the rotatory powers of the ketones obtained by oxidation of the mixtures of dibromo-alcohols by bromination at different temp., the (–)- or (+)-ketone predominating according to whether the temp. is low or high. F. R.

**Asymmetric reaction.** Preparation of an alcohol or of its diastereoisomeride, exclusively, by reactions asymmetric or not. F. KAYSER (Ann. Chim., 1936, [xi], 6, 145—248; cf. A., 1924, i, 825).—Hydratropaldehyde with the theoretical quantity of MgPhBr in Et<sub>2</sub>O affords (α)-*αβ-diphenylpropyl alcohol* (I), b.p. 180—182°/17—18 mm. [*phenylcarbamate*, m.p. 116°; *chloride*, m.p. 140°; boiling AcCl containing NaOAc affords an Ac derivative of indefinite b.p. and some of the (β)-acetate]. Similarly, β-*phenylbutaldehyde*, b.p. 120°/35 mm. (prep. described), with MgPhBr affords (α)-*αβ-diphenylbutyl alcohol* (II), b.p. 183—184°/18 mm. [oxidised to ethyldeoxybenzoin (III); *phenylcarbamate*, m.p. 119°; *chloride*, m.p. 49°; Ac, b.p. indefinite, and Bz, b.p. 110°/20 mm., derivatives]; αβ-diphenylpropaldehyde affords (α)-*αβγ-triphenylpropyl alcohol* (IV), m.p. 92° (cf. A., 1933, 710) [oxidised to benzyldeoxybenzoin

(V); by heating with KHSO<sub>4</sub> a product, m.p. 63°, is obtained identical with that from the (β)-diastereoisomeride; *phenylcarbamate*, m.p. 125°; *chloride*, decomp. when heated; Ac derivative, m.p. 70°]. (I), (II), and (III) are obtained free from the (β)-diastereoisomerides. Methyldeoxybenzoin (VI), (III), and (V) are not reduced by H<sub>2</sub>-Pt, -Ni, or -Pd, but with MgBu<sup>o</sup>Cl, a small amount of *sec.* alcohol, (VIII) (below), and γδ $\epsilon$ -*triphenyl-ββ-dimethylpentan-γ-ol*, m.p. 117°, respectively, are formed. Deoxybenzoin with MeI, EtBr, and CH<sub>2</sub>PhBr in warm EtOH containing NaOEt affords (VI), (III), and (V), respectively. (VI) with Na-Hg in EtOH or Na in hot EtOH affords (β)-*αβ-diphenylpropyl alcohol* (VII), m.p. 48° [oxidised to (VI); *phenylcarbamate*, m.p. 122°; the *chloride* is identical with that from (I); Ac derivative, m.p. 104°], and a compound, (C<sub>10</sub>H<sub>10</sub>O)<sub>n</sub>, m.p. 266°. Similarly (III) and (V) afford (β)-*αβ-diphenylbutyl alcohol* (VIII), m.p. 82° [oxidised to (III); *phenylcarbamate*, m.p. 124°; *chloride*, m.p. 78°; Ac derivative, m.p. 53°], and (β)-*αβγ-triphenylpropyl alcohol* (IX), m.p. 87° [oxidised to (V); dehydrated (KHSO<sub>4</sub>) to a substance, m.p. 63°; *phenylcarbamate*, m.p. 121.5°; *chloride*, m.p. 90°; Ac derivative, m.p. 90°], respectively. The asymmetric synthesis of one diastereoisomeride exclusively is explained by postulating a sp. influence (leading to distortion) of one alkyl (R) on the position in space occupied by CO with respect to R and R', thereby providing a favoured position for attack by the incoming R'' (from MgR''X). *trans*-Stilbene oxide (X) with MgEtBr affords (VIII) whereas the *cis*-isomeride (XI) gives (II) in poor yield. (X) with CH<sub>2</sub>Ph-MgCl gives (IX), whereas (XI) affords (IV). (X) with MgMeI gives a mixture of *di-αβ-diphenylpropyl ether*, m.p. 138°, a *polymeride* (?), m.p. 282°, of *diphenylpropyl alcohol*, and a *substance*, m.p. 56°; (XI) with MgMeI affords only stilbene. (X) with MgMeBr gives stilbene and (I), as does (XI). Methylstilbene oxide (A., 1932, 394) with H<sub>2</sub>-Ni in EtOH at 35—40° affords (VII). Benzylstilbene with BzO<sub>2</sub>H affords *benzylstilbene oxide*, m.p. 65—66°, reduced (Ni-H<sub>2</sub>) to (IX). In neither case is there any evidence of the presence of the α-diastereoisomeride, nor of the rupture of both C-O linkings of the oxido-compound.

J. L. D.

**Addition of alkyl halides to the ethylenic linking.** F. STRAUS and W. THIEL [and, in part, G. SZYSZKA] (Annalen, 1936, 525, 151—182).—OMe-CH<sub>2</sub>Cl (I) and OMe-CHPhCl (II) add on to unsaturated compounds alone or, better, in presence of HgCl<sub>2</sub> or, best, ZnCl<sub>2</sub>, SnCl<sub>4</sub>, or SbCl<sub>5</sub>, to give compounds >CCl-C-CHR-OMe (R=H or Ph), the Cl becoming attached to the most heavily substituted C. In the one case examined the bromide gave twice the yield given by the chloride. Reaction with dienes may be by 1:2- or 1:4-addition or both. The case of reaction is *cyclopentadiene* (III) > Δ<sup>1:3</sup>-*cyclohexadiene* (IV) > CMe<sub>2</sub>CH<sub>2</sub>, CMe<sub>2</sub>CHMe > butadiene (V) > mono-unsaturated alicyclic compounds. Yields are usually 70%. The course of reaction is not always certain. Solutions of the alkoxy-halides obtained from the acetal or aldehyde and HCl-MeOH can sometimes be used. *p*-OMe-C<sub>6</sub>H<sub>4</sub>-CH<sub>2</sub>Cl (VI), but not CH<sub>2</sub>PhCl, condenses. (CH<sub>2</sub>Br)<sub>2</sub>O readily condenses by both Br, (CH<sub>2</sub>Cl)<sub>2</sub>O less readily by both Cl. This

is held to support direct addition of alkyl halides to C in such compounds as  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$ . (I) and (V) give  $\alpha$ -chloro- $\epsilon$ -methoxy- $\epsilon$ -phenyl- $\Delta^5$ -pentene, b.p. 126—127°/12 mm. (dibromide, b.p. 150°/0.4 mm.), oxidised by  $\text{KMnO}_4\text{-COMe}_2$  to  $\text{OMe-CHPh-CH}_2\text{-CO}_2\text{H}$ , m.p. 101—102°, and  $\text{CH}_2\text{Cl}\cdot\text{CO}_2\text{H}$ . (II) and (V) give (1)  $\gamma$ -chloro- $\epsilon$ -methoxy- $\Delta^5$ , b.p. 35°/10 mm., 148°/756 mm., and  $\alpha$ -chloro- $\epsilon$ -methoxy- $\Delta^5$ -pentene, b.p. 56°/10 mm., 168°/758 mm.  $\text{OMe-CHPhBr}$  and (V) give  $\alpha$ -bromo- $\epsilon$ -methoxy- $\epsilon$ -phenyl- $\Delta^5$ -pentene, b.p. 92°/0.1 mm., and (VI) gives  $\alpha$ -chloro- $\epsilon$ -methoxy- $\epsilon$ -anisyl- $\Delta^5$ -pentene, b.p. 104°/0.1 mm. (13%). (II) and (IV) yield 1-chloro-2- or 4- $\alpha$ -methoxybenzyl- $\Delta^5$ -cyclohexene, b.p. 112°/0.1 mm., and the 2- or 4- $\alpha$ -methoxy-ethyl, b.p. 81°/10 mm., and -p-anisyl, b.p. 128—129°/0.02 mm., derivatives are also obtained.  $\text{CPh}_3\text{Cl}$  and (IV) afford  $\text{CHPh}_3$  and 1-chloro-2-triphenylmethyl- $\Delta^5$ -cyclohexene, b.p. 103°/2 mm. (II) and (III) give a 1-chloro-2- or -3- $\alpha$ -methoxybenzylcyclopentene, b.p. 99—100°/0.1 mm. (I) and  $\text{CMe}_2\cdot\text{CH}_2$  give *Me*  $\gamma$ -chloroisooamyl ether, b.p. 81—81.5°/120 mm., 136°/751 mm. (60% with 10% of  $\text{Bu}^n\text{Cl}$ ), readily hydrolysed by acid or alkali to  $\gamma$ -methoxy-tert.-amyl alcohol, b.p. 51—52°/15 mm., 144°/764 mm. (p-nitrobenzoate, m.p. 72—74°).  $\text{CMe}_2\cdot\text{CHMe}$  with (II) gives  $\gamma$ -chloro- $\alpha$ -phenyl- $\beta$ -methyl-tert.-amyl *Me* ether, b.p. 133—135°/16 mm., and with (I) *Me*  $\gamma$ -chloro- $\beta$ -methyl-tert.-amyl ether, b.p. 46—46.5°/14 mm., 153°/761 mm., converted by 5%  $\text{Na}_2\text{CO}_3$  into  $\delta$ -methoxy- $\beta$ - $\gamma$ -dimethylbutan- $\beta$ -ol, b.p. 159°/750 mm., 58—59°/15 mm., and some  $\alpha$ -methoxy- $\beta$ - $\gamma$ -dimethyl- $\Delta^5$ -butene, b.p. 28.5°/15 mm., 115°/750 mm. (II) and  $\text{CHPh}\cdot\text{CH}_2$  give  $\alpha$ -chloro- $\gamma$ -methoxy- $\alpha$ - $\gamma$ - or - $\alpha$ - $\beta$ -diphenylpropane, b.p. 122.5°/0.1 mm. (II) and cyclohexene give 2- $\alpha$ -methoxybenzylcyclohexyl chloride, b.p. 96°/0.2 mm., oxidised to an acid,  $\text{C}_{12}\text{H}_{14}\text{O}_2$ , m.p. 123.2° (*Me* ester, m.p. 26.5—27°, b.p. 144°/16 mm.), and a little  $\text{BzOH}$ ; (I) affords similarly 2- $\alpha$ -methoxy-ethylcyclohexyl chloride (45%), b.p. 89—91°/20 mm., 192°/763 mm. (II) and  $\Delta^2$ -dihydronaphthalene give 2-chloro-3- $\alpha$ -methoxybenzyl-1 : 2 : 3 : 4-tetrahydronaphthalene, which, however, decomposes into  $\text{C}_{10}\text{H}_8$ ,  $\text{HCl}$ , and  $\text{CH}_2\text{Ph}\cdot\text{OMe}$ , with some formation also of  $\text{CH}_2\text{PhCl}$ ;  $\Delta^1$ -dihydronaphthalene reacts more violently, but no pure product was isolated. R. S. C.

**Phenyl  $\beta$ -hydroxy- $\beta$ -diphenylvinyl sulphone.**—See this vol., 1327.

**Cyclitols. III. Configuration of the active inositols.** T. POSTERNAK (Helv. Chim. Acta, 1936, 19, 1007—1010; cf. A., 1932, 1127).—Regulated oxidation by  $\text{KMnO}_4$  of *l*-inositol (I) (prep. from revertex through quebrachitol described) gives mucic

and *d*-saccharic acid the isolation of which establishes the configurations (I) and (II) for (I) and *d*-inositol, respectively. *d*-Quercitol is therefore *l*-deoxy-*l*-inositol. H. W.

**Production of steryl glucosides.** H. LETTRÉ and A. HAGEDORN (Z. physiol. Chem., 1936, 242,

210—214; cf. MacCorquodale *et al.* A., 1930, 1036).—Cholesterol (I) successively boiled in anhyd.  $\text{Et}_2\text{O}$  with acetobromoglucose (II),  $\text{Ag}_2\text{O}$ , and  $\text{CaH}_2$  and acetylated gives *cholesteryl*tetra-acetylglucoside, m.p. 159—160°,  $[\alpha]_D^{25}$  —23.1° in  $\text{CHCl}_3$ . Similarly dihydro- and dehydro-ergosterol give *dihydro*-, m.p. 187—188°,  $[\alpha]_D^{25}$  —19.4° in  $\text{CHCl}_3$ , and *dehydro-ergosteryl*tetra-acetylglucoside (III), m.p. 167—168°  $[\alpha]_D^{25}$  +62.4° in  $\text{CHCl}_3$ , respectively, and (I) with acetobromolactose yields, after acetylation, the *hepta-acetate*, m.p. 195°,  $[\alpha]_D^{25}$  —16.3°, of *cholesteryl-lactoside*, m.p. 260° (decomp.),  $[\alpha]_D^{25}$  —37.8°. Together with (III) a substance, m.p. 159—160°, is produced. The glucoside of cholesteryl oxide with hot  $\text{Ac}_2\text{O}$  and  $\text{NaOAc}$  gives 5-hydroxy-6-acetoxy-3-tetra-acetyl- $\beta$ -glucosidocholestan (IV), m.p. 212—213°,  $[\alpha]_D^{25}$  —26.4°, also obtained by the interaction of cholestanetriol and (II) followed by acetylation. (IV) with Na in  $\text{EtOH}$  gives *cholestanetriol-3-glucoside*, m.p. 263—265° (decomp.), which yields lather-producing solutions in  $\text{H}_2\text{O}$ . The other glucosides are  $\text{H}_2\text{O}$ -insol. Ergosterylglucoside acquires no antirachitic power on ultra-violet irradiation.

W. McC.

**Sterol group. XXVI. 7-Methylenecholesterol.** B. BANN, I. M. HEILBRON, and F. S. SPRING (J.C.S., 1936, 1274—1276).—7-Ketocholesteryl acetate (I) + 3 mols. of  $\text{MgMeI}$  gives 7-hydroxy-7-methyl-cholesterol (II), m.p. 165° (3-monobenzoate, m.p. 175°; 3-monoacetate, m.p. 164°). Dehydration of the monobenzoate by  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_2\text{Cl}$  or the Darzens method or sublimation in a high vac. gives 7-methylenecholesteryl benzoate (III;  $\text{R}=\text{Bz}$ ), m.p. 141°, hydrolysed to 7-methylenecholesterol (III;  $\text{R}=\text{H}$ ), m.p. 85° (3:5-dinitrobenzoate, m.p. 162°; acetate, m.p. 62—64°), directly isolable from the mother-liquor of (II) and the sole product of (I)+excess of  $\text{MgMeI}$ , which after irradiation was antirachitically inactive. F. R.

**Micro-determination of cholesterol.**—See this vol., 1436.

**Rates of isomerisation and of hydrogen isotope exchange in unsaturated nitriles.**—See this vol., 1344.

**Pentadeuterobenzoic acid.** H. ERLÉNMEYER and A. EPPRECHT (Helv. Chim. Acta, 1936, 19, 1056—1059; cf. this vol., 983).—The following consts. of  $\text{C}_6\text{D}_5\cdot\text{CO}_2\text{H}$  and  $\text{BzOH}$ , respectively, are recorded: m.p. 120.9° and 121.7°; solubility in 100 c.c. of  $\text{H}_2\text{O}$  at 18°, 0.34 and 0.28 g.; mol. heat of combustion, 761.38 and 771.4 kg.-cal.; heat of formation from the elements, 106.12 and 91.0 kg.-cal.; normal acidity potential,  $205.7 \pm 0.3$  and  $205.6 \pm 0.3$  mv. H. W.

**Asymmetric carbon atom  $\text{CHDR}^n\text{R}^m$ . III. Phenylpentadeuterophenylacetic acid.** H. ERLÉNMEYER and H. SCHENKEL (Helv. Chim. Acta, 1936, 19, 1169—1170; cf. this vol., 467, 604).—*l*- $\text{CHPhBr}\cdot\text{CO}_2\text{H}$ ,  $[\alpha]_D^{20}$  —145° in  $\text{C}_6\text{H}_6$ , is converted by  $\text{C}_6\text{D}_6$  in presence of Zn dust into *phenylpentadeuterophenylacetic acid*,  $\text{C}_6\text{D}_5\cdot\text{CHPh}\cdot\text{CO}_2\text{H}$ , m.p. 144°,  $[\alpha]_D^{20} \pm 0^\circ$ , which could not be resolved into its optical antipodes by morphine or strychnine. H. W.

**Halogenation of *o*-sulphobenzoic anhydride.** D. TWISS and L. H. FARINHOLT (J. Amer. Chem. Soc., 1936, 58, 1561—1565).—3-Bromo- (I), m.p. 175—176°, 3:6-dichloro- (II), m.p. 121—122°, 3:6-dibromo- (III), m.p. 167—168°, 3:6-di-iodo- (IV), m.p. 243—245°, 3:5:6-tribromo- (V), m.p. 224°, 3:5:6-tri-iodo- (VI), m.p. 287—288°, tetrachloro-, m.p. 158—159°, tetrabromo-, m.p. 216—217°, and tetra-iodo- (VII), decomp. gradually about 300°, *o*-sulphobenzoic anhydrides are prepared by halogenation of *o*-SO<sub>3</sub>H·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H, its anhydride, or, more conveniently, its NH<sub>4</sub> H salt [obtained by hydrolysis (dil. HCl) of saccharin] in (usually) 60% oleum at 150—180°. In some cases I is used as catalyst and the anhydrides are purified by conversion into the corresponding (NH<sub>4</sub>)<sub>2</sub> salt and subsequent treatment with SOCl<sub>2</sub>. All except (VII) are readily hydrolysed even by atm. moisture to the acids. The positions of the halogen atoms are determined by removal of the SO<sub>3</sub>H from the acids by aq. H<sub>2</sub>SO<sub>4</sub> at 200—210°; (I) thus gives *m*-C<sub>6</sub>H<sub>4</sub>·Br·CO<sub>2</sub>H; (II), 2:5-C<sub>6</sub>H<sub>3</sub>Cl<sub>2</sub>·CO<sub>2</sub>H and a little *p*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>; (III), 2:5-C<sub>6</sub>H<sub>3</sub>Br<sub>2</sub>·CO<sub>2</sub>H; (V), 2:3:5-C<sub>6</sub>H<sub>2</sub>Br<sub>3</sub>·CO<sub>2</sub>H; the I-derivatives are destroyed. Saturation of a conc. solution of tetraiodo-*o*-sulphobenzoic acid in aq. NH<sub>3</sub> with H<sub>2</sub>S gives (NH<sub>4</sub>)<sub>2</sub> 3:5:6-tri-iodo- [converted by conc. H<sub>2</sub>SO<sub>4</sub> at 160° into (VI)] and di-iodo-*o*-sulphobenzoate [which with conc. H<sub>2</sub>SO<sub>4</sub> at 150° affords a di-iodo-*o*-sulphobenzoic anhydride, m.p. 221—223°, different from (IV)]. H. B.

**Manufacture of basic esters of polyarylacetic acids.**—See B., 1936, 975.

**Agents of capillary activity [cyclohexylaliphatic acids].**—See B., 1936, 975.

**Valency problem of the quinquivalent phosphorus atom.** II. L. ANSCHUTZ, F. KOENIG, F. OTTO, and H. WALBRECHT (Annalen, 1936, 525, 297—311; cf. A., 1930, 1429).—The peculiar reactivity of one Cl of PCl<sub>5</sub> is due to electrostatic repulsion of the five electronegative Cl and not to a special type of linking of one Cl. In accordance with this view, the reactivity is depressed if Cl is replaced by OPh or substituted OPh. This is proved for the reaction of OPh·PCl<sub>4</sub>, (OPh)<sub>2</sub>PCl<sub>3</sub>, *o*-COCl·C<sub>6</sub>H<sub>4</sub>·O·PCl<sub>4</sub>, and *p*-OMe·C<sub>6</sub>H<sub>4</sub>·O·PCl<sub>4</sub> with H<sub>2</sub>O, EtOH, PhOH, *o*-OH·C<sub>6</sub>H<sub>4</sub>·COCl (I), and indene (II). Chloroindanyldiphosphorus tetrachloride is purified by pptn. by ligroin from warm PhNO<sub>2</sub>, and then reacts slowly with (I) and not at all with (II), but rapidly with H<sub>2</sub>O, EtOH, or PhOH by loss of HCl from the nucleus. The following are described. Ph<sub>3</sub>PO<sub>4</sub>, m.p. 45°; *salicylic acid phosphate* ("phosphosal"); *o*-CO<sub>2</sub>H·C<sub>6</sub>H<sub>4</sub>·O·PO<sub>3</sub>H<sub>2</sub>; *o*-anisoylphosphorus dichloride, b.p. 130—131°/13 mm., and tetrachloride, cryst.

R. S. C.

**Derivatives of  $\beta$ -amino- $\alpha$ -hydroxy- $\alpha$ -phenylpropionic acid.** B. CROCCA (Gazzetta, 1936, 66, 533—539).—CH<sub>2</sub>BzCl, HCN, and NH<sub>3</sub> yield  $\beta$ -chloro- $\alpha$ -hydroxy- $\alpha$ -phenylpropionic acid, m.p. 132°. This with aq. NHMe<sub>2</sub> (reaction completed at 110°) gives the NH<sub>2</sub>Me<sub>2</sub> salt, m.p. 251° (decomp.), of  $\beta$ -dimethylamino- $\alpha$ -hydroxy- $\alpha$ -phenylpropionic acid, of which the *Me*, b.p. 155—156°/14—15 mm., and *Pr*<sup>a</sup>, b.p. 171—172°/14—15 mm., esters yield respectively

(BzCl) *Me* (I), m.p. 163° (decomp.), and *Pr*<sup>a</sup>  $\beta$ -dimethylamino- $\alpha$ -benzyloxy- $\alpha$ -phenylpropionate hydrochloride (II), m.p. 177—178° (decomp.). *Pr*<sup>a</sup>  $\beta$ -dimethyl- (III), m.p. 136°, and  $\beta$ -diethyl-amino- $\alpha$ -acetoxy- $\alpha$ -phenylpropionate hydrochloride (IV), m.p. 134°, are obtained similarly. *Pr*<sup>a</sup>  $\beta$ -chloro- $\alpha$ -hydroxy- $\alpha$ -phenylpropionate, b.p. 173°/14—15 mm., with NHMe<sub>2</sub> at 100° gives  $\beta$ -dimethylamino- $\alpha$ -hydroxy- $\alpha$ -phenylpropiondimethylamide, b.p. 173°/14—15 mm. (I) and (II) are surface anaesthetics, and, intramuscularly, antipyretics; (III) also, subcutaneously, has depressor action, as, in a less degree, has (IV), with increased toxicity. E. W. W.

**Constitution of isomeric dichlorofluorenone-carboxylic acids formed by the action of sulphuric acid on 3:3'-dichlorodiphenic acid.** E. H. HUNTRESS and E. R. ATKINSON (J. Amer. Chem. Soc., 1936, 58, 1514—1518).—The keto-acid, C<sub>14</sub>H<sub>6</sub>O<sub>3</sub>Cl<sub>2</sub>, previously obtained (A., 1933, 1293) from 3:3'-dichlorodiphenic acid (I) and conc. H<sub>2</sub>SO<sub>4</sub> at 170°, is 1:6-dichlorofluorenone-4-carboxylic acid (II), new m.p. 248—249°, which results by isomerisation of the first-formed 1:6-dichlorofluorenone-5-carboxylic acid (III). The inconsistent titration (*loc. cit.*) of (II) is due to solvation. Dehydration of (I) with conc. H<sub>2</sub>SO<sub>4</sub> at 80—90°/24 hr., 95—104°/1 hr., or 125°/1 hr. gives (III), but at 125°/5 hr., 135—145°/4 hr., or 150—160°/1 hr., (II) results. Isomerisation does not occur with H<sub>3</sub>PO<sub>4</sub> at 215°; (I) thus affords (III) whilst 5:5'-dichlorodiphenic acid (IV) yields (II). 1:6-Dichloro-5-aminofluorenone (*loc. cit.*) is deaminated to 1:6-dichlorofluorenone (V). (II) and conc. H<sub>2</sub>SO<sub>4</sub> at 200—215° give 4:6-dichlorofluorenone (VI) (and a little unidentified material), also similarly obtained from (I), (III), and (IV) at about 200°, (V) at 150° (rearrangement not complete at 125°), and 1:8-dichlorofluorenone (VII) at 180—190°. Neither decarboxylation nor rearrangement occurs with (II) and H<sub>3</sub>PO<sub>4</sub>. Distillation of the Ca salts of (I) and (IV) gives (VII) and (VI), respectively. H. B.

**Condensation of aldehydes with malonic acid in the presence of organic bases.** Condensation of (V) anisaldehyde, (VI) *p*-hydroxybenzaldehyde, (VII) *m*-hydroxybenzaldehyde. K. C. PANDYA and T. A. VAHIDY (Proc. Indian Acad. Sci., 1936, 4, A, 134—139, 140—143, 144—146).—V. Condensation of anisaldehyde with CH<sub>2</sub>(CO<sub>2</sub>H)<sub>2</sub> using C<sub>5</sub>H<sub>5</sub>N, lutidine, and isoquinoline gives *p*-methoxycinnamic acid but with other bases the first product is anisylidenemalonic acid. Condensation also occurs without using a base.

VI. With *p*-OH·C<sub>6</sub>H<sub>4</sub>·CHO, similar results are obtained, the amount of product, either *p*-hydroxycinnamic or the *p*-coumaric acid, being increased by using a base.

VII. The yields of condensation product with different bases are compared, C<sub>5</sub>H<sub>5</sub>N giving the best yield at the optimum temp. 105—110°. F. R. S.

**Non-existence of multiplanar cyclohexane rings.** R. D. DESAI and R. F. HUNTER (Nature, 1936, 138, 548; cf. A., 1935, 1495; this vol., 831, 846).—4:4-Dimethylcyclohexane-1-carboxylic-1-acetic acid and -1:1-diacetic acid, now synthesised from 4:4-dimethylcyclohexanone, each exists in one form only,

thus supporting the uniplanar structure of the *cyclohexane* ring. L. S. T.

**Sachse-Mohr theory of the configuration of cyclohexane and the application of the Bredt rule to tetrahydro[iso]phthalic anhydride.** J. BREDT (J. pr. Chem., 1936, [ii], 147, 22—28).—Theoretical. Interconversion of boat into chair forms of a  $C_6$  ring occurs by way of the "sofa" form (A) and the mol. is never planar. By analogy with other systems it is inferred that the anhydride of tetrahydroisophthalic acid is intermol., and that an eight-membered ring containing one O and bridged across the 1:5 positions by one C cannot exist with the bridge containing a double linking. R. S. C.

**Chloral derivatives of salicylic acid.** N. M. SHAH and R. L. ALIMCHANDANI (J. Indian Chem. Soc., 1936, 13, 475—477).— $o\text{-OMe}\cdot C_6H_4\cdot CO_2H$  and chloral in conc.  $H_2SO_4$  give 2-methoxy-5- $\beta\beta$ -dichloro- $\alpha$ -hydroxyethylbenzoic acid (I), m.p.  $224^\circ$  (lit.  $216^\circ$ ), and a sulphonic acid, converted into (I) by boiling in  $H_2O$ . Other salicylic acid derivatives do not undergo this condensation. (I) yields by reduction 2-methoxy-5- $\beta\beta$ -dichloroethylbenzoic acid (II), m.p.  $134\text{—}135^\circ$  (lit.  $127^\circ$ ), and by  $H_2SO_4$  at  $100^\circ$  2-methoxy- $\alpha\beta\beta\beta$ -tetrachloroethylbenzoic acid, m.p.  $138^\circ$  (lit.  $132^\circ$ ), and a small amount of a substance, m.p.  $177^\circ$ . (II) and conc.  $H_2SO_4$  at  $100^\circ$  give 3-carboxy-4-methoxyphenylacetic acid,  $+H_2O$ , m.p.  $141\text{—}142^\circ$ , and anhyd., m.p.  $153^\circ$ . R. S. C.

**Isatdiazide.** A. DARAPSKY and B. GAUDIAN (J. pr. Chem., 1936, [ii], 147, 43—52).—Phthalyl chloride (I) and aq.  $NaN_3$  give isatdiazide,  $o\text{-N}_3\cdot CO\cdot C_6H_4\cdot NH\cdot CO\cdot N_3$  (II), m.p.  $101^\circ$ , and a trace of (?) phthalyl azide. Probably  $o\text{-N}_3\cdot CO\cdot C_6H_4\cdot NCO$  is first formed which then reacts with  $HN_3$ , liberated from  $NaN_3$  by products of hydrolysis of (I). With hot dil. aq.  $NaOH$  (II) gives anthranilic acid and with  $NH_2Ph$  at  $100^\circ$  the dianilide, m.p.  $222^\circ$ , which is stable to acid and alkali, but with conc.  $HCl$  at  $200\text{—}220^\circ$  gives  $NH_2Ph$  and 2:4-diketo-3-phenyltetrahydroquinazoline, m.p.  $272^\circ$ . With hot  $EtOH$  (II) gives  $o$ -phenylenediurethane, hydrolysed by  $2N\text{-}NaOH$  to  $o$ -phenylenecarbamide,  $o\text{-C}_6H_4(NH)_2CO$ , m.p.  $>300^\circ$ . With conc.  $NH_3$  (II) gives 2:4-diketotetrahydroquinazoline (III) and with  $N_2H_4$  3-amino-2:4-diketotetrahydroquinazoline, m.p.  $>280^\circ$  [benzylidene derivative, m.p.  $245\text{—}246^\circ$  (lit.  $240^\circ$ )]; with  $HNO_2$  gives  $N_2O$  and (III)]. R. S. C.

**Synthesis of substances of possible physiological activity.** L. F. FIESER, M. FIESER, E. B. HERSHBERG, H. L. HOLMES, and M. S. NEWMAN (Science, 1936, 83, 558).—Condensation of  $(CH_3\cdot CO)_2O$  (I) with  $\alpha\text{-C}_{10}H_7\cdot OMe$  gives a suitable starting material for the synthesis of 9-methoxyphenanthrene-1:2-dicarboxylic anhydride, m.p.  $249\text{—}250^\circ$  (corr.), by reduction, condensation of the ester with  $Et_2C_2O_4$ , cyclisation, and dehydrogenation. The 6-methoxy- and 6:7-dimethoxy-derivatives of octahydrophenanthrene-11:12-dicarboxylic anhydride were prepared by addition of butadiene (II) to the unsaturated anhydrides

obtained from anisole and from veratrole by condensation with (I), reduction, ester condensation, and cyclisation. The ethers were demethylated after hydrogenation of the active ethylenic linking. 7-Hydroxy-6-methyloctahydrophenanthrene-11:12-dicarboxylic anhydride, m.p.  $134.5\text{—}135.5^\circ$  (corr.), was prepared similarly from  $\gamma$ -4-methoxy-3-methylphenylbutyric acid. Phenanthrene-1:2-dicarboxylic anhydride is converted into 1':3'-diketo-1:2-cyclopentenophenanthrene by condensation of the  $Me_2$  ester with  $EtOAc$ . 1':3'-Diketo-3:4-cyclopentenophenanthrene, m.p.  $201.4\text{—}202^\circ$  (corr.), is obtained similarly. Chrysene, 2:3-dimethyl-6:7-accechrysene, m.p.  $222.6\text{—}223.1^\circ$  (corr.), and 6:7-dimethyl-3:4-benzophenanthrene, m.p.  $94.5\text{—}95^\circ$  (corr.), have been obtained by extensions of the hydrocarbon synthesis developed by Fieser and Hershberg (this vol., 203).  $o\text{-C}_6H_4Me\cdot MgBr$  and 1:2- $C_{10}H_6(CO)_2O$  give a keto-acid (decarboxylated to  $\beta$ - $o$ -toluoylnaphthalene), the ester of which is converted ( $MgMoX$ ; reduction; cyclisation; reduction) into 5:10-dimethyl-1:2-benzanthracene, m.p.  $147\text{—}147.5^\circ$  (corr.) [picrate, m.p.  $173.7\text{—}174.2^\circ$  (corr.)]. Addition of (II) and its 2:3- $Me_2$  derivative to  $Et$  3:4-dihydro-1-naphthoate affords, after hydrolysis, 5:8:9:10:13:14-hexahydrophenanthrene-13-carboxylic acid (morphine numbering), m.p.  $137\text{—}137.5^\circ$  (corr.), and its 6:7- $Me_2$  derivative, m.p.  $162\text{—}162.5^\circ$  (corr.). On dehydrogenation, these yielded phenanthrene and 2:3-dimethylphenanthrene respectively. L. S. T.

**$\alpha\delta$ -Diarylbutadienes and related compounds.** II.  $\alpha\delta$ -Diarylbutadiene- $\alpha\beta$ -dicarboxylic anhydrides. E. FRIEDMANN and W. E. VAN HEYNINGEN (J. pr. Chem., 1936, [ii], 146, 166—178; see this vol., 1371).— $CH_3Ph\cdot CO_2H$  and  $CHPh\cdot CH\cdot CO_2H$  in boiling  $Ac_2O$  give 46.5% of  $\alpha\delta$ -diphenylbutadiene- $\alpha\beta$ -dicarboxylic [ $\beta$ -carboxy- $\alpha\delta$ -diphenylpentadienic, phenylstyrylmalic] anhydride (I), m.p.  $137.5^\circ$ . With warm alkali this gives the  $Na_2$ ,  $+4H_2O$ , and  $K_2$  (II),  $+2H_2O$ , salts of the corresponding acid. Acidification of (II) in cold  $H_2O$  regenerates (I). Hydrogenation (colloidal Pd) of (II) causes absorption of 2  $H_2$ .  $\alpha$ -Phenyl- $\delta$ -p-anisyl- (III), m.p.  $176^\circ$  ( $Na_2$ ,  $+3H_2O$ , and  $K_2$  salt,  $+2H_2O$ , of the corresponding acid), and -2-furoylbutadiene- $\alpha\beta$ -dicarboxylic anhydride, m.p.  $174^\circ$ , are similarly prepared. The absorption spectra of (I) and (II) and of the  $K_2$  salts show the bathochromic effect of the OMe. R. S. C.

**Diphenyl series.** IX. Nitration of 2:4'-derivatives of diphenyl. C. FINZI and V. BELLAVITA (Gazzetta, 1936, 66, 421—429).—Diphenyl-2:4'-dicarboxylic acid (I) (dichloride, m.p.  $69\text{—}70^\circ$ ; diamide, m.p.  $233^\circ$ ; dianilide, m.p.  $280\text{—}281^\circ$ ; di-p-toluidide, m.p.  $259\text{—}260^\circ$ ;  $Me_2$ , m.p.  $79\text{—}80^\circ$ , and  $Et_2$  esters) is converted by  $H_2SO_4$  and  $EtNO_3$  into the 4- $NO_2$ -derivative (II), new m.p.  $284\text{—}285^\circ$ , and the 4:2'-( $NO_2$ ) $_2$ -derivative (dichloride; diamide, decomp.  $215^\circ$ ). 4-Nitro-2:4'-diaminodiphenyl (A., 1932, 1025) yields (Sandmeyer) 4-nitro-2:4'-dicyanodiphenyl, m.p.  $238\text{—}239^\circ$ , hydrolysed to (II). When 4:2'-dinitrodiphenyl-2:4'-dicarboxylic acid and 2-nitrodiphenyl-2'-carboxylic acid are heated with Cu chromite, they eliminate an  $NO_2$ -group, forming 2-nitrofluorenone and fluorenone, respectively; (I), however, yields di-

phenyl-4-carboxylic acid and  $\text{Ph}_2$ , whilst (II) gives 4-nitrodiphenyl. E. W. W.

**Nitrogenous heterocyclic rings. XXV. *m*-Phenylenedipropionic acid and *m*-diacetylbenzene.** P. RUGGLI and A. STAUB (Helv. Chem. Acta, 1936, 19, 962—972; cf. this vol., 866).—Addition of Br to *m*-phenylenediacrylic acid in AcOH or EtOAc gives the tetrabromide, m.p. 225—227°, purified with difficulty owing to the ready loss of HBr in warm solvents. It is therefore preferable to transform its Me ester, best in EtOAc, into Me<sub>2</sub> *m*-phenylenedi- $\alpha$ - $\beta$ -dibromopropionate (I), m.p. 146°, transformed by  $\text{C}_5\text{H}_5\text{N}$  alone into a brown oil and by  $\text{C}_5\text{H}_5\text{N}$ -EtOH (1:3) into Me<sub>2</sub> *m*-phenylenedimonobromoacrylate,  $\text{m-C}_6\text{H}_4(\text{CH}:\text{CBr}:\text{CO}_2\text{Me})_2$ , m.p. 87°. *m*-Phenylenedipropionic acid (II), m.p. 209° [Me<sub>2</sub> (III), m.p. 93°, and Et., m.p. 56°, ester], is best obtained by rapidly adding 2 mols. of KOH in EtOH to (I) dissolved in much boiling EtOH and then slowly adding 4 more mols. In the first phase of the change only KBr separates, followed after addition of a further 2 mols. of KOH by the *K* salt of *m*-phenylenedimonobromoacrylic acid, m.p. 215°; this is succeeded by the *K* salt of (II), followed by that of *phenylene-1-propionic-3-monobromoacrylic acid*, m.p. 161° (dihydrate, m.p. 67°). Treatment of (II) with conc.  $\text{H}_2\text{SO}_4$  at room temp. yields the unstable isophthaloyldiacetic acid (IV),  $\text{m-C}_6\text{H}_4(\text{CO}\cdot\text{CH}_2\cdot\text{CO}_2\text{H})_2$ , m.p. 116° (decomp.) [Me<sub>2</sub> ester (V), m.p. 68°, best obtained by hydration of (III)]. (IV) and  $\text{NHPh}\cdot\text{NH}_2$  in EtOH at 0° afford the diphenylhydrazone of *m*-acetylbenzoylacetic acid, m.p. 210°, and *m*-diacetylbenzenediphenylhydrazone (VI), m.p. 115°, separates from the mother-liquors when warmed to room temp.; if the change occurs directly at room temp. 1-phenyl-3-*m*-acetylphenylpyrazolonephenylhydrazone, m.p. 230—232° (decomp.), separates and (VI) is obtained from the mother-liquors. (VI) and  $\text{NHPh}\cdot\text{NH}_2$  in boiling EtOH give *m*-phenylene-3:3'-di(phenylpyrazolone), m.p. 263°, also derived from (III); (II) and  $\text{NHPh}\cdot\text{NH}_2$  in EtOH yield the diphenylhydrazine salt, m.p. 166°. (IV) and  $\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}_2$  at 0° yield the disemicarbazone of (IV), m.p. 232°, and *m*-diacetylbenzenedisemicarbazone, m.p. 240°, or the latter exclusively at room temp. (IV) and  $\text{NH}_2\text{OH}\cdot\text{HCl}$  in EtOH at 0° afford *m*-phenylene-3:3'-diisooxazolone, m.p. 190° when rapidly heated, and *m*-diacetylbenzenedioxime, m.p. 204°. Decarboxylation of (IV) is readily effected by 10%  $\text{H}_2\text{SO}_4$  at 100° whereby *m*-diacetylbenzene, m.p. 32°, is obtained in 70—77% yield. *m*-Acetylcinnamic acid, m.p. 128°, is described incidentally. H. W.

**Anthraquinone series.** Attempts to synthesise anthraquinonecarboxylic acids of the morindone type. P. C. MITTER and (MISS) T. SENGUPTA (J. Indian Chem. Soc., 1936, 13, 447—449).—Opianic acid, Me 5-bromosalicylate, and  $\text{H}_2\text{SO}_4$  give 3:4-dimethoxy- $\alpha$ -5'-bromo-2'-hydroxy-3'-carbomethoxyphenylphthalide, m.p. 215° (Ac derivative, m.p. 210°; corresponding 3'-carboxyphthalide, m.p. 253°), reduced by Zn-10% NaOH to 2:3-dimethoxy-6-2'-hydroxy-3'-carboxybenzylbenzoic acid (I), m.p. 225°. Ring-closure of (I) or its Br-derivative, m.p. 210°, is not effected by  $\text{H}_2\text{SO}_4$  or  $\text{P}_2\text{O}_5$ . Hot  $\text{H}_2\text{SO}_4$  sulphonates (I).

R. S. C.

**Use of amines for distinguishing geometrically isomeric aldioximes and their acyl derivatives.** C. R. HAUSER and E. JORDAN (J. Amer. Chem. Soc., 1936, 58, 1772—1776; cf. this vol., 1253).— $\alpha$ -CHAR:N·OAc (Ar=Ph, *o*- and *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4$ , *p*-OMe· $\text{C}_6\text{H}_4$ , 3:4- $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3$ , *o*- $\text{C}_6\text{H}_4\text{Cl}$ , *p*-NMe<sub>2</sub>· $\text{C}_6\text{H}_4$ ) are unaffected by  $\text{C}_5\text{H}_5\text{N}$  (usually at room temp.) but are converted into  $\alpha$ -oximes by  $\text{NH}_2\text{Bu}^a$  (at room temp.).  $\beta$ -CHAR:N·OAc (Ar=Ph, *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4$ , *p*-OMe· $\text{C}_6\text{H}_4$ , 3:4- $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3$ ) with  $\text{C}_5\text{H}_5\text{N}$  and  $\text{NH}_2\text{Bu}^a$  (heat developed) give nitriles (84—99% yield). It is thus possible to distinguish between the above geometrical isomerides. Similarly,  $\alpha$ -CHAR:N·O·CO·NHPh (I) (Ar=*m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4$ ; 3:4- $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3$ ),  $\alpha$ -CHAR:N·O·CO<sub>2</sub>Et (Ar=*p*-OMe· $\text{C}_6\text{H}_4$ , *o*- $\text{C}_6\text{H}_4\text{Cl}$ , *m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4$ , 3:4- $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3$ ) and  $\alpha$ -CHAR:N·OBz (Ar=*m*- $\text{NO}_2\cdot\text{C}_6\text{H}_4$ , 3:4- $\text{CH}_2\text{O}_2\cdot\text{C}_6\text{H}_3$ ) are unaffected by  $\text{C}_5\text{H}_5\text{N}$  and converted into  $\alpha$ -oxime by  $\text{NH}_2\text{Bu}^a$ , whilst the  $\beta$ -CHAR:N·O·CO·NHPh with  $\text{C}_5\text{H}_5\text{N}$  and  $\text{NH}_2\text{Bu}^a$  give the nitrile (also formed together with the  $\beta$ -oxime by the action of EtOH-NaOH at 25—30°).  $\text{NHPh}\cdot\text{CO}\cdot\text{NHBu}^a$  is also obtained from (I) and  $\text{NH}_2\text{Bu}^a$ . H. B.

**Ozonisation of aldehydes.**—See this vol., 1346.

**Photo-rearrangement of *o*-nitrobenzaldehyde to *o*-nitrobenzoic acid.**—See this vol., 1349.

**Reactions catalysed by aluminium chloride.**  
**XV. Preparation of saturated ketones by addition of acid chlorides to olefines and hydrogenation by aluminium chloride.** C. D. NENITZESCU and E. CIORĂNESCU (Ber., 1936, 69, [B], 1820—1823).— $\text{AlCl}_3$  is added gradually to a mixture of cyclopentene (I), AcCl, and cyclohexane (II) at  $-15^\circ$  in such a manner that HCl is not evolved; subsequently the temp. of the mixture is gradually raised to 70°, whereby cyclopentyl Me ketone, b.p. 55—56°/16 mm., is obtained in 50% yield. Reaction is  $\text{C}_5\text{H}_8 + \text{AcCl} = \text{C}_5\text{H}_8\text{ClAc} \xrightarrow{2\text{H}} \text{C}_5\text{H}_9\text{Ac} + \text{HCl}$  and  $2\text{C}_6\text{H}_{12} \rightarrow \text{C}_{12}\text{H}_{22} + 2\text{H}$ . The following ketones are prepared analogously: cyclohexyl Me, b.p. 183—184°; dicyclopentyl, b.p. 113—116°/14 mm., from cyclopentanecarboxyl chloride and (I), reduced (Clemmensen) to dicyclopentylmethane, b.p. 208—210°; cyclopentyl cyclohexyl, b.p. 128°/10 mm. (semicarbazone, m.p. 182°), whence cyclopentylcyclohexylmethane, b.p. 223—225°; 2-methylcyclopentyl cyclohexyl, b.p. 138—141°/20 mm. (semicarbazone, m.p. 190°), whence 2-methylcyclopentylcyclohexylmethane, b.p. 239—241°; 1-chloro-2-isovaleryl cyclohexane, b.p. 118—120°/14 mm., from cyclohexene (III), isovaleryl chloride (IV), and  $\text{AlCl}_3$  in  $\text{CS}_2$ , and cyclohexyl isobutyl ketone, b.p. 216—219°, from (III), (IV),  $\text{AlCl}_3$ , and (II), whence isomethylcyclohexane, b.p. 190—191°; 1-chloro-2-hexoyl cyclohexane, b.p. 140—143°/15 mm.; cyclohexyl amyl ketone, b.p. 122—125°/11 mm., whence *n*-heptylcyclohexane, b.p. 219—221°. H. W.

**Alicyclic compounds. III. Synthesis of  $\beta$ -ketoamines.** F. PIRRONE. **IV. Schiff's bases of 6- and 2- $\alpha$ -aminobenzyl-2-methylcyclohexanone.** F. PIRRONE and (SIGNA.) J. ROSELLI (Gazzetta, 1936, 66, 429—434, 435—440).—III. Interaction of PhCHO, cyclohexanone, and  $\text{NH}_2\text{Ph}$  yields 2- $\alpha$ -anilinobenzylcyclohexanone, m.p. 139—139.5° (oxime,

m.p. 154—155°; semicarbazone, m.p. 206—207°); cyclohexanone thus reacts in the ketonic form.

IV. PhCHO, 2-methylcyclohexanone, and  $\text{NH}_3$  yield 6-, m.p. 180—181° (no oxime or semicarbazone), and 2- $\alpha$ -benzylidencaminobenzyl-2-methylcyclohexanone, m.p. 127—128° (oxime, m.p. 238—239°; semicarbazone, m.p. 228—229°; picrate, m.p. 119—120°).

E. W. W.

Synthesis of 2:3-dimethyl-1:2:3:4:10:11-hexahydrofluorenone. S. FUJISE, Y. HORIUTI, and T. TAKAHASHI (Ber., 1936, 69, [B], 2102—2106).— $\beta\gamma$ -Dimethyl- $\Delta^{\alpha\gamma}$ -butadiene (I) and  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$  at 200° give 2-phenyl-4:5-dimethyl- $\Delta^4$ -tetrahydrobenzaldehyde, b.p. 171—173°/3.5 mm. (phenylhydrazone, m.p. 131—132°), oxidised by  $\text{AgNO}_3\text{--Ba(OH)}_2$  in  $\text{EtOH--H}_2\text{O}$  to 2-phenyl-4:5-dimethyl- $\Delta^4$ -tetrahydrobenzoic acid, m.p. 159—160°, in very poor yield. Treatment of (I) with  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$  at 180° gives Et 2-phenyl-4:5-dimethyl- $\Delta^4$ -tetrahydrobenzoate, b.p. 133—143°/1.5 mm., but the corresponding acid (II), m.p. 159—160°, is best obtained from (I) and  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  in xylene at 170°. (II) is hydrogenated ( $\text{PtO}_2$  in  $\text{EtOH}$ ) to 2-phenyl-4:5-dimethyl-hexahydrobenzoic acid, m.p. 128—129° [corresponding chloride (III), b.p. 163—164°/8 mm., and anilide, m.p. 146—149°]. (III) and  $\text{AlCl}_3$  in  $\text{CS}_2$  afford 2:3-dimethyl-1:2:3:4:10:11-hexahydrofluorenone, b.p. 157—159°/6 mm. (oxime, m.p. 147—151°; semicarbazone, m.p. 211—217°). H. W.

Grignard reagents: their reducing action and rates of addition. M. S. KHARASCH and S. WEINHOUSE (J. Org. Chem., 1936, 1, 209—230).—Previous results and mechanisms proposed for the reducing reactions of Grignard reagents are reviewed. The yield of  $\text{CHPh}_2\cdot\text{OH}$  obtained from  $\text{COPh}_2$  and  $\text{MgBu}^a\text{Br}$  is not appreciably affected by temp. or by the order in which the reactants are added to one another, but is affected somewhat by the concn. of the Grignard reagent and by the solvent used. The respective percentages of addition and of reduction ( $\text{CHPh}_2\cdot\text{OH}$ ) products formed when the following react with  $\text{COPh}_2$  in  $\text{Et}_2\text{O--C}_6\text{H}_6$  are given in parentheses:  $\text{MgPhBr}$  (90; 0),  $\text{CH}_3\text{Ph}\cdot\text{MgCl}$  (95; 0),  $\text{CH}_2\text{Ph}\cdot\text{MgBr}$  (52; 0),  $p\text{-C}_6\text{H}_4\text{Cl}\cdot\text{CH}_2\cdot\text{MgCl}$  (74; 0),  $\text{MgBu}^a\text{Cl}$  (63; 0),  $\text{CH}_3\cdot\text{CH}\cdot\text{CH}_2\cdot\text{MgBr}$  (72; 5),  $\text{cyclo-C}_6\text{H}_{11}\cdot\text{MgBr}$  (—; 7.1),  $\text{Ph}\cdot[\text{CH}_2]_3\cdot\text{MgBr}$  (38.5; 20.0),  $\text{Ph}\cdot[\text{CH}_2]_5\cdot\text{MgBr}$  (43.2; 32.6),  $\text{MgBu}^a\text{Br}$  (—; 58.6),  $\text{MgBu}^a\text{Cl}$  (—; 76.2),  $\text{MgBu}^b\text{Br}$  (—; 91.0),  $\text{cyclo-C}_5\text{H}_9\cdot\text{MgBr}$  (—; 94.0). Reduction of  $\text{COPh}_2$  by  $\text{MgRX}$  occurs only when R is of intermediate electronegativity. A mechanism involving dissociation of  $\text{MgRX}$  into  $\text{R}^-$  and  $(\text{MgX})$  and reduction by  $\text{R}^-$  is proposed and requires the reducing tendency to increase with decreasing electronegativity of R. "Competition" experiments show that the rates of addition of  $\text{MgRX}$  to  $\text{COPh}_2$  also increase with decreasing electronegativity of R. When R is weakly electronegative, the rapidity of the addition reaction is considered to exclude the reduction reaction from observation (cf. A., 1929, 675, 680). Reduction by  $\text{CPh}_3\cdot\text{MgX}$ , an exception to the foregoing generalisations, is considered to occur through a free-radical mechanism. The following appear to be new: diphenyl- $p$ -chlorobenzylcarbinol, m.p. 117.5—118.5°,

and diphenyl- $\gamma$ -phenylpropylcarbinol, m.p. 74—75°, dehydrated to  $\alpha\alpha\delta$ -triphenyl- $\Delta^a$ -butene. H. G. M.

Synthesis of phenanthrene derivatives. IV. Propionylphenanthrenes. W. E. BACHMANN and W. S. STRUVE (J. Amer. Chem. Soc., 1936, 58, 1659—1661).—Phenanthrene,  $\text{EtCOCl}$ , and  $\text{AlCl}_3$  in cold  $\text{PhNO}_2$  give 2- (I), m.p. 104—105°, and 3- (II), m.p. 55—57°, -propionylphenanthrene (picrates, m.p. 104.5—107° and 111—113°, respectively), oxidised (3%  $\text{NaOCl}$ ,  $\text{KOH}$ ) to phenanthrene-2- and -3-carboxylic acid, respectively. 9-Propionylphenanthrene, m.p. 55—57° (picrate, m.p. 105.5—107°), (I), and (II) are prepared from  $\text{MgEtBr}$  and 9-, 2-, and 3-cyanophenanthrene, respectively. (I) and (II) with  $\text{Br}$  in  $\text{Et}_2\text{O}$  at 0° afford 2-, m.p. 131.5—133°, and 3-, m.p. 117—118°, - $\alpha$ -bromopropionylphenanthrene, respectively, which with  $\text{CHNa}(\text{CO}_2\text{Et})_2$  in  $\text{C}_6\text{H}_6$ , subsequent hydrolysis (5%  $\text{NaOH}$ ), and decarboxylation give  $\beta$ -2-, m.p. 173—174°, and -3-, m.p. 144—146°, -phenanthrolylbutyric acid, respectively.

H. B.

Conversion of tolyl naphthyl ketones into methylbenzanthrenes. L. F. FISER and E. L. MARTIN (J. Amer. Chem. Soc., 1936, 58, 1443—1445).— $o$ -Tolyl  $\alpha\text{-C}_{10}\text{H}_7$  ketone (I), m.p. 52—53° (from  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{MgBr}$  and  $o\text{-C}_6\text{H}_4\text{Me}\cdot\text{CN}$ ), and  $m$ -tolyl  $\alpha\text{-C}_{10}\text{H}_7$  ketone, m.p. 72—73° (from  $m\text{-C}_6\text{H}_4\text{Me}\cdot\text{MgBr}$  and  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{COCl}$ ), with  $\text{AlCl}_3\text{+NaCl}$  at 150° both give 9-methylbenzanthrone (II). The conclusion of Mayer *et al.* regarding wandering of the Me group (A., 1930, 1042) is thus valid but is based on unsound

evidence since their (I) [and the (I) of Scholl and Seer (A., 1913, i, 56)] is  $o$ -tolyl  $\beta\text{-C}_{10}\text{H}_7$  ketone (III), m.p. 63—64° (now prepared from  $o\text{-C}_6\text{H}_4\text{Me}\cdot\text{MgBr}$  and  $\beta\text{-C}_{10}\text{H}_7\cdot\text{CN}$ ). It is probable that the Friedel-Crafts reaction between  $o\text{-C}_6\text{H}_4\text{Me}\cdot\text{COCl}$  and  $\text{C}_{10}\text{H}_8$  gives a mixture of (I) and (III).  $p$ -Tolyl  $\alpha\text{-C}_{10}\text{H}_7$  ketone, m.p. 83—84° (from  $\alpha\text{-C}_{10}\text{H}_7\cdot\text{MgBr}$  and  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CN}$ ), is converted by  $\text{AlCl}_3\text{+NaCl}$  into 10-methylbenzanthrone (IV), m.p. 158—159°;  $m$ -, m.p. 76—77°, and  $p$ -, m.p. 90—91°, tolyl  $\beta\text{-C}_{10}\text{H}_7$  ketones (from  $\beta\text{-C}_{10}\text{H}_7\cdot\text{CN}$  and  $\text{C}_6\text{H}_4\text{Me}\cdot\text{MgBr}$ ) and (III) do not similarly give benzanthrenes. (IV) is oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to 7-methylantranthraquinone-1-carboxylic acid (V), m.p. 310—312°, and thence [ $\text{HNO}_3$  ( $d$  1.1) at 200—210°] to anthraquinone-1:7-dicarboxylic acid, m.p. 346—348°. (II) similarly affords 6-methylantranthraquinone-1-carboxylic acid (VI), m.p. 264—266°, and anthraquinone-1:6-dicarboxylic acid, m.p. 336—338°. (V) and (VI) are both decarboxylated ( $\text{Cu}$ , quinoline) to 2-methylantranthraquinone. Anthraquinone-1:3-dicarboxylic acid, decomp. 320—325°, is prepared from  $m$ -xylene,  $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$ , and  $\text{AlCl}_3$ . H. B.

Benzanthrone derivatives. IV. New synthesis of benzanthrone derivatives. E. CLAR (Ber., 1936, 69, [B], 1686—1691).—Methylenanthrone (I) and maleic anhydride (II) in boiling  $\text{AcOH}$  give the adduct  $\text{C}_{23}\text{H}_{18}\text{O}_9$ , m.p. 190—192° (decomp.), whilst when melted together or heated in boiling  $\text{PhNO}_2$  they yield benzanthrone-2:3-dicarboxylic anhydride, m.p. 310° (corresponding anilide,

m.p. 288—292°, and *azine*, m.p. >360°). (I) and  $\text{CHPh}:\text{CH}:\text{CO}_2\text{H}$  in boiling  $\text{PhNO}_2$  afford 3-phenylbenzanthrone, m.p. 183—184°. Under similar conditions benzylidenanthrone and (II) yield 1-phenylbenzanthrone-2:3-dicarboxylic anhydride, m.p. 280°. 2'-Anthraquinonylmethylencanthrone, m.p. 279—280°, obtained from 2-chloromethylanthraquinone, anthrone, and piperidine in EtOH, condenses with (II) in boiling  $\text{PhNO}_2$  to 1:2'-anthraquinonylbenzanthrone-2:3-dicarboxylic anhydride, m.p. 316—317°. (I) and *endo*-9:10-*o*-phenylene-9:10-dihydro-1:4-anthraquinone in boiling xylene afford 2':3'-benzanthrone-2:3-endo-9:10-*o*-phenylene-9:10-dihydro-1:4-anthraquinone, m.p. >360°, which has little affinity for vegetable fibres. 2':3'-Benzanthrone-2:3-naphtha-1:4-quinone, m.p. 286°, from (I) and 2:3-dichloro-1:4-naphthaquinone in boiling  $\text{PhNO}_2$  or from 1:4-naphthaquinone, appears identical with the product from  $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$ , benzanthrone, and  $\text{AlCl}_3$ . Gradual addition of (I) to a boiling solution of chloranil in xylene gives 5:6-2:3-benzanthrone-2:3-dichloro-1:4-benzoquinone, m.p. 300°. If the reagents are used in inverse order and excess of (I) is employed the product is *di*-2':3'-2'':3''-benzanthrone-2:3-5:6-benzo-1:4-quinone, also obtained from (I) and *p*-benzoquinone in boiling  $\text{PhNO}_2$ .

H. W.

**Constitution and reactivity. XVI. Constitution of benzanthrone-6-sulphonic acid.** Kinetics of the sulphonation of benzanthrone. K. LAUER and K. IRIE (J. pr. Chem., 1936, [ii], 145, 281—286; cf. this vol., 297).—Benzanthrone and  $\text{H}_2\text{SO}_4$  at 140—150° give benzanthrone-9-sulphonic acid (*Na* salt), the structure of which is proved by chlorination ( $\text{HCl-KClO}_3$ ) to 9-chloro- and 3:9-dichloro-benzanthrone and by formation of a violanthrone with  $\text{KOH-EtOH}$ . Reaction velocities with 80—99% acid at 95—170° show that two sulphonating agents ( $\text{H}_2\text{SO}_4$  and  $\text{SO}_3$ ) are effecting the reaction.

R. S. C.

**Magnetochemical investigations of organic substances. XI. Bromobenzanthrone of Brass and Clar.** E. MÜLLER and W. WIESEMANN (Ber., 1936, 69, [B], 2173—2174).—Magnetic observations do not indicate the presence of a radical compound in the “uneven bromide” of benzanthrone (this vol., 726).

H. W.

**Chrysene. IV.** K. FUNKE and J. RISTIC (J. pr. Chem., 1936, [ii], 146, 151—158; cf. this vol., 1113).—Conversion of chrysene-2:8-dicarboxylic acid by aq.  $\text{KOH}$  at 210—220° into chrysene-2-carboxylic acid, m.p. 314°, proves the orientation of 2:8-dibromochrysene and all substances derived from it. 2-Acetylchrysene gives the 8-*Br*-derivative, m.p. 142°, which gives oils with  $\text{CuCN}$  in quinoline and is reduced (Clemmensen) to 2-ethylchrysene (I). (I) gives (Friedel-Crafts) 2-acetyl-8-ethylchrysene, m.p. 131°, reduced to 2:8-diethylchrysene, m.p. 145°, and oxidised only to the quinone. 2-Benzoyl-8-ethylchrysene, m.p. 130°, is similarly prepared. 2:8-Dibenzoylchrysene (modified prep.) with  $\text{AlCl}_3$  gives a dye, not isolated, and a trace of a substance,  $\text{C}_{60}\text{H}_{36}\text{O}_6$ , m.p. 260°.

R. S. C.

**Unsaturated sulphur compounds. III.  $\alpha\beta$ -Unsaturated ketosulphones.** E. P. KOHLER

and R. G. LARSEN (J. Amer. Chem. Soc., 1936, 58, 1518—1522).— $\text{COPh}:\text{CH}_2:\text{CHPh}:\text{SO}_2\text{Ph}$  (I) (from  $\text{CHPh}:\text{CH}:\text{COPh}$  and  $\text{PhSO}_2\text{H}$  in EtOH) and Br in  $\text{CHCl}_3$  give diastereoisomeric *Ph*  $\beta$ -bromo- $\beta$ -benzoyl- $\alpha$ -phenylethyl sulphones, m.p. 189° (90%) and 209° (<3%; also obtained from  $\text{CHPh}:\text{CBr}:\text{COPh}$  and  $\text{PhSO}_2\text{H}$  in EtOH), both of which are converted (at different rates) by KOAc in MeOH or AcOH into the yellow trans-*Ph*  $\beta$ -benzoyl- $\alpha$ -phenylvinyl sulphone (II), m.p. 151°; the colourless cis-form (III), m.p. 132°, is prepared from  $\text{CPh}_2:\text{C}:\text{COPh}$  and  $\text{PhSO}_2\text{H}$  in MeOH. (III) is converted by NaOMe into (II), whilst (II) or (III) in  $\text{CHCl}_3$ +I in sunlight give an equilibrium mixture [mainly (II)]. *Ph*  $\alpha$ -chloro-, m.p. 175°, and  $\alpha$ -bromo-, m.p. 124° [decomp. to (II)],  $\beta$ -benzoyl- $\alpha$ -phenylethyl sulphones are obtained from (II) and AcOH-HHal. (II) and  $\text{MgPhBr}$  in the cold afford *Ph*  $\gamma$ -hydroxy- $\gamma\gamma$ -triphenyl- $\Delta^a$ -propenyl sulphone (IV) (+2MeOH), m.p. about 107°, m.p. (MeOH-free) 133° (acetate, m.p. 168°), reduced ( $\text{H}_2$ , Pd- $\text{CaCO}_3$ , EtOAc) to the *propyl* sulphone, m.p. 223°, also prepared from (I) and  $\text{MgPhBr}$ . (IV) and a little AcCl in MeOH give the *Me ether*, m.p. 130°, oxidised ( $\text{KMnO}_4$ ,  $\text{COMe}_2$ , little AcOH) to  $\text{OMe}:\text{CPh}_2:\text{CO}_2\text{H}$ ; with HCl in  $\text{C}_6\text{H}_6$ , *Ph*  $\gamma$ -chloro- $\gamma\gamma$ -triphenyl- $\Delta^a$ -propenyl sulphone, m.p. about 142° [decomp. to 1-benzenesulphonyl-1:3-diphenylindene, m.p. 171°, which is oxidised ( $\text{Na}_2\text{Cr}_2\text{O}_7$ , AcOH) to  $o\text{-C}_6\text{H}_4\text{Bz}_2$ ], results. (II) and  $\text{MgPhBr}$  in boiling  $\text{Et}_2\text{O}$  afford (IV) and *Ph*  $\gamma$ -hydroxy- $\alpha\beta\gamma$ -tetraphenylpropyl sulphone, stereoisomeric forms, m.p. 178° and 223° (? 196°), both of which are converted by AcOH- $\text{H}_2\text{SO}_4$  into 1:2:3-triphenylindene. (II) thus resembles  $\text{COPh}:\text{CH}:\text{CH}:\text{SO}_2\text{Ph}$  (A., 1935, 1241) except in the reaction with  $\text{MgPhBr}$ .

H. B.

**Transformation reactions of brominated derivatives of cholesterol. III. Bromination of cholestenone.** H. H. INHOFFEN (Ber., 1936, 69, [B], 2141—2147; cf. this vol., 1104).—Treatment of cholestenone (I) in  $\text{Et}_2\text{O}$  at 2° with Br in AcOH gives the dibromide (II),  $\text{C}_{27}\text{H}_{42}\text{OBr}_2$ , m.p. 162° (decomp.) (*loc. cit.*), and an isomeride, m.p. 133°, each of which is transformed into the enol acetate, m.p. 158—159°. Reaction generally occurs immediately but occasionally an induction period is observed. In presence of KOAc (I) does not react with Br; a preliminary enolisation due to HBr is therefore assumed, the enolic form probably being (A).

In confirmation, cholestenone enol acetate (Ruzicka *et al.*, this vol., 991) is transformed by Br in  $\text{Et}_2\text{O}$ -AcOH into (II) whereas in presence of KOAc the *Br*<sub>1</sub>-ketone (III),  $\text{C}_{27}\text{H}_{43}\text{OBr}$ , m.p. 132°, is produced. Bromination of (III) in presence of HBr gives (II). The mechanism of the production of (III) and thence of (II) is discussed.

H. W.

**Constituents of pyrethrum flowers. VI. Structure of pyrethrolone.** F. B. LAForge and H. L. HALLER (J. Amer. Chem. Soc., 1936, 58, 1777—1780; cf. B., 1936, 812).—Pyrethrolone (I) (3:5-dinitrobenzoate, m.p. 145°) is considered to be 5-hydroxy-3-methyl-2- $\Delta^a$ -pentadienyl- $\Delta^2$ -cyclopenten-

one (cf. Staudinger and Ruzicka, A., 1924, i, 523). Tetrahydropyretrolone [the 2-amyl- $\Delta^2$ -cyclopentenone] (II), b.p. 120—125°/0.25 mm., [ $\alpha$ ]<sub>D</sub><sup>20</sup> +11.9° in EtOH (cf. *loc. cit.*) (Me ether, b.p. 82°/0.35 mm.), prepared by hydrolysis (cold conc. aq. KHSO<sub>4</sub>+Et<sub>2</sub>O) of its semicarbazone, m.p. 196° [obtained by reduction of the semicarbazone of (I)], contains a quantity of *dl*-tetrahydropyretrolone (III) (semicarbazone, m.p. 170°); (III) is the sole product when hydrolysis is carried out at 100°. 5-Chloro-3-methyl-2-*n*-amyl- $\Delta^2$ -cyclopentenone, b.p. 97—100°/0.6 mm. [from (II) and SOCl<sub>2</sub>], is reduced (Zn dust, AcOH) to the optically inactive 3-methyl-2-*n*-amyl- $\Delta^2$ -cyclopentenone [dihydrojasnone] (cf. Treff and Werner, A., 1933, 1296; 1935, 750), which is similarly prepared from (III).

H. B.

$\beta$ -Methylenebutan- $\gamma$ -on- $\alpha$ -ol. H. GAULT and L. A. GERMANN (Compt. rend., 1936, 203, 514—516; cf. A., 1933, 1144).—Condensation of CH<sub>2</sub>O with CH<sub>3</sub>Ac·CH<sub>2</sub>·OH or CHAc·CH<sub>2</sub> in presence of K<sub>2</sub>CO<sub>3</sub> affords CH<sub>2</sub>:C(AC)·CH<sub>2</sub>·OH (cf. *loc. cit.*), which condenses with  $\beta\gamma$ -dimethyl- $\Delta^{\alpha\gamma}$ -butadiene to 4-hydroxymethyl-4-acetyl-1:2-dimethyl- $\Delta^1$ -cyclohexene, b.p. 155—157°/15 mm., and with  $\delta$ -methyl- $\Delta^{\alpha\gamma}$ -pentadiene to a mixture of 6-hydroxymethyl-6-acetyl-, b.p. 146—150°/12 mm., and 5-hydroxymethyl-5-acetyl-1:1-dimethyl- $\Delta^2$ -cyclohexene, b.p. 150—153°/12 mm., m.p. 71°.

F. O. H.

Alcoholic ammonia as a reagent for [condensation of] nitro-compounds and unsaturated ketones. D. E. WORRALL and C. J. BRADWAY (J. Amer. Chem. Soc., 1936, 58, 1607—1608).— $\gamma$ -Nitro- $\alpha$ -dibenzoyl- $\beta\delta$ -diarylpentanes (A) are obtained by prolonged interaction of MeNO<sub>2</sub> and an excess of CHAr:CH·COPh (except when Ar contains an *o*-substituent) in EtOH-NH<sub>3</sub>; the presence of H<sub>2</sub>O promotes reaction. The intermediate COPh·CH<sub>2</sub>·CHAr·CH<sub>2</sub>·NO<sub>2</sub> (Ar=*p*-OMe·C<sub>6</sub>H<sub>4</sub>·, m.p. 50—51°, and 3:4-CH<sub>2</sub>O<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>·, m.p. 94—95°) are isolable; these can be similarly condensed with CHAr:CH·COPh to (A). Compounds similar to (A) could not be prepared from EtNO<sub>2</sub> or CH<sub>2</sub>Ph·NO<sub>2</sub>. The following are described:  $\gamma$ -nitro- $\alpha$ -dibenzoyl- $\beta\delta$ -diphenyl-, stereoisomeric forms, m.p. 157—158° (I) and 229—230° (II), - $\beta\delta$ -dianisyl-, m.p. 211—212°, - $\beta\delta$ -di-3:4-methylenedioxyphenyl-, m.p. 192—193°, - $\beta\delta$ -di-*p*-bromophenyl-, m.p. 239—240°, - $\beta\delta$ -di-*p*-tolyl-, m.p. 209—210°, - $\beta\delta$ -di-*m*-bromophenyl-, m.p. 200—201°, - $\beta\delta$ -di-*m*-nitrophenyl-, m.p. 237—239°, and - $\beta\delta$ -dicinnamyl-, m.p. 216—218°; - $\beta$ -phenyl- $\delta$ -anisyl-, m.p. 205—206° (best prepared using CHPh:CH·COPh as the second component), - $\delta$ -3:4-methylenedioxyphenyl-, m.p. 218—219°, - $\delta$ -*m*-bromophenyl-, m.p. 227—228°, - $\delta$ -*p*-tolyl-, m.p. 191—192°, and - $\delta$ -*m*-nitrophenyl-, m.p. 219—220°; - $\beta$ -anisyl- $\delta$ -*p*-tolyl-, m.p. 196—197°; - $\beta$ -anisyl-, m.p. 189—190°, - $\beta$ -*m*-nitrophenyl-, m.p. 218—219°, - $\beta$ -*p*-tolyl-, m.p. 198—199°, and - $\beta$ -*m*-bromophenyl-, m.p. 215—216°. - $\delta$ -3:4-methylenedioxyphenyl-pentanes. (I) and Br in CHCl<sub>3</sub> and sunlight give a Br-derivative (? mixture), m.p. about 80°. (II) and Br in PhNO<sub>2</sub> afford the  $\beta$ -Br-derivative, m.p. 241—242° (decomp.); in MeOH-NaOMe the  $\gamma$ -Br-derivative, m.p. 205—206° results. The  $\gamma$ -nitro- $\alpha$ -di-*p*-bromobenzoyl- $\beta\delta$ -diphenylpentano

of Kohler and Williams (A., 1920, i, 59) is a mixture of isomerides, m.p. 151—152° and 218—219°.

H. B.

Sexual hormones. XVI. Esters of the testosterone and androsterone series. L. RUZICKA and A. WETTSTEIN [in part, with W. KLARER and J. MEYER]. XVII. Bromination of sterol and androstene derivatives. L. RUZICKA, W. BOSSHARD, W. H. FISCHER, and H. WIRZ (Helv. Chim. Acta, 1936, 19, 1141—1146, 1147—1153; cf. this vol., 991).—XVI. The following esters of testosterone are described: *formate*, m.p. 127—129° (corr.); *propionate*, m.p. 121—123° (corr.); *n-butyrate*, m.p. 111—113° (corr.); *isobutyrate*, m.p. 134—136° (corr.); *n-valerate*, m.p. 109—111° (corr.); *isovalerate*, m.p. 138—140° (corr.); *decanoate*, m.p. 55—57° (corr.); *palmitate*, m.p. 72—74° (corr.); *stearate*, m.p. 79—80° (corr.); *H succinate*, dimorphous, m.p. 183—185° (corr.) and 191—193° (corr.), respectively. *Androstane-3-cis-17-trans-diol disuccinate* has m.p. 139—140° (corr.). The Na and Li salts of androsterone succinate and the Na, K, and Li salts of androstane-3-cis-17-trans-diol 3-succinate are described. The physiological action of the esters is discussed.

XVII. Cholesterol dibromide in C<sub>6</sub>H<sub>6</sub> is converted by CrO<sub>3</sub> in AcOH-H<sub>2</sub>O at room temp. into  $\Delta^5$ -cholestenone dibromide, transformed by boiling aq. KOAc into 6-bromo- $\Delta^4$ -cholestenone (I), m.p. 130—131°, in about 10% yield. The absorption spectrum proves (I) to be an  $\alpha\beta$ -unsaturated ketone; it is hydrogenated to cholestenone and coprostanone. If more vigorous conditions are used in the prep. of (I) the product is cholestane-3:6-dione. Similarly, *trans*-dehydroandrosterone is brominated and oxidised to androstenedione dibromide, which in C<sub>6</sub>H<sub>6</sub> is transformed by boiling aq. KOAc into 6-bromo- $\Delta^4$ -androstene-3:17-dione, m.p. 170—171° (decomp.). Bromination of the requisite ketone in AcOH yields 2:2-dibromocholestanone, m.p. 194° (*quinoxaline* derivative, C<sub>33</sub>H<sub>48</sub>N<sub>2</sub>, m.p. 184°), 4:4-dibromo-, m.p. 143° (*quinoxaline* derivative, m.p. 200°), and 2:4:4-tribromo-, m.p. 180°, -*coprostanone*.  $\Delta^4$ -cholestenone in CCl<sub>4</sub> does not give a homogeneous product when treated with Br (1—2 mols.) but by use of a large excess of halogen (?) 2:4-dibromo- $\Delta^4$ -cholestenone, m.p. about 180°, is obtained. It does not give a yellow colour with C(NO<sub>2</sub>)<sub>4</sub> or react with o-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>.

H. W.

Proposed synthesis of equilenin. M. VANGHELOVICI (Chem. and Ind., 1936, 728).—The proposed path is, ergosterol  $\rightarrow$  neocergosterol  $\rightarrow$  dehydro- $\rightarrow$  acetyldidehydro-neocergosterol  $\rightarrow$  acetylequilenin  $\rightarrow$  equilenin.

H. W.

Constituents of the adrenal gland. V. Chemical identification of the androstane skeleton. VI. Methods of separation and isolation of the substances *Fa*, *II*, and *J*. T. REICHSTEIN (Helv. Chim. Acta, 1936, 19, 979—987, 1107—1126; cf. this vol., 475, 605, 704, 854).—V. Reduction (Clemmensen) under mild conditions of the diketone (I) C<sub>19</sub>H<sub>26</sub>O<sub>3</sub>, m.p. 178°, gives small amounts of a cryst. product, m.p. (indef.) 120—143°, oxidised to androstane-17-one and, mainly, a mixture of liquid hydrocarbons, C<sub>19</sub>H<sub>32</sub>, which is somewhat unsaturated and, after

hydrogenation, gives a small proportion of androstane, m.p. 49—51°. Similar results are obtained from androstanedione. The partial formulæ assigned previously to substances *A*, *C*, and *D* thus receive chemical confirmation. No information is afforded of the nature of the third O which is eliminated during the reduction. Zerevitinov determinations establish the presence of 1.14 active H in the OH-ketone (II)  $C_{19}H_{28-30}O_2$ , m.p. about 236° (corr.) (*loc. cit.*), and 0.15 active H in (I) so that (II) and (I) contain 1 OH and no OH, respectively. Further (II) in boiling  $C_6H_6$  containing  $C_5H_5N$  yields a 3 : 5-dinitrobenzoate, m.p. 257—258° (corr.), whereas (I) remains unchanged. Treatment of (I) with a large excess of  $NH_2OH \cdot AcOH$  at 130° gives the known dioxime (III) with non-cryst. material analyses of which accord with the presence of about 25% of (III) and 75% of a trioxime. Definite conclusions cannot yet be reached, but the presence of an O bridge, opened under the experimental conditions, is suggested.

VI. The dry residue of the "permutit fraction" of the entire gland is distributed between pentane and 30% MeOH, whereby the cortin activity passes entirely into the aq. layer, from which it is extracted by  $Et_2O$  after concn. of the acid liquor. The activity is driven from  $Et_2O$  into  $H_2O$ , leaving an "ether residue." Concn. and acidification of the aq. layer followed by extraction with  $Et_2O$  leads to concentrate  $C_{13}$ . The latter is treated with Girard's reagent and from the reactive portions four fractions of  $C_{17}A$  ketones are separated by varying the degree of acidity. The  $A$ -ketone-free residues are heated with the reagent and from the product the  $C_{17}B$  ketones are isolated. Substances *A*, *C*, and *D* are thus readily obtained. The product of the oxidation of *E* is identified as adrenosterone (IV) and it is therefore  $C_{21}H_{30-32}O_5$ . Substance *Fa*, m.p. about 215° (corr.; decomp.) depending largely on the manner of heating,  $[\alpha]_D$  about  $+200 \pm 8^\circ$  in EtOH, is  $C_{21}H_{28-30}O_5$ . Its

absorption spectrum shows it to be an  $\alpha\beta$ -unsaturated ketone. The cryst. form is very characteristic. It is physiologically inactive. Oxidation of it affords (IV). It appears identical with compound *F* of Wintersteiner and compound *E* of Kendall *et al.*, whose formulation is queried. Substance *H*, m.p. about 163—167°, is obtained from fraction  $C_{17}A.III$  by a process which cannot be reproduced with certainty. It appears to be an  $\alpha\beta$ -unsaturated ketone,  $C_{19}H_{26}O_4$  or  $C_{23}H_{32}O_5$ . It does not contain OEt. Examination of the "ether residue" (see above) with Girard's reagent is incomplete but (IV), and two further ketones, substances *K* and *L*, m.p. about 175° and about 255° (corr.), have been isolated. Substance *J*, m.p. 216—217° (corr.) after becoming opaque at about 120°, appears to be a polyhydric alcohol,  $C_{21}H_{34-36}O_3$ , since it is oxidised by  $CrO_3$  to a neutral product of much lower m.p. Its precipitability with digitonin indicates that it is a derivative of chole-

stanol. Reply is made to Mason *et al.* (this vol., 1117).

**6-Keto-3 : 5-diacetoxycholestanol.** F. SCHENCK (Z. physiol. Chem., 1936, 243, 119—120; cf. Windaus *et al.*, A., 1935, 1363).—The substance having m.p. 169—170°,  $[\alpha]_D^{20} -15.4^\circ$  in  $CHCl_3$ , obtained by oxidising cholesteryl acetate with  $CrO_3$  contains 2 Ac but no active H and hence is 6-keto-3 : 5-diacetoxycholestanol. 5-Hydroxy-6-keto-3-acetoxycholestanol has m.p. 230—231°,  $[\alpha]_D -55.8^\circ$  in  $CHCl_3$ . W. McC.

**Dioximes.** CXVI. G. PONZIO (Gazzetta, 1936, 66, 479—486; cf. this vol., 1363).—"Benzoylmethylglyoxime peroxide" (A., 1904, i, 427—428), now renamed phenylmethyltriketone-1 : 3-dioxime peroxide (I), new m.p. 161—162°, is converted by  $NH_2OH \cdot HCl$  in  $C_5H_5N$  into phenylmethyltriketone- $\alpha$ -trioxime (II) (A., 1922, i, 1038) [ $C \cdot H_5N$ , m.p. 130—140° (decomp.), and  $NHPh \cdot NH_2$ , m.p. 167—168° (decomp.), salts;  $Bz_3$  derivative, m.p. 132—133°]. "Oximinobenzoylmethylglyoxime peroxide" (*loc. cit.*), renamed as the oxime of (I), is similarly reduced to (II), and "anisoyl-" and "oximinobenzoyl-methylglyoxime peroxide," renamed as anisylmethyltriketone-1 : 3-dioxime peroxide and its oxime, are both reduced to anisylmethyltriketone-1 : 3-dioxime peroxide, m.p. 195° (decomp.) ( $Ac_3$ , m.p. 133—134°, and  $Bz_3$ , m.p. 150°, derivatives). E. W. W.

**System 3 : 4 : 3' : 4'-tetramethoxy- and 3 : 4 : 3' : 4'-bismethylenedioxy-benzophenone.** A. OLIVERIO (Rend. Semin. Fac. Sci. Univ. Cagliari, 1934, 4, 130—134; Chem. Zentr., 1935, ii, 3910).—A stable equimol. additive compound, m.p. 164°, and two eutectics, m.p. 141—141.5° and 135°, are described. H. N. R.

**Stereochemistry of deuterium compounds of the type, CHRR'. 2 : 3-Dideutero-camphane.** M. T. LEFFLER and R. ADAMS (J. Amer. Chem. Soc., 1936, 58, 1555—1558).—Reduction ( $H_2$ ,  $PtO_2$ , EtOAc) of *l*-bornylene, m.p. 105—106.5°,  $[\alpha]_D^{25} -9.57^\circ$  in EtOAc (which thus contains tricyclene), gives camphane, m.p. 145°,  $d_{440}^{25} 0.7458$ ,  $\alpha_D^{25} +0.02 \pm 0.01^\circ$  in EtOAc ( $l=1$ ) (due to some impurity); reduction with  $D_2$  under identical conditions affords 2 : 3-dideutero-camphane, m.p. 143°,  $d_{440}^{25} 0.7552$ , of the same rotation. There appears to be no evidence for the activity of CHDRR' compounds (cf. Billmann *et al.*, this vol., 855). H. B.

**Rotatory power of substituted camphoranilic acids.** M. SINGH (J. Indian Chem. Soc., 1936, 13, 467—474).—The following camphoranilic acids are prepared by condensation of the anhydride and amine,  $[\alpha]$  given being in MeOH and  $COMe_2$ , respectively: o-, m.p. 171° (decomp. from 165°),  $[\alpha]_D +50.6^\circ$ ,  $+45.3^\circ$ , and p-ethyl-, m.p. 202—203°,  $[\alpha]_D +59.2^\circ$ ,  $+47.9^\circ$ , m-, m.p. 189—190°,  $[\alpha]_D +36.9^\circ$ ,  $+30.9^\circ$ , and p-aceto-, m.p. 224—225°,  $[\alpha]_D +67.5^\circ$ ,  $+67.7^\circ$ , m-, m.p. 210°,  $[\alpha]_D +43.2^\circ$ ,  $+34^\circ$ , and p-nitro-, m.p. 200—203°,  $[\alpha]_D +75.6^\circ$ ,  $+71.2^\circ$ , m.p. 197°,  $[\alpha]_D +52.4^\circ$ ,  $+40.5^\circ$ , and p-fluoro-, m.p. 197°,  $[\alpha]_D +42.7^\circ$ ,  $+41^\circ$ . The following are obtained by nitration: camphor-2'-nitro-4'-ethyl-, m.p. 140.5°,  $[\alpha]_D -62.1^\circ$ ,  $-72.9^\circ$ , 3'-fluoro-2'-nitro-, m.p. 131—132°,  $[\alpha]_D -14.4^\circ$ ,  $-25^\circ$ , 4'-fluoro-2'-nitro-, m.p.

171°,  $[\alpha]_D -45^\circ$ ,  $-49.6^\circ$ , and -2'-nitro-4'-aceto-anilic acid, m.p. 202—203°,  $[\alpha]_D +51.8^\circ$ ,  $+44.4^\circ$ . Camphor-o-, m.p. 132—133°,  $[\alpha]_D +19.6^\circ$ ,  $+19.7^\circ$ , and -p-ethylphenylimide, m.p. 123°,  $[\alpha]_D +15.9^\circ$ ,  $+14.5^\circ$ , are obtained by condensation. m-, m.p. 196—197°,  $[\alpha]_D +46.3^\circ$ ,  $+41.7^\circ$  (Ac derivative, m.p. 220—221°,  $[\alpha]_D +25^\circ$ ,  $+23^\circ$ ), and p-Aminocamphoranilic acid, m.p. 220—221°,  $[\alpha]_D +57.5^\circ$ ,  $+53.1^\circ$  [Ac derivative, m.p. 234—235° (decomp. from 231—232°),  $[\alpha]_D +51.1^\circ$ ,  $+48.6^\circ$ ], are obtained from the  $\text{NO}_2$ -acids by  $\text{Fe}(\text{OH})_2$ . R. S. C.

**Ring-isomerisation in the camphene series.** P. LIPP, H. DESSAUER, and E. WOLF (Annalen, 1936, 525, 271—291).— $\omega$ -Aminoisocamphane (I) with  $\text{HNO}_3$  gives a complex mixture by ring changes. Reduction of  $\omega$ -nitrocamphene (II) by  $\text{Zn}-\text{AcOH}$ , followed by hydrolysis, gives 59% of camphenolaldehyde. Camphenilanamide, m.p. 170—171°, with  $\text{P}_2\text{O}_5$  gives camphenilanonitrile, b.p. 103—105°/12 mm. reduced by  $\text{Na}-\text{EtOH}$  to (I) [hydrochloride, decomp.  $>250^\circ$ , sublimes unchanged in vac.; platinichloride; phenylcarbamide, m.p. 158° (corr.), and -thiocarbamide, m.p. 148° (corr.), and Bz derivative (III), m.p. 130—132°]. With  $\text{Na}-\text{EtOH}$  (II) affords much (I), diisocamphylamine, b.p. 163°/0.13 mm., m.p. 115° [hydrochloride, m.p. 250° (decomp.); platinichloride; oxalate; perchlorate, m.p. 250° (decomp.); NO-, m.p. 160° (decomp.), and phenylcarbamide derivative, m.p. 150—151° (corr.)], camphenilone, and a mixture of camphenyl alcohols (oxidised to the aldehyde). (I) and  $\text{HNO}_3$  give endocamphene (oxidised by  $\text{KMnO}_4$  to camphenecamphoric acid, m.p. 134.4—134.8°), a mixture of R-homocamphenilols [oxidised to the ketone; p-nitrobenzoates (probably impure), m.p. 136—137° (corr.), and 89—91°; with  $\text{ZnCl}_2-\text{C}_6\text{H}_6$  gives endocamphene], and N-nitrosoisocamphylethylamine (IV), b.p. 130—134°/0.8 mm. (IV) with hot fuming  $\text{HCl}$  gives isocamphylethylamine (V), b.p. 109° (corr.)/12 mm. [hydrochloride, m.p.  $>300^\circ$ ; sublimes at about 400° (decomp.); hydrobromide; phenyl-, m.p. 122—122.5°, and naphthyl-carbamide, m.p. 151°, and Bz derivative, b.p. 181—183°/0.1 mm.]; this with  $\text{MeI}$  etc. affords isocamphylidimethylethylammonium perchlorate, cryst., the base from which at 200—250° gives  $\text{MeOH}$  and isocamphylmethylethylamine (hydrochloride, decomp. 245°; perchlorate, decomp. 255°); the Bz derivative with  $\text{PCl}_5$  gives (III). Camphenyl bromide (prep. by  $\text{PBr}_3$ ), b.p. 99—101°/13 mm., with  $\text{NH}_2\text{Et}$  at 100° affords (IV).

R. S. C.

**Steric course of addition and substitution reactions.** VI. *exo*-Additions of catalytically activated hydrogen to the dicyclo-[1:2:2]-heptene ethylenic linking. Configurations of the norborneols and norbornylamines. K. ALDER and G. STEIN [with S. SCHNEIDER, (FRL.) M. LIEB-MANN, (FRL.) E. ROLLAND, and G. SCHULZE]. VII. Catalytic reduction of ketones and ketoximes of the camphor, fenchone, and isofenchone series. K. ALDER and G. STEIN [with H. F. RICKERT]. VIII. *endo-exo*-Isomerism. II. K. ALDER and G. STEIN [with (FRL.) E. ROLLAND] (Annalen, 1936 525, 183—221, 221—247, 247—258; cf. A., 1935, 219, 349).—VI. Catalytic hydrogenation under varied

conditions of dicyclo-[1:2:2]-heptenes results preponderatingly in *cis-exo*-addition of  $\text{H}_2$  giving substances of type (A). Addition of  $\text{H}_2$  catalytically to dicyclo-[1:2:2]-heptanes containing semicyclic  $\text{CO}$ ,  $\text{C}\equiv\text{C}$ , or  $\text{C}\equiv\text{N}\cdot\text{OH}$  also occurs in the *exo*-position to give compounds having one R in the *endo*-position as in (A). Constitutions are rigidly proved. The above rules may also be applied to dicycloheptenes similar to those investigated, but containing in addition two identical substituents on the same C. It follows that the isolated Me of isocamphane is *endo*, that  $\alpha$ -norborneol has an *endo*-OH, that reaction of  $\alpha$ -norbornylamine with  $\text{HNO}_3$  occurs with, and that of the  $\beta$ -amine without, Walden inversion. From the point of view of Skita's rule the dicyclo-[1:2:2]-heptane system behaves as a substituted cyclopentane ring. Hydrogenation ( $\text{PtO}_2$ ) of 3:6-endomethylene- $\Delta^{1,4}$ -dihydrophthalic acid in  $\text{AcOH}$  gives 3:6-endomethylenehexahydro-*cis-endo*-phthalic acid (A;  $\text{R}=\text{CO}_2\text{H}$ ), m.p. 165°, and a trace of the *trans*-acid, m.p. 94°; hydrogenation of

the  $\text{Me}_2$  ester in  $\text{AcOH}$  or  $\text{MeOH}$  gives only the *cis-endo*-ester, m.p. 55°, also obtained as sole product ( $\text{PtO}_2-\text{AcOH}$ ) from  $\text{Me}_2$  3:6-endomethylene- $\Delta^1$ -tetrahydrophthalate.  $\text{CH}_3\cdot\text{C}\equiv\text{CO}_2\text{H}$  (modified prep.) and cyclopentadiene give 2:5-endomethylene- $\Delta^{1,3}$ -dihydrobenzoic acid, m.p. 93—94°, hydrogenated (colloidal  $\text{Pt}-\text{AcOH}-\text{HCl}$ ,  $\text{PtO}_2-\text{AcOH}$ ,  $\text{PtO}_2-\text{MeOH}$ , or colloidal  $\text{Pd}-\text{H}_2\text{O}$ ) to 3:5-endomethylenehexahydrobenzoic acid, m.p. 65—66°. The lactone (I) with hot  $\text{KOH}-\text{MeOH}$  gives by hydrolysis, loss of  $\text{HBr}$ , and ketonisation 3:6-endomethylene-4-ketohexahydrophthalic acid (II) (1- $\text{CO}_2\text{H}$  *exo*, 2- $\text{CO}_2\text{H}$  *endo*), m.p.

186° [ $\text{Me}_2$  ester, b.p. 167—169°/11 mm. (oxime, m.p. 136°; semicarbazone, m.p. 186°)]; this with  $\text{Ac}_2\text{O}$  gives the monoacetate, m.p. 118° (decomp.), of the ketone hydrate, which at 120—150° loses  $\text{AcOH}$  and regenerates the acid and with  $\text{CH}_2\text{N}_2$  gives the *Me* ester lactone acetate (III), m.p. 103°. Hydrogenation (Skita or Adams;  $\text{AcOH}$ ) of (II) gives the lactonic acid (IV), m.p. 134° [as (I) but with  $\text{H}$  in place of  $\text{Br}$ ]. At 250—260°/vac. (II) gives 3:6-endomethylene-4-ketohexahydro-*cis-exo*-phthalic anhydride, m.p. 171—175° (loss of  $\text{H}_2\text{O}$ ) (Ac derivative, m.p. 108°), converted into (IV) by hydrolysis ( $\text{NaOMe}$ ) and methylation. The oxime, m.p. 227° (decomp.), of (II) with  $\text{H}_2$ -colloidal  $\text{Pt}$  or  $\text{H}_2$ - $\text{PtO}_2$  in  $\text{AcOH}$  gives the lactam (V), m.p. 192° (*Me* ester, m.p. 104—105°), converted by crystallisation from  $\text{MeOH}$  into an isomeric form, m.p. 209°, which slowly reverts to (V) when crystallised from  $\text{EtOAc}$ . Nor-

camphoroxime, b.p. 114—116°/12 mm., with  $\text{H}_2$ - $\text{PtO}_2$  (40—50°; 3 atm.) or  $\text{H}_2$ -colloidal  $\text{Pd}$  at 40—50° gives norbornylendoamine (hydrochloride, m.p. 295°; picrate, m.p. 179—180°) with a little dinorbornylendoamine (picrate, m.p. 193°) and dinorbornylendo-

ethylamine (picrate, m.p. 249°; obtained by reduction of a little Ac derivative formed by the solvent); with Na-EtOH much bornyl-*endo*- and a little -*exo*-amine are formed.

[BODE]. *d* and *n* of the *endo*-forms are > those of the *exo*-forms of monocarboxylic acids, but both have about the same  $[M]$ . *d* and *n* of the *cis*-forms of the dicarboxylic acids are > those of the *trans*-forms, but  $[M]$  are about the same.

VIII. Hydrogenation of ketones and ketoximes of the camphor, fenchone, and isofenchone series is highly selective, but owing to the *as*-substitution the above rules of configuration cannot be applied. *d*-(—)-Camphoroxime gives colloidal Pt-AcOH at 50°/3 atm., or PtO<sub>2</sub> almost entirely *d*-(—)-neobornylamine, m.p. 184° (carbamide derivative, m.p. 109°). 2:5-Diketocamphane gives (PtO<sub>2</sub>; AcOH; 50°/3 atm.) a 2:5-dihydroxycamphane, m.p. 263°; its dioxime, m.p. 168—170°,  $[\alpha]_D^{25} +60.5^\circ$  in MeOH (a small amount of isomeric dioxime, m.p. 236°,  $[\alpha]_D^{25} +30^\circ$  in MeOH, is also formed), gives 2:5-diaminocamphane (dihydrochloride and diplatnichloride, m.p. 320°; dicarbamide, m.p. 192—193°, and Ac<sub>2</sub> derivative, m.p. 229—230°). *d*-Fenchoneoxime gives *d*-fenchylamine (hydrochloride, m.p. 293°; picrate, m.p. 199°; carbamide derivative, m.p. 167°). *dl*-iso-Fenchone (VI) gives *dl*- $\beta$ -isofenchol, b.p. 89°/15 mm. [*H* phthalate, m.p. 104—105°; phenylurethane, m.p. 101°; oxidised to (VI)], and a trace of the known *dl*-fenchol, now termed  $\alpha$ -fenchol; with Na-EtOH a mixture of  $\alpha$ - and  $\beta$ -forms is obtained; the  $\beta$ - is converted into the  $\alpha$ -form by hot Na-PhMe, but the  $\alpha$ -form is stable. *dl*-iso-Fenchoneoxime affords *dl*-isofenchylamine (hydrochloride, m.p. 285°; picrate, m.p. 303—304°), converted by HNO<sub>2</sub> into a mixture including probably some  $\beta$ -fenchene hydrate. (VI) and SeO<sub>2</sub> give 1:2-diketo-3:5:5-trimethyl-3:6-endomethylenecyclohexane ("isofenchonequinone"), m.p. 49—50°.

VIII. Semicarbazones, m.p. 165° and 166—167°, of 2:5-endomethylene- $\Delta^3$ -tetra- and -hexa-hydroendobenzaldehyde (VII), respectively, are obtained (cf. lit.). (VII) gives an enol acetate (VIII) and diacetate, b.p. 136—137°/13 mm. [hydrolysed to (VII) by HCl-MeOH]. Hydrolysis of (VIII) gives mainly 2:5-endomethylenehexahydroexobenzaldehyde (IX), b.p. 66—68°/12 mm. (semicarbazone, m.p. 178°), oxidised by O<sub>2</sub>-MnO<sub>2</sub> to the *exo*-acid. Hydrogenation (PtO<sub>2</sub>) of (VII) in EtOH gives 2:5-endomethylenehexahydrobenzyl endoalcohol, b.p. 93—95°/14 mm. (phenylurethane, m.p. 134°; *H* phthalate, m.p. 111°), and (IX) gives the corresponding exoalcohol, b.p. 89—90°/11 mm. (phenylurethane, m.p. 118°; *H* phthalate, m.p. 102—103°), also obtained by similar hydrogenation and subsequent hydrolysis of (VIII).

R. S. C.

Resins. I. German pine turpentine from *Pinus silvestris*, L. H. WIENHAUS H. RITTER, and W. SANDERMANN. II. Additive capacity of the pine resin acids. H. WIENHAUS and W. SANDERMANN (Ber., 1936, 69, [B], 2198—2202, 2202—2206). —I. Fresh pine turpentine appears to contain 64.2% of resin acids C<sub>20</sub>H<sub>30</sub>O<sub>2</sub> and 35.8% of neutral substances. Its treatment with steam under ordinary conditions and at >50°/30—40 mm. is described.

Repeated crystallisation of the crude acids from MeOH leads to the isolation of a small proportion of sylvic acid (I), m.p. 168—171°,  $[\alpha]_D^{25} -105.33^\circ$ , also obtained by their isomerisation by HCl in AcOH at 100°. Distillation of them under reduced pressure is accompanied by marked fall in  $[\alpha]_D$ . Treatment of the crude acids with COMe<sub>3</sub> gives a product, m.p. 139—142°,  $[\alpha]_D^{25} -112.0^\circ$ . The ultra-violet absorption spectrum of (I) indicates the presence of a conjugation of ethylenic linkings.

II. The action of maleic anhydride on the primary resin acids (II) of *P. silvestris*, L., occurs at room temp. with marked evolution of heat, and the product is completely identical in cryst. form and m.p. with that obtained from (I) by prolonged heating under pressure. Isomerisation of (II) to (I) does not therefore precede addition. Whereas (I) does not combine with *p*-O<sub>2</sub>C<sub>6</sub>H<sub>4</sub>O at <100°, (II) readily affords the yellow compound (III), C<sub>26</sub>H<sub>34</sub>O<sub>4</sub>, m.p. 214° (corr.),  $[\alpha]_D^{25} -148^\circ$  in CHCl<sub>3</sub>, which contains one ethylenic linking and is reduced (Zn dust in boiling AcOH or Pt in EtOH) to the colourless substance, C<sub>26</sub>H<sub>36</sub>O<sub>4</sub>, m.p. 184°. (III) and NH<sub>2</sub>Ph in boiling AcOH yield the amorphous product, C<sub>32</sub>H<sub>41</sub>O<sub>4</sub>N, m.p. 130—140°. With CH<sub>3</sub>N<sub>3</sub> in Et<sub>2</sub>O esterification of (III) and addition of CH<sub>3</sub>N<sub>3</sub> leads to the compound, C<sub>28</sub>H<sub>38</sub>O<sub>4</sub>N<sub>2</sub>, m.p. about 250°, isomerised by Ac<sub>2</sub>O at room temp. to the colourless substance, m.p. 270°. Irradiation of (III) in EtOH with ultra-violet light or exposure of its solution in EtOH containing eosin in sunlight leads to a substance, m.p. 196°, transformed by CH<sub>3</sub>N<sub>3</sub> into the Me<sub>2</sub> ester, C<sub>26</sub>H<sub>34</sub>O<sub>5</sub>(OMe)<sub>2</sub>, m.p. 241°. (II) and  $\alpha$ -naphthaquinone in MeOH yield the corresponding acid, m.p. 185° [Me ester, C<sub>26</sub>H<sub>30</sub>O<sub>5</sub>C<sub>10</sub>H<sub>6</sub>O<sub>2</sub>(OMe), m.p. 195°], reduced (Zn in AcOH or H<sub>2</sub>-Pt in EtOH) to the H<sub>2</sub>-compound, C<sub>26</sub>H<sub>30</sub>O<sub>2</sub>C<sub>10</sub>H<sub>6</sub>O<sub>2</sub>, m.p. 265°. *p*-Xyloquinone is not added to (II) and at a higher temp. dehydrogenates with production of *p*-xyloquinol. *d*-Pimaric acid present in (II) and distinguished by its stability and the dextrorotatory labile acid of pine resin do not react with quinones. A volumetric determination of the levorotatory labile acid in turpentine is thus indicated.

H. W.

Resin components of ammoniacum. II. Constitution of ammosesin. K. KUNZ and L. HOOPS (Ber., 1936, 69, [B], 2174—2182; cf. A., 1935, 219).—Treatment of diacetylammomesin (I) in EtOAc at -20° with 1.5% O<sub>3</sub> leads directly to the aldehyde (II), C<sub>15</sub>H<sub>12</sub>O<sub>7</sub>, m.p. 137° [*p*-nitrophenylhydrazine, m.p. 194° (decomp.)], in 80—90% yield. Oxidation of (II) with 8% O<sub>3</sub> in EtOAc at -20° yields the corresponding acid (III), m.p. 205° (decomp.)

after darkening at 150° and softening at 165°. When heated for a short time with MeOH or EtOH or at 140—170°/vac. (III) passes into the lactone (IV), m.p. 208° after becoming discoloured at 200°, trans-

formed with loss of Ac by boiling  $2N\text{-Na}_2\text{CO}_3$  into the acid,  $\text{C}_{11}\text{H}_8\text{O}_6$ , m.p.  $233^\circ$  after becoming discoloured at  $210^\circ$ , and converted by boiling MeOH into the compound,  $\text{C}_{12}\text{H}_{10}\text{O}_6$ , m.p.  $158\text{--}5^\circ$  (corresponding *Et* derivative, m.p.  $152\text{--}5^\circ$ ). Oxidation of (IV) with  $\text{KMnO}_4$  in  $\text{COMe}_2$  affords 4-acetyl- $\beta$ -resorcylic acid, m.p.  $151^\circ$ . Treatment of (III) with  $\text{KOH-H}_2\text{O}$  at  $180^\circ$  leads to  $\beta$ :2:4-dihydroxybenzoylpropionic acid, m.p.  $199\text{--}200^\circ$  (corresponding *Me*-acid, m.p.  $147^\circ$ ). Oxidation of (I) with  $\text{CrO}_3$  in AcOH at room temp. gives  $\text{COMe}_2$ . The material remaining after removal of (II) from the products of the ozonolysis of (I) is distilled with steam, thereby yielding  $\text{COMe}_2$  and giving laevulaldehydedi-*p*-nitrophenylhydrazon, m.p.  $176^\circ$ , and a substance,  $\text{C}_{17}\text{H}_{18}\text{O}_4\text{N}_6$ , m.p.  $187^\circ$

after darkening at  $175^\circ$ , also obtained from synthetic laevulaldehyde. The structure A for ammoresinol is therefore confirmed. H. W.

**isoChavicol acid.** H. LONHAUS (Annalen, 1936, 525, 312—315).—*isoChavicol* acid is obtained in 25% yield with m.p.  $134\text{--}136^\circ$  from Me  $\gamma$ -bromo*iso*-chavicate (dimorphic). It or *isopiperic* acid with I in  $\text{C}_6\text{H}_6$  or MeOH in light gives piperic acid. The oily Me ester is shown by illumination to be at least 75% pure. R. S. C.

**Dehydrogenation of ursolic acid by selenium.** N. L. DRAKE and H. M. DUVAL (J. Amer. Chem. Soc., 1936, 58, 1687—1688; cf. Ruzicka *et al.*, A., 1932, 517).—Ursolic acid is dehydrogenated (Se at  $320\text{--}340^\circ$ ) to 1:2:7- $\text{C}_{10}\text{H}_5\text{Me}_3$ , 2:7- $\text{C}_{10}\text{H}_5\text{Me}_3$ , and the picene hydrocarbon,  $\text{C}_{25}\text{H}_{40}$  (?  $\text{C}_{25}\text{H}_{48}$ ) of Ruzicka *et al.* (cf. *loc. cit.*; A., 1934, 530). H. B.

**Cerin and friedelin.** III. Oxidative degradation of friedelin. N. L. DRAKE and W. P. CAMPBELL. IV. Dehydrogenation of friedelinol. N. L. DRAKE and W. T. HASKINS (J. Amer. Chem. Soc., 1936, 58, 1681—1684, 1684—1687; cf. A., 1935, 1373, 1502).—III. Friedelin (I) is reduced (Na, amyl alcohol) to friedelinol,  $\text{C}_{30}\text{H}_{51}\text{OH}$ , m.p.  $301\text{--}304^\circ$  [iodide, m.p.  $224\text{--}226^\circ$  (decomp.); acetate, m.p.  $315\text{--}316^\circ$ ; Me ether, m.p.  $265\text{--}267^\circ$ ], the benzoate, m.p.  $250\text{--}251^\circ$ , of which decomposes at  $280\text{--}320^\circ$  in  $\text{N}_2$  to BzOH and friedelene (II),  $\text{C}_{30}\text{H}_{50}$ , m.p.  $257\text{--}258^\circ$ . (I) and  $\text{MgPhBr}$  give a little phenylfriedelene, m.p.  $269\text{--}271^\circ$ ;  $\text{MgMeI}$  affords methylfriedelinol (III), m.p.  $316\text{--}319^\circ$ , and some methylfriedelene, m.p.  $272\text{--}274^\circ$  [also obtained by dehydrogenation ( $\text{Ac}_2\text{O}$ -xylene) of (III)]. (II) is oxidised ( $\text{CrO}_3$ , AcOH) to the unsaturated ketone friedelenone, m.p.  $290\text{--}291^\circ$ , and amorphous acidic material [reduction (Na,  $\text{Pr}^\circ\text{OH}$ ) of which gives a little (IV) (below)]. (I) is similarly oxidised to a mixture (A) of friedonic acid,  $\text{C}_{28}\text{H}_{49}(\text{CO})\text{CO}_2\text{H}$ , m.p.  $206\text{--}207^\circ$  (Me ester, m.p.  $249\text{--}251^\circ$ ), and norfriedonic acid (not isolable); reduction (Na- $\text{Pr}^\circ\text{OH}$ ) of (A) affords friedololactone,  $\text{C}_{30}\text{H}_{50}\text{O}_2$ , m.p.  $309\text{--}312^\circ$ , and norfriedololactone (IV), m.p.  $289\text{--}291^\circ$ . (I) thus contains the  $>\text{CH}\cdot\text{CO}\cdot\text{CH}_2\cdot$  grouping.

IV. Dehydrogenation (Se at  $315\text{--}325^\circ$ ) of friedelinol (V) gives 1:2:7- $\text{C}_{10}\text{H}_5\text{Me}_3$ , 1:2:8-trimethylphenanthrene, an alkylcyclohexene,  $\text{C}_{11}\text{H}_{20}$ , b.p.  $180\text{--}185^\circ$  [further dehydrogenation by Se at  $320^\circ$  (sealed tube) to a product, b.p.  $187\text{--}192^\circ$  (brominated to a compound, m.p.  $169\text{--}175^\circ$ )], and the picene hydrocarbon,  $\text{C}_{25}\text{H}_{40}$  ((?  $\text{C}_{25}\text{H}_{48}$ ), m.p.  $305\text{--}306^\circ$ , of Ruzicka *et al.* (A., 1934, 530). The annexed structure is assigned to (V). H. B.

**Sapogenins.** I. Sapogenins of sarsaparilla root. F. A. ASKEW, S. N. FARMER, and G. A. R. KON (J.C.S., 1936, 1399—1403).—*Smilagenin* (I), m.p.  $183\text{--}184^\circ$ ,  $[\alpha]_D^{25} -69^\circ$  in  $\text{CHCl}_3$ , has been isolated from Jamaican sarsaparilla root, and forms an acetate, m.p.  $150\text{--}151^\circ$ ,  $[\alpha]_D^{25} -59\cdot6^\circ$  in  $\text{CHCl}_3$ , and a benzoate, m.p.  $181\text{--}181\cdot5^\circ$ . (I) is converted by  $\text{H}_2\text{CrO}_4$  into *smilagenone*, m.p.  $156\text{--}157^\circ$ , and by  $\text{PCl}_5$  into *smilagenyl chloride*, m.p.  $194\text{--}195^\circ$ , and by reduction ( $\text{Na-C}_5\text{H}_{11}\text{OH}$ ) into *deoxysmilagenin*, m.p.  $132\text{--}133^\circ$ . Surface film measurements of the three *Digitalis* sapogenins, sarsapogenin (II), and (I) show that the formulae for tigogenin and gitogenin are confirmed, but make it necessary to revise the formula for (II), which is closely related to (I). F. R. S.

**Constitution of papaveristerol.** E. BURES and S. FUCIK (Časopis českoslov. Lék., 1935, 15, 159—167; Chem. Zentr., 1935, ii, 3926).—*Papaveristerol* (I),  $\text{C}_{30}\text{H}_{50}\text{O}$ , m.p.  $134\text{--}134\cdot5^\circ$ ,  $[\alpha]_D^{25} -39\cdot88^\circ$  in  $\text{CHCl}_3$  (acetate, m.p.  $122^\circ$ ; dibromide acetate, m.p.  $108\text{--}109^\circ$ ), is isolated from poppy-seed oil soap. (I) is reduced ( $\text{Na-C}_5\text{H}_{11}\text{OH}$ ) to *dihydropapaveristerol*, m.p.  $128^\circ$  (acetate, m.p.  $115^\circ$ ), and oxidised by  $\text{CuO}$  at  $285\text{--}300^\circ$  to *papaveristenone*,  $\text{C}_{30}\text{H}_{48}\text{O}$ , m.p.  $125\cdot5\text{--}126^\circ$  (semicarbazone, m.p.  $102^\circ$ ; oxime, m.p.  $85^\circ$ ); the latter is further oxidised ( $\text{KMnO}_4$ ) to a keto-acid, which is then reduced (Clemmensen) to an acid,  $\text{C}_{29}\text{H}_{48}\text{O}_2$ , m.p.  $101\text{--}102^\circ$ . The partial formula  $\text{C}_{26}\text{H}_{43}(\text{CH}_2\cdot\text{CH}\cdot\text{OH})(\text{CH}\cdot\text{CH}_2)$  is ascribed to (I). H. N. R.

**Constitution of Hseh Tsuang seed.**—See this vol., 1435.

**Dragon's blood.**—See this vol., 1435.

**Oximation.** K. C. GULATI and J. N. RAY (Current Sci., 1936, 5, 75).—Flavone and  $\alpha$ -naphthylflavone when boiled with  $\text{NH}_2\text{OH}\cdot\text{HCl}$  in aq.  $\text{C}_5\text{H}_5\text{N}$  afford oximes, m.p.  $237^\circ$  and  $181^\circ$ , respectively. This method is used successfully in difficult cases. J. L. D.

**Styrylpyrylium salts.** XVII. Colour phenomena associated with 4-phenylbenzo- $\beta$ -naphthaspiropyran and 4-phenyl- $\alpha\beta$ -dinaphthaspiropyran. I. M. HEILBRON, D. H. HEY, and A. LOWE (J.C.S., 1936, 1380—1383).—2-Ethylchromone and  $\text{MgPhBr}$  give 4-phenyl-2-ethylbenzopyrylium chloride, which with 2:1- $\text{OH}\cdot\text{C}_{10}\text{H}_6\cdot\text{CHO}$ , followed by hydrolysis, affords 4-phenyl-3'-methylbenzo- $\beta$ -naphthaspiropyran, m.p.  $219\text{--}220^\circ$ . 7-Methoxy-4-phenyl-3'-methylbenzo- $\beta$ -, m.p.  $256\text{--}258^\circ$ , 4-phenyl-3'-methyl- $\alpha\beta$ -di-, m.p.  $207\text{--}208^\circ$ , and 4-phenyl-3:3'-dimethyl-

$\alpha\beta$ -di-naphthaspiropyran are similarly prepared. These substances do not develop colour in boiling inert solvents and the anomalies found by Heilbron *et al.* (A., 1933, 614) no longer exist. F. R. S.

**Pigments of cotton flowers. III. Karunganni (*Gossypium indicum*).** K. NEELAKANTAM and T. R. SESHADRI (Proc. Indian Acad. Sci., 1936, 4, A, 54—58).—From the petals of Karunganni, *gossypin*, m.p. 230° (decomp.), hydrolysed to gossypetin and glucose, a non-glycosidic substance,  $C_{16}H_{12}O_7$ , m.p. 255—257° (Ac derivative, m.p. 186—187°), quercetin, herbacitrin, and gossypitrin have been isolated. F. R. S.

**Benzoxanthones. II.** W. KNAPP (J. pr. Chem., 1936, [ii], 146, 113—118; cf. A., 1935, 1247).—*Salicylic acid 1-C<sub>10</sub>H<sub>7</sub> ether* (o-1-naphthoxybenzoic acid; from  $C_{10}H_7\cdot OH$ , o- $C_6H_4Cl\cdot CO_2K$ , NaOMe, and Cu at 150—200°, m.p. 134—136°, is stable to  $Ac_2O$ , but with  $P_2O_5$  in hot  $C_6H_6$  gives 3:4-benzoxanthone, m.p. 162° (corr.) (lit. 155°). Similar prep. of o- $CO_2H\cdot C_6H_4\cdot O\cdot C_{10}H_7\cdot 2$  (I) gives also 10% of naphtha-1':2':2':1-benzofuran, m.p. 162° (lit. 296°). (I) is stable to  $Ac_2O$ , but with  $P_2O_5$  gives 1:2-benzoxanthone, m.p. 145° (corr.) (lit. 140°, 142°). o- $OPh\cdot C_6H_4\cdot CO_2H$ , m.p. 114°, similarly prepared, gives with  $P_2O_5$  xanthone, m.p. 177° (corr.) (cf. lit.); with  $Ac_2O$  it probably gives a mixed anhydride, since xanthone is obtained only after distillation.

R. S. C.

**Alkylacetylenes and their additive products. XIV. Synthesis of dioxolan derivatives from alkylacetylenes.** D. B. KILLIAN, G. F. HENNION, and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 1658—1659; cf. A., 1934, 759).— $CH\cdot C\equiv Bu$  (I) with  $(\cdot CH_2\cdot OH)_2$  and  $CH_2Cl\cdot CH(OH)\cdot CH_2\cdot OH$  in presence of  $CCl_3\cdot CO_2H$  and a catalyst (from  $BF_3$ ,  $Et_2O$ , red  $HgO$ , and  $MeOH$ ) gives 2-methyl-, b.p. 62—63°/20 mm., and 2-methyl-4-chloromethyl-, b.p. 109°/25 mm., -2-butyl-1:3-dioxolan, respectively. Similarly, (I) with  $OH\cdot CHPh\cdot CO_2H$  and  $OH\cdot CMe_2\cdot CO_2H$  affords 4-keto-5-phenyl-2-methyl-, b.p. 136—138°/19 mm., m.p. 44—45°, and 4-keto-2:5:5-trimethyl-, b.p. 104°/25 mm., -2-butyl-1:3-dioxolan, respectively, whilst Me tartrate yields Me 2-methyl-2-butyl-1:3-dioxolan-4:5-dicarboxylate, b.p. 141—142°/9 mm. Mannitol and (I) give the dioxolan,  $\begin{matrix} CHR\cdot O \\ CHR\cdot O \end{matrix} > CMeBu$  ( $R = \begin{matrix} CH_2\cdot O \\ CH\cdot O \end{matrix} > CMeBu$ ), b.p. 210—212°/9 mm.  $CH_2\cdot CH\cdot C\equiv CH$  and  $(\cdot CH_2\cdot OH)_2$  similarly afford 2-methyl-2- $\beta$ - $\beta'$ -hydroxyethoxyethyl-1:3-dioxolan, b.p. 140—142°/20 mm., and the dioxolan,  $\begin{pmatrix} CH_2\cdot O \\ CH_2\cdot O \end{pmatrix} > CMe\cdot CH_2\cdot CH_2\cdot O\cdot CH_2\cdot$ , b.p. 204—206°/20 mm.

H. B.

**Natural coumarins. XX. Constitution of nodakenin from *Peucedanum decursivum*, Maxim.** E. SPATH and P. KATNRATH (Ber., 1936, 69, [B], 2062—2066; cf. Arima, A., 1927, 599; 1929, 430, 914).—Prolonged extraction of the dry roots with pure MeOH at about 300 mm., evaporation of the extract, and treatment of the residue with  $H_2O$  yields nodakenin (I), m.p. 218—219° (decomp.), hydrolysed by 3%  $H_2SO_4$  to glucose and nodakenetin (II),  $C_{14}H_{14}O_4$ , m.p. 192°,  $[\alpha]_D^{24} -25.4^\circ$  in  $CHCl_3$ .

(II) is unaffected by distillation at 280°(bath)/14 mm. or by heating with  $Al_2O_3$  at 260°/vac. but is converted by distillation with  $P_2O_5$  at 120—150°(bath)/1 mm. smoothly into anhydronodakenetin (III),  $C_{14}H_{10}O_3$ , m.p. 138—139°,  $[\alpha]_D \pm 0^\circ$  in  $CHCl_3$ . Catalytic hydrogenation (Pd-sponge in AcOH) of (III) gives deoxydihydro-oreoselone, m.p. 115—117°. This observation combined with the difficulty of dehydration

of (II) leads to the structure C for (I) and, combined with the optical inactivity, to the structure A or B for (III). H. W.

**Tannin of Formosan tea leaves.** Y. OSHIMA (Bull. Agric. Chem. Soc. Japan, 1936, 12, 103—114, and Proc. Imp. Acad. Tokyo, 1936, 12, 189—190).—Extraction of fresh tea leaves with  $H_2O$  gave gallic acid, an amorphous tannin,  $C_{30}H_{24}O_{14}$ , l-epicatechin [identical with that obtained by Freudenberg (A., 1923, i, 697)], and a gallocatechin (I),  $C_{15}H_{14}O_7$ , m.p. 227°,  $[\alpha]_D -37.5^\circ$  in  $H_2O$ ,  $-67.0^\circ$  in EtOH (pentacetate, m.p. 189°,  $[\alpha]_D -21.3^\circ$  in  $COMe_3$ ;  $Me_5$  derivative, m.p. 184°,  $[\alpha]_D -15.2^\circ$  in  $COMe_3$ ). The amorphous tannin is bis-(5:7:3':4':5'-pentahydroxy)-flavpinacol, proved by its synthesis from phloracetophenone triacetate and gallaldehyde triacetate, hydrolysis of the product to the chalcone,  $C_{15}H_{12}O_7$ , m.p. 278°, and reduction of the latter to the tannin by Zn and AcOH. Reduction of the  $Me_5$  derivative of (I) with Na and EtOH gave  $\alpha$ -2:4:6-trimethoxyphenyl- $\gamma$ -3:4:5-trimethoxyphenylpropane, m.p. 91°, which was synthesised by catalytic reduction of the condensation product of  $\omega$ -acetoxy-3:4:5-trimethylgallacetophenone with phloroglucinaldehyde  $Me_3$  ether. (I) was synthesised by catalytic reduction of delphinidin  $Me_5$  ether. J. N. A.

**Thioindigo syntheses. I. Synthesis of 6:6'-dichloro-4:4'-dimethylthioindigo and 6:6'-dichloro-4:4'-dimethoxythioindigo.** R. SHIBATA and T. NISHI. II. Bromination of 6:6'-dichloro-4:4'-dimethylthioindigo, 6:6'-dichloro-4:4'-dimethoxythioindigo, and thioindigo-red. R. SHIBATA and M. OKUYAMA. III. Condensation products of thioindigotin-7:7'-dicarboxylic acid chloride with aromatic amines. R. SHIBATA and A. SASSA (J. Soc. Chem. Ind. Japan, 1936, 39, 280—282B, 282—283B, 283—284B).—I. 3-Chloro-6-cyano-5-methylthioglycolic acid, m.p. 125°, obtained from the corresponding  $NH_2$ -acid, is hydrolysed to the 6-carboxylic acid, m.p. 132—133°, which with NaOH and S gives 6:6'-dichloro-4:4'-dimethylthioindigotin (I). The 4:4'-(OMe)<sub>2</sub>-compound (II) is similarly obtained.

II. Bromination of (I) under different conditions yields only the 5:5'- or 7:7'- $Br_2$ -derivatives, and (II)

similarly affords a  $Br_2$ -derivative. Bromination of thioindigo-red gives coloured dyes.

III. Thioindogotin-7 : 7'-dicarboxyl chloride condenses with amines to form differently coloured dyes.

F. R. S.

**Preparation of some  $\beta$ -diketopiperidines.** C. GUSTAFSSON (Finska Kem. Medd., 1936, 45, 98—103).— $\delta$ -Keto-esters containing N in the chain have been prepared, and the Dieckmann reaction has been applied to them to produce diketopiperidines.  $NHMe \cdot CH_2 \cdot CO_2Et$  and  $COMe \cdot CH_2Cl$  give *Et methylacetonylaminoacetate*, (I), b.p. 95—96°/6 mm., 105—106°/9 mm., which with MeI gives *dimethylacetonylcarbethoxymethylammonium chloride*, m.p. 131—133° (decomp.). (I) is decomposed by  $NaOEt \cdot EtOH$ , but reacts smoothly in dry  $Et_2O$ . The unstable ppt. is treated with excess of MeI and after keeping the ppt. and filtrate are treated separately with dry HCl to remove Na and yield respectively 3 : 5-diketo-1 : 1-dimethylpiperidinium chloride, pale brown, reddening at 150°, m.p. 208—209° (decomp.), and 3 : 5-diketo-1 : 1 : 4 : 4-tetramethylpiperidinium iodide, m.p. 174.5—175.5°.  $COMe \cdot CH_2 \cdot CMe_2 \cdot NH_2$  with  $ClCO_2Et(Me)$  gives *N-carbethoxydiacetonamine* (II), b.p. 105.5—107°/6 mm., and *N-carbomethoxydiacetonamine*, b.p. 100—102°/7 mm. (II) is decomposed completely by  $NaOEt$  in  $EtOH$ , but smoothly in  $Et_2O$ . Among the products is  $CHMeBu \cdot OH$ .

M. H. M. A.

**dicyclo-[1 : 2 : 2]-1-Azaheptane.** V. PRELOG and E. CERKOVNIKOV (Annalen, 1936, 525, 292—296).—*Et tetrahydropyran-4-carboxylate* with  $Na \cdot EtOH \cdot C_6H_6$  gives 33% of 4-hydroxymethyltetrahydropyran, b.p. 210—214° (*phenylurethane*, m.p. 86—87°), converted by 45%  $HBr$  at 100—110° into *ae-dibromo- $\gamma$ -bromomethylpentane*, b.p. 158—160°/10 mm., which with  $NH_3 \cdot MeOH$  at 130—140° gives 31.2% of dicyclo-[1 : 2 : 2]-1-azaheptane (I), m.p. 71° (sinters from 65°), b.p. 120—121°

(hydrochloride, hygroscopic; *platini*- and *auri-chloride*; *picrate*; *picrolonate*; *methiodide*, hygroscopic; *methoaurichloride*).

R. S. C.

**Processes of catalytic dehydrogenation. IX. Dehydrogenation of hydrogenated derivatives of 2-pyridone.** E. SPATH and F. GALINOVSKY (Ber., 1936, 69, [B], 2059—2061).—2-Ketopiperidine is dehydrogenated by prolonged heating with Pd-sponge at 260—270° to 2-pyridone in 50—60% yield. 1- and 6-Methyl-2-ketopiperidine behave similarly. Better yields are obtained in the similar dehydrogenation of hydro-carbostyryl and -isocarbostyryl and their *N*-Me derivatives.

H. W.

**Tautomerism of pyridine homologues. II. Syntheses in the pyridine series.** A. E. TSCHITSCHIBABIN (Bull. Soc. chim., 1936, [v], 3, 1607—1632; cf. A., 1927, 885).—2- and 4-Alkyl-pyridines and -quinolines are alkylated in the side-chain by  $NaNH_2$  and alkyl halides; an excess of base is used to minimise the formation of quaternary salts and olefines. The yield depends partly on the amount of Na derivative present in equilibrium with the base and  $NaNH_2$ , being greater in the case of  $\gamma$ - than of  $\alpha$ -picoline. Isomerides (? 3- or 6-derivatives) are

formed in small amounts and two alkyl groups may enter the same side-chain. The following are thus prepared in 40—80% yield : 2- and 4- $\beta$ -phenylethyl-, b.p. 164°/20 mm., 2- $\beta\beta'$ -diphenylisopropyl-, b.p. 198°/5 mm. (*picrate*, m.p. 136°), 2- $\gamma$ -phenylpropyl-, b.p. 199°/2 mm. (*picrate*, m.p. 125°), 2-*n*-amyl-, b.p. 206.5—207° [*picrate*, m.p. 73°; *platnichloride*, m.p. 160° (decomp.)]; a base (*picrate*, m.p. 164°) is also formed], 2-, b.p. 200° (*picrate*, m.p. 105°; *platnichloride*, decomp. >160°), and 4-isoamyl- b.p. 225—227° [*picrate*, m.p. 112—113°; *platnichloride*, m.p. 214° (decomp.)], 2-cyclohexylmethyl-, b.p. 118°/12 mm. (*picrate*, m.p. 135°), 2- $\Delta^2$ -butenyl-, b.p. 188—192° (*picrate*, an oil;  $HgCl_2$  compound, cryst.), 2- and 4-*n*-propyl- [*picrate*, m.p. 134° (lit. 153°); *platini*-, m.p. 210°, and *auri-chloride*, m.p. 116—118°], 4-isobutyl-, b.p. 195° (*picrate*, m.p. 122°; *platnichloride*, m.p. 216°), 4-*n*-butyl-, b.p. 229—230° [*picrate*, m.p. 102—103°; *platnichloride*, m.p. 203° (decomp.)], 2- $\beta$ -phenylethyl-6-methyl-, b.p. 165°/23 mm. [*picrate*, m.p. 125°; *platnichloride*; a base,  $C_{16}H_{13}N$ , m.p. 71—72° (*picrate*, m.p. 165°; *platnichloride*), is also obtained], 2- $\beta$ -phenylethyl-5-ethyl-, b.p. 185—195°/17 mm., 309—312°/760 mm. [*platnichloride*, m.p. 170—172° (decomp.)], 4- $\alpha$ -methylpropyl-, b.p. 187° (*picrate*, m.p. 142°), and 3-phenyl-4- $\Delta^2$ -butenyl-pyridine, b.p. 125—130°/20 mm.;  $\gamma$ -4-pyridyl- $\beta\delta$ -dimethylpentane, b.p. 208—210° (*picrate*, m.p. 115°);  $\delta$ -4-pyridyl- $\beta\zeta$ -dimethylheptane, b.p. 261° (*picrate*, m.p. 89°; *platnichloride*, m.p. 180°);  $\epsilon$ -4-pyridyl-*n*-nonane, b.p. 265—267° (*picrate*, m.p. 114—116°); 4-*n*-propyl- (*picrate*, m.p. 207°), 2- $\beta$ -phenylethyl- (impure), b.p. 225—230°/12 mm., and 2- $\beta\beta'$ -diphenylisopropyl-quinoline (*picrate*).

R. S. C.

**Manufacture of pyridine dyes.**—See B., 1936, 924.

**Introduction of the triphenylmethyl group. I.** E. FUNAKUBO and T. HIROTANI (Ber., 1936, 69, [B], 2123—2130).—Treatment of isochavibetol with  $CPh_3Cl$  in  $C_6H_5N$  at 155° yields triphenylmethylisochavibetol (I), m.p. 184—185°, isochavibetol  $CPh_3$  ether, (II), m.p. 207—209°, and a sparingly sol., unidentified material. (I) contains OH, OMe, and a double linking in the side-chain. It yields an acetate, m.p. 175.5—176°, hydrolysed to (I), a benzoate, m.p. 168—169°, a *Me* ether, m.p. 168.5—169°, and a phenylurethane, m.p. 215.8—217°. It is unaffected by KOH at 234—236°, but is transformed by HI ( $d$  1.7) at 150° into a substance, m.p. 93—96° after softening at 71°, characterised as the diacetate, m.p. 187—188°, and *Me*, derivative, m.p. 132—137°. (II) contains OMe and a double linking in the side-chain, but not OH. The yield of (I) increases at the expense of (II) when reaction is prolonged. Similarly isoeugenol,  $CPh_3Cl$ , and  $C_6H_5N$  at 150° give triphenylmethylisoeugenol, m.p. 208—209° (acetate, m.p. 150—150.5°), and isoeugenol  $CPh_3$  ether, m.p. 211—212.5°. 1-Triphenylmethylindole, m.p. 211.5—212°, is obtained from indole and  $CPh_3Cl$  in boiling  $C_6H_5N$  or from Mg indolyl iodide and  $CPh_3Cl$  in  $Et_2O$ . 1-Triphenylmethyl-2-methylindole, m.p. 215.5—216°, is obtained similarly.

H. W.

**Synthesis of 3-alkyl- and 3-aryl-quinolines.** F. L. WARREN (J.C.S., 1936, 1366—1368).— $PhNO_2$ ,  $NH_2Ph$ , and  $\beta$ -ethylglycerol  $\alpha\gamma$ - $Et_2$  ether give 3-

ethylquinoline (picrate, m.p. 196—197°).  $\beta$ -Phenylglycerol  $\alpha$ -Et<sub>2</sub> ether, b.p. 155°/21 mm., obtained from OH-CPH(CH<sub>2</sub>Cl)<sub>2</sub>, with PhNO<sub>2</sub> and NH<sub>2</sub>Ph yields 3-phenylquinoline, and with  $\alpha$ -C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub> forms 3-ethyl- $\alpha$ -naphthaquinoline, m.p. 75.5° (picrate, m.p. 188°). F. R. S.

Urethanes as local anaesthetics. III. Alkyl N-8-quinolylcarbamates. R. E. DAMSCHROEDER and R. L. SHRINER (J. Amer. Chem. Soc., 1936, 58, 1610—1612).—8-Aminoquinoline and ClCO<sub>2</sub>Alk in Et<sub>2</sub>O+aq. Na<sub>2</sub>CO<sub>3</sub> give *Me*, m.p. 61.5—62.5°, *Et*, m.p. 66—67°, *Pr*<sup>a</sup>, m.p. 58—59°, *Bu*<sup>a</sup>, m.p. 40°, *Bu* <sup>$\beta$</sup> , m.p. 69—70°, *n*- and *iso*-amyl, and *n*-hexyl, N-8-quinolylcarbamates; the hydrochlorides have m.p. 199—201°, 165—166°, 156—157°, 146—149°, 155—165°, 147—149°, 149—152°, and 145—147° (all with decomp.), respectively, and have little or no anaesthetic activity. H. B.

Derivatives of basically substituted enol and thioenol compounds.—See B., 1936, 920.

Syntheses in the hydroaromatic series. XXVI. Diene synthesis of hetero-rings containing nitrogen. II. Adducts derived from isoquinoline and acetylenedicarboxylic esters. O. DIELS and J. HARMS (Annalen, 1936, 525, 73—94).—The action of (C·CO<sub>2</sub>Me)<sub>2</sub> on isoquinoline (I) in Et<sub>2</sub>O at 0° and finally at room temp. gives "labile adduct" (II), m.p. 167—169°, and (III), m.p. 142—145°, the latter in relatively very small amount. In solubility and behaviour in ultra-violet light (II) is closely allied

to the "labile" C<sub>5</sub>H<sub>5</sub>N, quinoline, and stilbazole adducts and its position in the "labile" series is established further by its behaviour towards CH<sub>2</sub>N<sub>2</sub>. In the first phase two *mono*-adducts, (IV) and (V), result, one of which passes with excess of CH<sub>2</sub>N<sub>2</sub> into the *bis*-adduct (VI), m.p. 155—158° (decomp.), whereas the other is stable towards excess of CH<sub>2</sub>N<sub>2</sub> and ultimately passes into a substance C<sub>22</sub>H<sub>21</sub>N which

again adds CH<sub>2</sub>N<sub>2</sub> and then loses 2 N with formation of the compound (VII), m.p. 207° (accompanied by a substance, C<sub>23</sub>H<sub>23</sub>O<sub>8</sub>N, m.p. 148—150°). (VI) is converted by HCl into (I) and pyrazoledicarboxylic acid, thus establishing the position of the double linkings in the "unsaturated ester chain." The CH<sub>2</sub>N<sub>2</sub> reaction also proves that these linkings are not equiv. to one another. Hydrogenation of (II) proceeds rapidly (colloidal Pd in MeOH or PtO<sub>2</sub>

in AcOH) to a H<sub>2</sub>-derivative, m.p. 180°, which adds 2 CH<sub>2</sub>N<sub>2</sub>, and hence contains the "ester chain"

unaltered and 2 H at 3 and 4, and then very slowly to the H<sub>4</sub>-compound, m.p. 217°. Stabilisation of (II) proceeds most readily in boiling xylene and gives the compound (VIII), m.p. 231° (decomp.), also obtained similarly from (III), and an *isomeride*, m.p.

170—172°. (VIII) gives a *perbromide*, C<sub>21</sub>H<sub>18</sub>O<sub>8</sub>NBr<sub>3</sub>, decomp. 140°, a *perchlorate*, C<sub>21</sub>H<sub>18</sub>O<sub>8</sub>N·ClO<sub>4</sub>·0.5H<sub>2</sub>O, decomp. 215°, and an *indolizine substance*, C<sub>18</sub>H<sub>15</sub>O<sub>6</sub>N (IX), m.p. 153°. Treatment of (II) with excess of Br in abs. EtOH yields the *perbromide*, C<sub>18</sub>H<sub>16</sub>O<sub>6</sub>NBr<sub>3</sub>, decomp. 140°, converted by hot aq. K<sub>2</sub>CO<sub>3</sub> into the *substance*, C<sub>18</sub>H<sub>14</sub>O<sub>6</sub>NBr, m.p. 166°, and (IX). Oxidation of (II) by H<sub>2</sub>O<sub>2</sub> in AcOH followed by treatment with CH<sub>2</sub>N<sub>2</sub>, or treatment of (II) with Br in MeOH-H<sub>2</sub>O gives the ester (X) (R=Me), m.p. 152° [if Br-EtOH-H<sub>2</sub>O is used a similar ester (X; R=Et), m.p. 118—119°, results], hydrolysed and decarboxylated to 2-phenylpyridine.

In contrast with (II), (III) is very unstable and tends to decompose into its components. It adds CH<sub>2</sub>N<sub>2</sub>, but the intermediate di-adduct loses N<sub>2</sub> during the reaction and gives the *substance*, C<sub>3</sub>H<sub>23</sub>O<sub>8</sub>N<sub>3</sub>, m.p. 168—169°. During very cautious hydrogenation rupture of the mol. occurs, so that the isolable product is a dihydroisoquinoline (*picrate*, m.p. 167°). Stabilisation of (II) is not caused by acids, and the production of small amounts of (VIII) from it in boiling xylene is attributed to a preliminary fission into its components from which (II) is formed, whence (VIII).

The possibility of stabilising the labile adducts of the members of the series depends on the presence of a displaceable H attached to C vicinal to N and of the intact "ester chain." The presence of the  $\Delta^{3:1}$  double linking is not essential, since the H<sub>2</sub>-derivative of (II) passes when heated above its m.p. into a very characteristic red *isomeride*, m.p. 189°, and is oxidised by Br-MeOH-H<sub>2</sub>O to (X) and a *tribromide*, C<sub>21</sub>H<sub>20</sub>O<sub>8</sub>NBr<sub>3</sub>, pale brown needles, decomp. 138°, which slowly pass into a substance, decomp. 145°.

H. W.

Friedel-Crafts reaction in the carbazole series. II. D. R. MITCHELL and S. G. P. PLANT (J.C.S., 1936, 1295—1298).—3:6-Dibenzoylcarbazole and KOH

give carbazole-3:6-dicarboxylic acid (I) (*Et* ester, m.p. 203°); *Et* 9-methylcarbazole-3:6-dicarboxylate, m.p. 161—163°, is similarly obtained from 3:6-dibenzoyl-9-methylcarbazole, m.p. 220°. *Et* carbazole-3:6-diphthaloylate, m.p. 195° (from the corresponding acid), with KOH affords (I) and, with Me<sub>2</sub>SO<sub>4</sub>, *Et* 9-methylcarbazole-3:6-diphthaloylate, m.p. 135°. The identity of 9-methylcarbazole-9-phthaloylic and -3:6-diphthaloylic acids has been confirmed; the former is decarboxylated to 3-benzoyl-9-methylcarbazole, m.p. 84—85°. *Et* 9-ethylcarbazole-3:6-diphthaloylate, m.p. 178°, is obtained from the acid. Carbazole, succinic anhydride, and AlCl<sub>3</sub> in PhNO<sub>2</sub> form carbazole-3:6-bis-γ-ketobutyric acid, m.p. 285° (decomp.) [*Et* ester, m.p. 173°; 9-*Me* derivative, m.p. 268° (decomp.), and its *Et* ester, m.p. 142°], reduced (Clemmensen) to carbazole-3:6-dibutyric acid, m.p. 197—198°. 9-Acetylhexahydrocarbazole, AcCl, and AlCl<sub>3</sub> afford 6:9-diacetylhexahydrocarbazole, m.p. 123—125°, hydrolysed to the 6-acetyl compound, m.p. 73°, which is reduced to the 6-*Et* derivative, b.p. 182°/20 mm. (9-*p*-nitrobenzoyl derivative, m.p. 153°), also obtained by electrolytic reduction of 6-ethyltetrahydrocarbazole. F. R. S.

**Structure and properties of phenanthroline-ferric complexes.**—See this vol., 1324.

**Phenanthrene series. XI. Propanolamines of the type C<sub>14</sub>H<sub>9</sub>·CH(OH)·CH<sub>2</sub>·CH<sub>2</sub>·NR<sub>2</sub>.** J. VAN DE KAMP and E. MOSETTIG. **XII. Amino-alcohols derived from 1:2:3:4-tetrahydrophenanthrene.** A. BURGER and E. MOSETTIG (J. Amer. Chem. Soc., 1936, 58, 1568—1570, 1570—1572).—XI. 2-β-Dimethylamino-, m.p. 104.5—105° (hydrochloride, m.p. 193—193.5°; perchlorate, m.p. 167—167.5°), 2-β-diethylamino- (hydrochloride, m.p. 167—167.5°), 2-β-piperidino-, m.p. 88.5—89° (hydrochloride, m.p. 220—220.5°), 2-β-1':2':3':4'-tetrahydroisoquinolino-, m.p. 133.5—134° (hydrochloride, m.p. 208—209°), 3-β-dimethylamino- (hydrochloride, m.p. 177.5—178°; picrate, m.p. 175.5—176°), 3-β-diethylamino- (hydrochloride, m.p. 155.5—156°; picrate, m.p. 108—109°), 3-β-piperidino- (hydrochloride, m.p. 201—201.5°; picrate, m.p. 162.5—163.5°), 3-β-1':2':3':4'-tetrahydroisoquinolino-, m.p. 118.5—119° (hydrochloride, m.p. 219—220°), 9-β-dimethylamino- (hydrochloride, m.p. 171—171.5°; picrate, m.p. 175—175.5°), 9-β-diethylamino- (hydrochloride, m.p. 135—136°; salicylate, m.p. 113—113.5°), 9-β-piperidino- (hydrochloride, m.p. 184—185°; picrate, m.p. 138—139°), and 9-β-1':2':3':4'-tetrahydroisoquinolino- (hydrochloride, m.p. 228.5—229°), -propionylphenanthrenes are prepared from 2-, 3-, and 9-acetylphenanthrenes (1 mol.), paraformaldehyde (1.5 mols.), and the appropriate NHR<sub>2</sub>·HCl (1.5 mols.) in isoamyl alcohol. Reduction (H<sub>2</sub>, PtO<sub>2</sub>, 50—70% EtOH) of the above (usually as hydrochlorides) gives 2-γ-dimethylamino- (I), m.p. 97.5—98° (picrate, m.p. 156—157°), 2-γ-diethylamino- (II), m.p. 91—92°, 2-γ-piperidino-, m.p. 128—128.5° (hydrochloride, m.p. 184—185°), 2-γ-1':2':3':4'-tetrahydroisoquinolino-, m.p. 132.5—133° (hydrochloride, m.p. 212.5—213°), 3-γ-dimethylamino-, m.p. 99—100°, 3-γ-diethylamino- (hydrochloride, m.p. 141—143°), 3-γ-piperidino- (III) (hydrochloride, m.p. 185—185.5°), 3-γ-1':2':3':4'-tetrahydroisoquinolino-, m.p.

132.5—133° (hydrochloride, m.p. 212.5—213°), 9-γ-dimethylamino- (perchlorate, m.p. 142.5—143°; picrate, m.p. 167.5—168°), 9-γ-diethylamino-, 9-γ-piperidino-, m.p. 126—126.5° (picrate, m.p. 193.5—194°), and 9-γ-1':2':3':4'-tetrahydroisoquinolino-α-hydroxypropylphenanthrene, respectively. The O-Bz derivative hydrochlorides of (I) and (II) have m.p. 219—219.5° and 166—167°, respectively; the O-Ac derivative hydrochloride of (III) has m.p. 237.5—238°.

**XII. 1-Keto-1:2:3:4-tetrahydrophenanthrene (I)** (1 mol.), paraformaldehyde (2.5 mols.), and the appropriate NHR<sub>2</sub>·HCl (1.2 mols.) in isoamyl alcohol give 1-keto-2-dimethylaminomethyl-, m.p. 66—82° (hydrochloride, m.p. 199—200°), -2-diethylaminomethyl-, m.p. 60—61° (hydrochloride, m.p. 137—138°; picrate, m.p. 163—164°), -2-piperidinomethyl-, m.p. 97—98° (hydrochloride, m.p. 170—220°), and -2-1':2':3':4'-tetrahydroisoquinolinomethyl-, m.p. 121—123° (hydrochloride, m.p. 148—150°), -1:2:3:4-tetrahydrophenanthrenes, which are reduced (H<sub>2</sub>, PtO<sub>2</sub>, 90% EtOH) (as hydrochlorides) to 1-hydroxy-2-dimethylaminomethyl-, m.p. 146—147° (hydrochloride, m.p. 236°), -2-diethylaminomethyl- (II), not obtained cryst., -2-piperidinomethyl-, m.p. 133—134.5° (hydrochloride, m.p. 227—228°), and -2-1':2':3':4'-tetrahydroisoquinolinomethyl-, m.p. 159—160° (hydrochloride, m.p. 217°), -1:2:3:4-tetrahydrophenanthrene, respectively. (II) with Ac<sub>2</sub>O·C<sub>2</sub>H<sub>5</sub>N or EtOH·HCl at room temp. gives 2-diethylaminomethyl-3:4-dihydrophenanthrene (hydrochloride, m.p. 231—232°). 4-Keto-1:2:3:4-tetrahydrophenanthrene (III) affords [as for (I)] 4-keto-3-dimethylaminomethyl- (hydrochloride, m.p. 178—179°), -3-diethylaminomethyl- (hydrochloride, m.p. 153—154°; picrate, m.p. 149—151°), -3-piperidinomethyl-, m.p. 106—107° (perchlorate, m.p. 163—164°), and -3-1':2':3':4'-tetrahydroisoquinolinomethyl- (hydrochloride, m.p. 159—161°), -1:2:3:4-tetrahydrophenanthrenes, similarly reduced to 4-hydroxy-3-dimethylaminomethyl- (hydrochloride, m.p. 186—187°; O-Ac-derivative hydrochloride, m.p. 200°), -3-diethylaminomethyl- (hydrochloride, m.p. 172—173°; picrate, m.p. 177—179°), -3-piperidinomethyl- (hydrochloride, m.p. 178—179°), and -3-1':2':3':4'-tetrahydroisoquinolinomethyl- (IV), m.p. 149.5—151° (hydrochloride, m.p. 181—182°), -1:2:3:4-tetrahydrophenanthrene, respectively. (IV) is dehydrated [as for (II)] to 3-1':2':3':4'-tetrahydroisoquinolinomethyl-1:2-dihydrophenanthrene, m.p. 81—82° (hydrochloride, m.p. 227—228°).

Reduction (Al-Hg in moist Et<sub>2</sub>O or 2.5% Na-Hg in EtOH-AcOH) of the oxime of (I) gives 1-amino-1:2:3:4-tetrahydrophenanthrene, m.p. 61—63° [CHPh<sub>2</sub> derivative, m.p. 103—105°; hydrochloride, m.p. 256—257°; N-Me (hydrochloride, m.p. 258°; hydriodide, m.p. 243°) and NN-Me<sub>2</sub> (hydrochloride, m.p. 216°; picrate, m.p. 177—178°) derivatives]; the oxime of (III) is reduced (Al-Hg) to the 4-NH<sub>2</sub>-derivative (hydrochloride, m.p. 267—268°; NN-Me<sub>2</sub> derivative hydrochloride, m.p. 202°). H. B.

**Acetanilidoalkylbarbituric acids [5-alkyl-5-barbiturylacetanilides]. II. p-Carboethoxy-derivatives.** J. A. TILM and J. B. HOWARD (J. Amer. Chem. Soc., 1936, 58, 1805).—5-Alkylbarbituric acids

and  $p$ -CO<sub>2</sub>Et·C<sub>6</sub>H<sub>4</sub>·NH·CO·CH<sub>2</sub>Cl give (method: A., 1935, 1507) *Et* 5-ethyl-, 5-isopropyl-, 5-*n*- and -isobutyl-, 5-isoamyl-, and 5-allyl-5-barbituracetylacetanilide-4'-carboxylates, all m.p. >225° (decomp.). H. B.

**Tetra-alkylbarbituric acids.** A. W. DOX (J. Amer. Chem. Soc., 1936, 58, 1633—1635).—Methylation (CH<sub>2</sub>N<sub>2</sub>) or ethylation (diazoethane) of 5:5-di- and 1:5:5-tri-alkylbarbituric acids gives almost quant. yields of the 1:3:5:5-tetra-alkyl derivatives. The following are described: 1:3-dimethyl-5:5-diethyl- (I), m.p. 37° [also prepared from CEt<sub>2</sub>(COCl)<sub>2</sub> and CO(NHMe)<sub>2</sub> at 135—150°], 5-phenyl-1:3-dimethyl-5-ethyl-, m.p. 88—89°, 5-phenyl-1:3:5-triethyl-, m.p. 129°, 3-phenyl-1-methyl-5-ethyl-5-propyl-, m.p. 78°, 3-benzyl-1-methyl-5:5-diethyl-, m.p. 73°, and -1:5:5-triethyl- and 1:3-dimethyl-5-ethyl-5-hexyl-, b.p. 165—170°/12 mm., -5-isoamyl-, and -5- $\alpha$ -methylbutyl-barbituric acids. The *O*-methyl-5:5-diethylbarbituric acid of Marotta and Rosanova (A., 1932, 1041) is impure (I). H. B.

**N-Piperazinyl dyes. Azo-dyes.** I. V. PRELOG and D. KOHLBACH (Coll. Czech. Chem. Comm., 1936, 8, 377—389).—*N*-Phenylpiperazine (I) and PhN<sub>2</sub>Cl give 1-phenylpiperazine-4-azobenzene, m.p. 154—154.5°, decomposed by HCl into N<sub>2</sub>, PhOH, and (I). Similarly the substance previously (A., 1934, 196) regarded as *p*-piperazinylazobenzene-*p*'-sulphonic acid is 1-phenylpiperazine-4-azobenzene-*p*-sulphonic acid. However, (I) couples with some diazonium salts in the *p*-position of the Ph; *p*-1-piperazinoazobenzene-*p*'-sulphonamide (II) is thus obtained. 1-Acetyl-4-phenylpiperazine (III) (prep. by Ac<sub>2</sub>O or AcCl) with the appropriate diazonium salts gives *p*-1-4-acetyl-piperazinoazobenzene, m.p. 222°, and the *Ac* derivative of (II) and thence *p*-1-piperazinoazobenzene, m.p. 162—163°, and (II). (I) or (III) with HNO<sub>2</sub> gives 1-nitroso-4-*p*-nitrosophenylpiperazine, m.p. 155°, reduced by SnCl<sub>2</sub> to 1-*p*-aminophenylpiperazine (trihydrochloride, m.p. >300°; Bz<sub>2</sub> derivative, m.p. 226.5°), which by diazotisation and coupling yields 2:4-diamino-4'-*N*-piperazinoazobenzene (tetrahydrochloride, an effective bactericide for some, not all, organisms), 2:6-diaminopyridine-3- (IV), 1-phenyl-3-methylpyrazol-5-one-4-, and 2-naphthol-1-azo-*p*-N-piperazinobenzene (dihydrochloride). (IV) gives a red tetrahydrochloride, decomposed by H<sub>2</sub>O into a black trihydrochloride (V); the colour of (IV) is a max. in 0.6—1*N*-HCl; this fact, the absorption spectra of the salts and of 2:6-diaminopyridine-3-azo-*p*-dimethylaminobenzene (shows no colour changes in acid; trihydrochloride) lead to the following structure for (V):

R. S. C.

**Synthesis of 6-hydroxy-4-methylpyrimidine-5-acetic acid and 4-methyl-5-aminomethyluracil.** W. T. CALDWELL and W. M. ZIEGLER (J. Amer. Chem. Soc., 1936, 58, 1749—1751).—4-Methyluracil-5-acetic acid (I), POCl<sub>3</sub>, and PCl<sub>5</sub> lead to 2:6-dichloro-4-methylpyrimidine-5-acetic acid, m.p. 156—157°, reduced (method: Gabriel and Colman, A., 1899, i, 638) to 6-hydroxy-4-methylpyrimidine-5-acetic acid,

m.p. 147—149°. The hydrazide, m.p. >375°, of (I) is converted into the azide (II) and thence by 50% AcOH into 4-methyl-5-aminomethyluracil (III), m.p. >335° (darkening) [acetate, m.p. >360° (darkening)]. The *N*-CO<sub>2</sub>Et-derivative, m.p. 214—215°, of (III) is obtained from (II) and EtOH; it could not be hydrolysed (conc. HCl at 130—140°) to (III).

H. B.

**Pyrimidines. CLII. Hydrogenation and hydrogenolysis of [ethyl] 2-keto-[4-phenyl-6-methyl]-1:2:3:4-tetrahydropyrimidine]-5-carboxylate] to  $\beta$ -benzyl- and  $\beta$ -hexahydrobenzyl-*n*-butyl alcohol.** K. FOLKERS (J. Amer. Chem. Soc., 1936, 58, 1558—1560; cf. A., 1934, 783).—Hydrogenolysis occurs when the ester is treated with H<sub>2</sub> in presence of Cu-Ba-Cr oxides (A) and EtOH at 250° and gives 28.6% of a mixture, b.p. 77—79°/2.5 mm., of  $\beta$ -benzyl- (I), b.p. 81—81.5°/2 mm., and  $\beta$ -hexahydrobenzyl- (II), b.p. 83—84°/2 mm., -*n*-butyl alcohols. CHPh·Cac·CO<sub>2</sub>Et is reduced [H<sub>2</sub>, (A), EtOH, 160°] to *Et*  $\beta$ -hydroxy- $\alpha$ -benzylbutyrate, b.p. 124—126°/3 mm., dehydrated (P<sub>2</sub>O<sub>5</sub> in C<sub>6</sub>H<sub>6</sub>) to *Et*  $\alpha$ -benzylcrotonate, b.p. 125—127°/3 mm.; short treatment of this with H<sub>2</sub> and (A) in EtOH at 250° and subsequent hydrolysis (EtOH-NaOH), gives (I) and  $\alpha$ -benzylbutyric acid, b.p. 123—124°/2 mm., whilst more prolonged treatment affords a mixture which is further reduced (Raney Ni, 180°) to (II).

H. B.

**Magneto-chemical investigations of organic substances. IX. Magnetic behaviour of nitro-gen-radicals.** E. MÜLLER and W. WIESEMANN (Ber., 1936, 69, [B], 2157—2163; cf. A., 1935, 1453).—Wieland's bisdi-*p*-anisylidiphenylenchydrazine could not be freed from a solid paramagnetic impurity. The magnetic behaviour of 4:4'-dibenzyl-dipyridinium is not in harmony with the presence of two independent electron spins and supports the quinonoid formulation of the compound. Generally, wherever valency tautomerism with formation of the quinonoid condition is possible the magnetic behaviour is in accord only with such quinonoid structure, whereas the chemical behaviour of the substances points to the existence of free radicals. Attempts to obtain the 4:4'-dibenzyl-dipyridinium subiodide of Weitz gave a compound, m.p. 187—193°, of 1 mol. of radical + 1 mol. of subiodide which in the solid condition cannot be regarded as a radical, but further conclusions as to its structure cannot be reached until measurements have been made with its solutions. The magnetic behaviour of tetratolylhydrazinium perchlorate supports Weitz' formulation, and since the paramagnetism depends preponderantly on one spin moment, the alternative NAr<sub>2</sub>·NAr<sub>2</sub>X is preferred.

H. W.

**Experiments in the heterocyclic series.** E. C. WAGNER and J. K. SIMONS (J. Chem. Educ., 1936, 13, 394).—A correction (cf. this vol., 1000).

L. S. T.

**Methyl and phenyl derivatives of nitrophthalhydrazides [nitrophthalaz-1:4-diones].** C. N. ZELLNER and G. DOUGHERTY (J. Amer. Chem. Soc., 1936, 58, 1811—1813).—3-Nitrophthalic anhydride (I) and NHMe·NH<sub>2</sub>·AcOH in aq. AcOH (distilled off

during reaction) give two 5-nitro-N-methylphthalaz-1:4-diones, m.p. 305° (II) (*Ac* derivative, m.p. 211°) and 273° (III) (*Ac* derivative, m.p. 144°). Similarly, (I) and  $(\text{NHMe})_2$  afford 5-nitro-2:3-dimethylphthalaz-1:4-dione, m.p. 203°, whilst (I) and  $\text{NMe}_2\text{NH}_2$  yield 3-nitro-N-dimethylaminophthalimide, m.p. 200—201°. Methylation ( $\text{Me}_2\text{SO}_4$ , dil. alkali) of 5-nitrophthalaz-1:4-dione ["3-nitrophthalhydrazide"] (IV) gives two ON-Me derivatives, m.p. 207° and 138—139°, also obtained by similar methylation of (II) and (III), respectively. These results indicate that (IV) is not 3-nitro-N-aminophthalimide (cf. Mihailescu and Protopopescu, A., 1930, 1434) but has the constitution assigned. 6-Nitro-N-methyl-, m.p. 310—311° and 271—272° (*Ac* derivatives, m.p. 213—214° and 170—171°, respectively), and -2:3-dimethyl-, m.p. 203·5°, -phthalaz-1:4-diones are similarly prepared from 4-nitrophthalic anhydride (V).  $\text{NHPh}\cdot\text{NH}_2$  and (V) in *AcOH* give 4-nitro-N-anilinophthalimide, m.p. 182°, and a 6-nitro-N-phenylphthalaz-1:4-dione, m.p. 253° (*Ac* derivative, m.p. 186°); (I) similarly affords 3-nitro-N-anilinophthalimide, m.p. 198—199°. All m.p. are corr. H. B.

**3-Aminophthalhydrazide.** K. GLEU and K. PFANNSTIEL (J. pr. Chem., 1936, [ii], 146, 137—150).—Me benzisooxazolone-3-carboxylate (I), when heated for a short time with conc. aq.  $\text{N}_2\text{H}_4$ , gives 3-aminophthaloylhydrazine (II),  $\text{NH}_2\cdot\text{C}_6\text{H}_3(\text{CO})\cdot\text{N}\cdot\text{NH}_2$ , yellow, m.p. 250—251° or about 257° (slow heating), probably by way of the 3-hydrazide and 3-hydroxylaminophthaloylhydrazine. (II) is also obtained from 3-aminophthalimide (III) and aq.  $\text{N}_2\text{H}_4$  at 75°.

5-Aminophthalaz-1:4-dione (IV),  $\text{NH}_2\cdot\text{C}_6\text{H}_3<\begin{smallmatrix} \text{CO}\cdot\text{NH} \\ \text{CO}\cdot\text{NH} \end{smallmatrix}$ , m.p. 328° (hydrochloride,  $+0\cdot5\text{H}_2\text{O}$ , m.p. 328°, at 100° loses the  $\text{H}_2\text{O}$  rapidly and *HCl* slowly, stable to light), is obtained by heating (I) and  $\text{N}_2\text{H}_4$  for a longer time, from (III) and  $\text{N}_2\text{H}_4$  at  $>75^\circ$ , or by heating (II) above the m.p. or with conc. *HCl*. The *N*-Me derivative of (I) gives 1-methylbenzisooxazolone-4-carbonhydrazone, m.p. 173° (decomp.) (hydrochloride,  $+ \text{H}_2\text{O}$ , decomp. 200°), and thence 5-methylaminophthalazdione (V), m.p. about 310—325° (decomp.). (IV) and  $\text{Me}_2\text{SO}_4\text{--NaOH}$  give the  $\text{Me}_2$  derivative (VI), m.p. 230°. (I) and  $\text{NHPh}\cdot\text{NH}_2$  give 3-aminophthal- (or -phthaloyl-)phenylhydrazide (VII), m.p. 222° (*Ac* derivative, m.p. 178°; cf. Bogert *et al.*, A., 1909, i, 305). (II) and (IV), but not (V), (VI), or (VII), are sol. in alkali. (IV) fluoresces in acid, (V) in alkaline solution. (II) and (VI) do not fluoresce. The chemiluminescence of (IV) is best observed with  $\text{H}_2\text{O}_2$  and a trace of hæmin. The other compounds show no chemiluminescence. R. S. C.

**Quinazolines.** XLIII. Synthesis of a quinazoline derivative structurally analogous to cusparine. D. PAPA and M. T. BOGERT (J. Amer. Chem. Soc., 1936, 58, 1701—1703).—2-3':4'-Methylenedioxyethyl-4-quinazoline, new m.p. 316—317° (decomp.) (all m.p. are corr.), is reduced (method: A., 1935, 760) to 2-β-3':4'-methylenedioxyphenylethyl-4-quinazoline, m.p. 239—240°, methylated ( $\text{Me}_2\text{SO}_4$ , aq. *NaOH*) to the 3-Me derivative, m.p. 94—94·5°, and converted by  $\text{POCl}_3 + \text{PCl}_5$  into 4-

chloro- and thence ( $\text{MeOH--NaOMe}$ ) into 4-methoxy-2-β-3':4'-methylenedioxyphenylethylquinazoline, m.p. 67—68°. The following are similarly prepared: 2-p-methoxystyryl-, m.p. 284—285°, 2-β-p-anisylethyl-, m.p. 213—214°, and 2-β-p-anisylethyl-3-methyl-, m.p. 118—118·5°, -4-quinazoline; 4-chloro-, m.p. 125—128°, and 4-methoxy-, m.p. 84·5—85·5°, -2-β-p-anisylethylquinazoline. 2-Methyl-4-quinazoline is methylated ( $\text{Me}_2\text{SO}_4$ ) to the 2:3-Me derivative, m.p. 111—111·5°. It is now stated that the "gallopine" of *loc. cit.* should be galipoline. H. B.

**Semiquinones of neutral-red and safranines.** L. MICHAELIS (J. Amer. Chem. Soc., 1936, 58, 1816—1817).—Dilution ( $\text{H}_2\text{O}$ ) of solutions of neutral-red, phenosafranine, or commercial "safranine" in conc. *HCl* until bluish-violet and subsequent treatment with  $\text{CrCl}_2$  or *Zn* dust gives intense green (semiquinone state) and then almost colourless solutions; re-oxidation ( $\text{K}_2\text{S}_2\text{O}_8$ ) reverses the two-fold colour change. H. B.

**Synthesis of pyridylisoquinoline derivatives.** S. SUGASAWA and M. KURIYAGAWA (Ber., 1936, 69, [B], 2068—2071).—Homoveratrylamine and Et nicotinate at 150—170° give nicotinoyl-β-3:4-dimethoxyphenylethylamide [hydrochloride ( $+1\text{H}_2\text{O}$ )] transformed by  $\text{POCl}_3$  in boiling *PhMe* into 6:7-dimethoxy-1-3'-pyridyl-3:4-dihydroisoquinoline (I), m.p. 123—124° [dimethiodide, m.p. 229° (decomp.)]. The dimethochloride of (I) is hydrogenated (Adams) to the methochloride, decomp. 275°, of 6:7-dimethoxy-1-3'-pyridyl-2-methyl-1:2:3:4-tetrahydroisoquinoline. *N*-Methylhexahydronicotinoyl-β-3:4-dimethoxyphenylethylamide, m.p. 98°, is converted by  $\text{POCl}_3$  in boiling *PhMe* into a non-cryst. base which yields a dihydriodide, decomp. 208—209°, and a dipicrolonate, decomp. 245° after softening at 230°. H. W.

**Light absorption and tautomerism of uric acid.**—See this vol., 1317.

**Murexide and leucomurexide.** D. DAVIDSON (J. Amer. Chem. Soc., 1936, 58, 1821—1822).—Murexide (I) is obtained in good yield (cf. Kuhn and Lyman, this vol., 1000) from alloxantin and  $\text{NH}_4\text{OAc}$  in boiling glacial *AcOH*. (I) is reduced ( $\text{Na}_2\text{S}_2\text{O}_4$ , aq.  $\text{NH}_3$ ) to leucomurexide [ $\text{NH}_4$  dihydropurpurate], which is readily oxidised [air;  $\text{K}_3\text{Fe}(\text{CN})_6$ ] to (I). H. B.

**Semiquinone of the flavin dyes, including vitamin-B<sub>2</sub>.** L. MICHAELIS, M. P. SCHUBERT, and C. V. SMYTHE (Science, 1936, 84, 138—139).—A colour reaction, affording evidence for the existence of a semiquinone in neutral solutions of the flavins, is described. L. S. T.

**Formation of a synthetic ferment from 6:7-dimethyl-9-l-araboflavin-5'-phosphoric acid.** R. KUHN, H. RUDY, and F. WEYGAND (Ber., 1936, 69, [B], 2034—2036; cf. this vol., 1418).—6:7-Dimethyl-9-l-araboflavin-5'-phosphoric acid (I) gives with the colloidal carrier obtained from the yellow enzyme a non-fluorescent, non-dialysable yellow chromoprotein of high catalytic activity which is resolved into its components by acid. 6:7-Dimethyl-9-l-araboflavin is transformed by  $\text{CPh}_3\text{Cl}$  in anhyd.  $\text{C}_5\text{H}_5\text{N}$  into 5'-triphenylmethyl-6:7-dimethyl-9-l-araboflavin, m.p.

262—263° (decomp.). The corresponding 2' : 3' : 4'-triacetate, m.p. 240° (decomp.), is transformed by boiling 80% AcOH into 6 : 7-dimethyl-9-l-araboflavin 2' : 3' : 4'-triacetate, m.p. 209° (corr.), which when treated with POCl<sub>3</sub> in C<sub>5</sub>H<sub>5</sub>N gives (I) (*Ag*, *Na*, and *Ca* salts). H. W.

**Porphyrins. XXXVIII. Synthesis of porphyrins and their derivatives.** H. FISCHER, R. J. DOYLE, and W. GLEIM (*Annalen*, 1936, 525, 24—43).—Pyrrole-2-aldehyde (I) and cryptopyrrole-carboxylic acid in AcOH containing 48% HBr give 3' : 5'-dimethylpyrromethene-4'-propionic acid hydrobromide (II), darkens above 190° [*Me* ester hydrobromide, m.p. 151° (corr.)]. With Br in AcOH at room temp. (II) gives a mixture of Br<sub>2</sub>- and Br<sub>3</sub>-derivatives whereas at 100° 3 : 4 : 5-tribromo-3'-methyl-5'-bromo-methylpyrromethene-4'-propionic acid hydrobromide (III) results; (III) is converted by boiling MeOH or H<sub>2</sub>O into 1' : 8' : 1 : 2 : 7 : 8-hexabromo-3 : 6-dimethyl- $\alpha$ , $\beta$ -

$\gamma$ , $\beta$ -dehydrobilan-4 : 5-dipropionic acid (IV), m.p. 146°. Analogously (I) and hæmopyrrolecarboxylic acid yield 4' : 5'-dimethylpyrromethene-3'-propionic acid hydrobromide (*Me* ester hydrobromide), whence the hydrobromides of the Br<sub>2</sub>-derivative, decomp. about 210°, and Br<sub>3</sub>-compound (V). Treatment of (III) or (V) with (—CH<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub> and AcCO<sub>2</sub>H at 180—190° gives 1 : 5-dimethylporphin-2 : 6-dipropionic acid [*Me*<sub>2</sub> ester, m.p. 302° (corr.), and its *Cu* salt]. Et 5-aldehyde-2-methylpyrrole-3-carboxylate and Et pyrrole-2-carboxylate in AcOH containing 48% HBr yield Et<sub>2</sub> 5'-methylpyrromethene-5 : 4'-dicarboxylate hydrobromide, m.p. 193° (decomp.), which could not be further converted into the corresponding porphyrin or porphin. (I) and 3 Br<sub>2</sub> in Et<sub>2</sub>O give 3 : 4 : 5 : 3' : 4' : 5'-hexabromopyrromethene (VI), decomp. >160° (hydrobromide, decomp. about 160°), which with CH<sub>2</sub>O and C<sub>5</sub>H<sub>5</sub>N gives unchanged material and a compound, C<sub>19</sub>H<sub>6</sub>N<sub>4</sub>Br<sub>10</sub>. Addition of CH<sub>2</sub>Cl·OEt to Et 2-methylpyrrole-3-carboxylate in EtOH, Et<sub>2</sub>O, or C<sub>6</sub>H<sub>6</sub> gives Et<sub>2</sub> 2 : 6-dimethyl-4 : 8-dihydrobenzodipyrrole-3 : 5-dicarboxylate (VII), m.p. 331° (block) after subliming at 280°, also obtained by means of HCl-CH<sub>2</sub>O, the constitution of which is established by its reduction (HI-AcOH) to 2 : 3 : 5-trimethylpyrrole;

it is possibly identical with the Et<sub>2</sub> 2 : 6-dimethylbenzodipyrrole-3 : 5-dicarboxylate of Ruggli *et al.* (this vol., 614). (VI) and 5 : 5'-dimethylpyrromethene-4 : 4'-dipropionic acid hydrobromide in AcCO<sub>2</sub>H at 190° give *Me*<sub>2</sub> porphin-1 : 4-dipropionate, m.p. 215—216° (*Cu* salt); at 160° *Me*<sub>2</sub> 5 : 6 : 7 : 8-tetrabromoporphin-1 : 4-dipropionate, m.p. 180°, is produced. 3 : 3' : 5 : 5'-Tetramethyl-4 : 4'-diethylpyrromethene hydrobromide, (VI), and AcCO<sub>2</sub>H at 190° afford 2 : 3-dimethyl-1 : 4-diethylporphin (*Cu* salt), whilst at 160° 5 : 6 : 7 : 8-tetrabromo-2 : 3-dimethyl-

1 : 4-diethylporphin is produced. Porphin-1 : 3 : 5 : 7-tetrapropionic acid, m.p. 265—266°, is derived from 4 : 5 : 3' : 4'-tribromo-5'-methylpyrromethene-3 : 4'-dipropionic acid hydrobromide and AcCO<sub>2</sub>H at 190°.

H. W.

**Chlorophyll. LXXIV. Quantitative dehydrogenation of phæophorbide-a.** H. FISCHER and W. LAUTSCH (*Annalen*, 1936, 525, 259—270; cf. this vol., 1273).—The relationship of the phæophorbide to the porphin series is proved by quant. reaction of phæophorbide-a with Ag<sub>2</sub>O (2 mols.) or AgOAc (4 mols.) in hot AcOH (3 min.) to a product, which with CH<sub>3</sub>N<sub>2</sub> gives 10-acetoxyvinylphæoporphyrin-a<sub>5</sub> *Me*<sub>2</sub> ester, m.p. >360° (additive product with CHN<sub>2</sub>·CO<sub>2</sub>Me, m.p. 302°; converted into a hæmin, m.p. >360°; *oxime*, m.p. >360°). This with H<sub>2</sub>-Pd in EtOAc absorbs 3 H<sub>2</sub> to give 10-acetoxyphæoporphyrin-a<sub>5</sub> *Me*, ester, m.p. 305°, with HBr-AcOH, followed by MeOH, affords 10-acetoxy-2- $\alpha$ -methoxyphæoporphyrin-a<sub>5</sub> *Me*<sub>2</sub> ester, m.p. >360°, and a little 2- $\alpha$ -methoxyrhodoporphyrin, and with MeOH-C<sub>6</sub>H<sub>5</sub>N, followed by CH<sub>2</sub>N<sub>2</sub>, gives vinylrhodoporphyrin *Me*<sub>2</sub> ester, m.p. 172°. Structures are confirmed spectrographically. R. S. C.

**Chlorophyll and hæmin derivatives in organic minerals.**—See this vol., 1358.

**Optical absorption of the porphyrins. VII.**—See this vol., 1318.

**Benzisooxazolone-4-carboxylic acids and indazolone-4-carboxylic acids.** K. GLEV and K. FRANNSTIEL (*J. pr. Chem.*, 1936, [ii], 146, 129—136).—Electrolytic reduction of 3-nitrophthalic acid gives quantitatively benzisooxazolone-3-carboxylic acid (I), m.p. 191° [*Ag* salt; *Ac*, m.p. 215° (decomp. from 196°), *N-Et*, m.p. 138°, and *N-Me* derivative, m.p. 163° (*Me* ester, m.p. 66°); *Me* ester (prep. by H<sub>2</sub>SO<sub>4</sub>-MeOH or from the *Ag* salt), +H<sub>2</sub>O, m.p. about 110° (decomp.) or (anhyd.) about 119° (*Ac* derivative, m.p. 119°)]. The *N*-substituted but not the NH derivatives can be sharply titrated using phenolphthalein. The acid gives by diazo-reactions 3-chloro-, -iodo-, and -hydroxy-phthalic acid; if the diazonium solution is treated with KI-SO<sub>2</sub> it gives indazolone-4-carboxylic acid, m.p. 312° (decomp.). R. S. C.

(I)

**Acenaphthene series. II.** A. C. SIRCAR and S. C. SEN (*J. Indian Chem. Soc.*, 1936, 13, 482—483; cf. A., 1932, 286).—Acenaphthenequinone, *p*-NHAc-C<sub>6</sub>H<sub>4</sub>·CHO, and cold NH<sub>3</sub>-C<sub>5</sub>H<sub>11</sub>·OH give the oxazole, but more drastic treatment with the same reagents affords the glyoxaline, m.p. 250° (decomp.). Other aldehydes do not react similarly. R. S. C.

**Doebner reaction. XII.** R. CIUSA and F. BELLINO (*Gazzetta*, 1936, 66, 452—455).—2-2'-Furylcinchonic acid, new m.p. 227° (cf. A., 1922, i, 1062), prepared as before, and also by the Doebner reaction, forms *K*, *Na* (+H<sub>2</sub>O), and *Cu* (+0.5H<sub>2</sub>O) salts, and a *Me* ester, m.p. 100°. In pharmacological use, it eliminates uric acid from the system in a similar manner to atophan, and is less toxic than the latter. E. W. W.

**Vitamin-B<sub>1</sub>. XIV. Sulphite cleavage. IV.** The thiazole half. E. R. BUCHMAN (J. Amer. Chem. Soc., 1936, 58, 1803—1805; cf. Clarke and Gurin, A., 1935, 1510).— $\alpha$ -Acetyl- $\gamma$ -butyrolactone and  $\text{SO}_2\text{Cl}_2$  give the  $\alpha$ -Cl-derivative, b.p. 84—86°/3 mm., converted by dil. HCl at 100° into  $\gamma$ -chloro- $\gamma$ -acetylpropyl alcohol, b.p. 85—110°/3 mm., which with  $\text{HCS}\cdot\text{NH}_2$  in EtOH at room temp. affords 4-methyl-5- $\beta$ -hydroxyethylthiazole (I), b.p. 93—95°/2 mm., also prepared (in lower yield) from  $\text{HCS}\cdot\text{NH}_2$  and the unstable Br-compound from  $\text{CH}_3\text{Ac}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH}$  and Br in  $\text{H}_2\text{O}$ . (I) and conc. HCl at 145° give 4-methyl-5- $\beta$ -chloroethylthiazole, b.p. 74—75°/3 mm. H. B.

**Synthesis of thiochrome.** F. BERGEL and A. R. TODD (Nature, 1936, 138, 406).—Condensation of 4-chloro-2-methyl-5-chloromethylpyrimidine, synthesised from 4-hydroxy-2-methylpyrimidine-5-acetic ester, with 2-amino-4-methyl-5- $\beta$ -hydroxyethylthiazole gives a product identical with thiochrome prepared from aneurin (A., 1935, 1286). The blue fluorescence shown by thiochrome appears to be a property of the condensed ring system present, since other compounds of this type, which all have a similar fluorescence, have been prepared. This synthesis confirms the structure of aneurin (this vol., 1276).

L. S. T.

**l-Peganine from the blossoms and stems of Peganum Harmala.** L. A. D. ROSENFELD and D. G. KOLESNIKOV (Ber., 1936, 69, [B], 2022—2023).—l-Peganine,  $\text{C}_{11}\text{H}_{12}\text{ON}_2$ , m.p. 212°,  $[\alpha]_D^{24}$  —211.0° in  $\text{CHCl}_3$  (hydrochloride, m.p. 206—207°; picrate, m.p. 211°; aurichloride, m.p. 132°), isolated from *P. Harmala*, L., appears identical with the alkaloid obtained by Spath (this vol., 489) from *Adhatoda vasica*, Nees. H. W.

**Peganine. XII. Peganine derivatives and their picrolonates.** E. SPATH, F. KUFFNER, and J. LINTNER (Ber., 1936, 69, [B], 2052—2058; cf. this vol., 489).—Mainly a correction of the work of Narang *et al.* (A., 1935, 765, 995, 1387; this vol., 869). Contrary to these authors, o-aminobenzylsuccinamic acid is transformed by anhyd. NaOAc in  $\text{H}_2$  at 140—150° not into the base

$\text{CH}_2\left\langle \begin{array}{c} \text{N}=\text{C}\cdot\text{CH}_2 \\ \text{C}_6\text{H}_4\cdot\text{N}\cdot\text{CO} \end{array} \right\rangle \text{CH}_2$  (I) but into  $\Delta^9$ -pegen-1-one (II) identical with that derived from o-aminobenzylsuccinimide and further identified by reduction with  $\text{Na}\cdot\text{C}_5\text{H}_{11}\cdot\text{OH}$  to peganine (III). In an attempt to obtain (I) synthetically o- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{OMe}$  is converted by  $(\cdot\text{CH}_2\cdot\text{CO})_2\text{O}$  followed by distillation in a high vac. into the compound,

$(\cdot\text{CH}_2\cdot\text{CO})\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{OMe}$ , m.p. 93—95°, transformed by HBr in  $\text{C}_6\text{H}_6$  into the corresponding bromide, m.p. 132—134°, which passes into (II) when treated with liquid  $\text{NH}_3$  and then distilled in a high vac. The base  $\text{C}_{11}\text{H}_{14}\text{N}_2$  obtained by the reduction of (II) or peganine (IV) is identified as 1-o-aminobenzylpyrrolidine, not (III); this view is confirmed by the observations that it gives a dipicrolonate whereas (III) affords only a monopicrolonate, m.p. 191—193° (vac.). The electrolytic reduction is complete within 1 hr. The monopicrolonates of (IV), m.p. 177—179° (vac.; decomp.), pegan-3-ol, m.p.

188—190° (vac.; decomp.), and  $\Delta^9$ -pegene, m.p. 236—237° (vac.; decomp.), are incidentally described.

H. W.

**Ethers and hetero-ethers of morphine and its isomerides.** B. F. FARIS and L. SMALL (J. Org. Chem., 1936, 1, 194—208).—The prep. of the following derivatives is described; m.p. marked \* were determined in an evacuated tube: ethyldihydromorphine, b.p. 170°/high vac.,  $[\alpha]_D^{24}$  —135.9° in EtOH [H tartrate, m.p. 167°,  $[\alpha]_D^{25}$  —59.4° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 260°\*]; benzyldihydromorphine, m.p. 95—97°,  $[\alpha]_D^{25}$  —88.1° in EtOH [hydrochloride (+ $\text{H}_2\text{O}$ ), m.p. 233—235°\*,  $[\alpha]_D^{25}$  —52.1° in  $\text{H}_2\text{O}$ ; hydrobromide (+ $\text{H}_2\text{O}$ ), m.p. 193—195°\*,  $[\alpha]_D^{24}$  —44° in  $\text{H}_2\text{O}$ ; hydriodide, m.p. 215—217°\*,  $[\alpha]_D^{24}$  —45.3° in  $\text{H}_2\text{O}$ ; perchlorate, m.p. 188—192°,  $[\alpha]_D^{25}$  —59.5° in EtOH; methiodide, m.p. 242—244°\*,  $[\alpha]_D^{25}$  —43.2°]; methoxy-methyldihydromorphine, m.p. 99—101°,  $[\alpha]_D^{24}$  —15.4.5° in EtOH (hydrochloride, m.p. 124—126°,  $[\alpha]_D^{24}$  —78° in  $\text{H}_2\text{O}$ ; sulphate, m.p. 49°,  $[\alpha]_D^{24}$  —72.8° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 201—203°\*,  $[\alpha]_D^{24}$  —61.8° in  $\text{H}_2\text{O}$ ); heterodihydrocodeine, m.p. 216.5—217°\*,  $[\alpha]_D^{25}$  —178.0° in EtOH [hydrochloride, m.p. 299—299.5°\*,  $[\alpha]_D^{25}$  —136.5° in  $\text{H}_2\text{O}$ ; hydriodide, m.p. 269°\*,  $[\alpha]_D^{25}$  —98.9° in  $\text{H}_2\text{O}$ ; perchlorate, m.p. 258—260°\* (decomp.),  $[\alpha]_D^{25}$  —110° in  $\text{H}_2\text{O}$ ; hydrogen fumarate, m.p. 215—216°,  $[\alpha]_D^{25}$  —110° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 260—261°\*,  $[\alpha]_D^{25}$  —91.4° in MeOH]; heteroethylmorphine (+ $\text{H}_2\text{O}$ ), m.p. 110—112°,  $[\alpha]_D^{23}$  —178.8° in EtOH [hydrochloride (+3 $\text{H}_2\text{O}$ ), m.p. 241—243°\*,  $[\alpha]_D^{24}$  —134.9° in  $\text{H}_2\text{O}$ ; hydrobromide (+2 $\text{H}_2\text{O}$ ), m.p. 285—287°\*,  $[\alpha]_D^{25}$  —119.2° in  $\text{H}_2\text{O}$ ; hydriodide (+2 $\text{H}_2\text{O}$ ), m.p. 171—174°, solidifies and remelts at 282°\* (decomp.),  $[\alpha]_D^{25}$  —115.8° in  $\text{H}_2\text{O}$ ; perchlorate, m.p. 249—250°\* (decomp.); methiodide, m.p. 255—265°\* (decomp.)]; heteroethyldihydromorphine, m.p. 189—190°,  $[\alpha]_D^{23}$  —164.8° in EtOH [hydrochloride (+3 $\text{H}_2\text{O}$ ), m.p. 165—170°\*, solidifies and remelts at 274—276°\*,  $[\alpha]_D^{24}$  —121.7° in  $\text{H}_2\text{O}$ ; hydrobromide (+2 $\text{H}_2\text{O}$ ), m.p. 282—284°\*,  $[\alpha]_D^{25}$  —125.1° in  $\text{H}_2\text{O}$ ; hydriodide, m.p. 291—293°\*,  $[\alpha]_D^{25}$  —110.6° in  $\text{H}_2\text{O}$ ; perchlorate, m.p. 234—235°\*,  $[\alpha]_D^{23}$  —98° in EtOH; methiodide, m.p. 250—251°\*,  $[\alpha]_D^{23}$  —79.4° in MeOH]; ethyl- $\alpha$ -isomorphine, m.p. 128—130°,  $[\alpha]_D^{23}$  —143.7° in EtOH [methiodide, m.p. 243°\*,  $[\alpha]_D^{21}$  —91.6°]; ethyldihydro- $\alpha$ -isomorphine (+ $\text{H}_2\text{O}$ ), m.p. 86—91°,  $[\alpha]_D^{24}$  —110° in MeOH [anhyd. base, m.p. 104°, b.p. 130°/high vac.; hydrogen tartrate (+ $\text{H}_2\text{O}$ ), m.p. 109—112°,  $[\alpha]_D^{23}$  —66° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 277°\*,  $[\alpha]_D^{23}$  —76.2° in  $\text{H}_2\text{O}$ ]; heteroisocodeine, m.p. 206.5—207°\*, sublimes at 155°/high vac.,  $[\alpha]_D^{22}$  —185.5° in MeOH (methiodide, m.p. 227—228°\*,  $[\alpha]_D^{23}$  —105.4° in  $\text{H}_2\text{O}$ ); heterodihydroisocodeine, m.p. 198—200°,  $[\alpha]_D^{25}$  —118.1° in EtOH (hydrochloride, m.p. 273—275°\*,  $[\alpha]_D^{24}$  —111.1° in  $\text{H}_2\text{O}$ ; hydriodide, m.p. 287—288°\*,  $[\alpha]_D^{24}$  —85.2° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 245—248°\*,  $[\alpha]_D^{24}$  —77.9 in  $\text{H}_2\text{O}$ ); heteroethyl- $\alpha$ -isomorphine, m.p. 161—162°\*, b.p. 170°/high vac.,  $[\alpha]_D^{22}$  —205.1° in MeOH [hydrochloride, m.p. 247—248°\* (decomp.),  $[\alpha]_D^{25}$  —164.2° in  $\text{H}_2\text{O}$ ; hydriodide, m.p. 264°\* (decomp.),  $[\alpha]_D^{25}$  —132.7° in  $\text{H}_2\text{O}$ ; hydrobromide, m.p. 255—258°\* (decomp.),  $[\alpha]_D^{24}$  —150.2° in  $\text{H}_2\text{O}$ ; methiodide, m.p. 229—231°\*,  $[\alpha]_D^{24}$  —131.3° in  $\text{H}_2\text{O}$ ]; heteroethyldihydro- $\alpha$ -isomorphine, m.p. 210—212°,  $[\alpha]_D^{25}$  —128° in EtOH [hydrochloride, m.p. 300°\*,  $[\alpha]_D^{25}$  —125.7° in

H<sub>2</sub>O; *hydriodide*, m.p. 287°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -99.5° in H<sub>2</sub>O; *methiodide*, m.p. 256—258°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -86.1° in H<sub>2</sub>O; *ethyl- $\beta$ -isomorphine*, b.p. 170°/high vac. [*H sulphate*, m.p. 195—198°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -136.3° in H<sub>2</sub>O; *perchlorate*, m.p. 264—266°\* (decomp.), [ $\alpha$ ]<sub>D</sub><sup>25</sup> -113.2° in 40% EtOH; *fumarate*, m.p. 172—175°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -100.3° in EtOH]; *ethylidihydro- $\beta$ -isomorphine*, b.p. 210°/high vac. (*perchlorate*, m.p. 231—234°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -64.3° in H<sub>2</sub>O; *picrate*, m.p. 187—189°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -64.8° in EtOH); *heteroethyl- $\beta$ -isomorphine*, m.p. 209—211°\*, [ $\alpha$ ]<sub>D</sub> -60.1° in EtOH; *ethyl- $\gamma$ -isomorphine*, m.p. 183—184°, [ $\alpha$ ]<sub>D</sub><sup>22</sup> -75° in MeOH [*hydrochloride*, m.p. 298—300°\* (decomp.), [ $\alpha$ ]<sub>D</sub><sup>24</sup> -62.7° in H<sub>2</sub>O; *methiodide*, m.p. 252—253°\*, [ $\alpha$ ]<sub>D</sub><sup>21</sup> -40.8° in H<sub>2</sub>O]; *ethylidihydro- $\gamma$ -isomorphine*, m.p. 158—159°, [ $\alpha$ ]<sub>D</sub><sup>21</sup> -36.2° in MeOH (*fumarate*, m.p. 180—192°\*, [ $\alpha$ ]<sub>D</sub> -23.7° in H<sub>2</sub>O; *methiodide*, m.p. 252—253°\*, [ $\alpha$ ]<sub>D</sub><sup>21</sup> -40.8° in H<sub>2</sub>O); *hetero- $\psi$ -codeine*, m.p. 239—241°\*, [ $\alpha$ ]<sub>D</sub> -79.5° in MeOH [*hydrochloride*, m.p. 274—276°\* (decomp.), [ $\alpha$ ]<sub>D</sub><sup>22</sup> -48.6° in H<sub>2</sub>O; *hydriodide*, m.p. 185—188°\* (decomp.), [ $\alpha$ ]<sub>D</sub> -48.7° in H<sub>2</sub>O]; *heterodihydro- $\psi$ -codeine*, m.p. 235—237°\*, sublimes at 175°/high vac., [ $\alpha$ ]<sub>D</sub><sup>25</sup> -83.4° in EtOH (*hydrobromide*, m.p. 256—258°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -55.4° in H<sub>2</sub>O; *hydriodide*, m.p. 185—187°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -52.8° in H<sub>2</sub>O); *heteroethyl- $\gamma$ -isomorphine*, m.p. 215—220°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -43.5° in MeOH [*hydrochloride* (+2H<sub>2</sub>O), m.p. 287—290°\* (decomp.), [ $\alpha$ ]<sub>D</sub> -30.5° in H<sub>2</sub>O; *hydriodide* (+H<sub>2</sub>O), m.p. 276—277°\* (decomp.), [ $\alpha$ ]<sub>D</sub><sup>25</sup> -23.2° in H<sub>2</sub>O]; *heteroethylidihydro- $\gamma$ -isomorphine*, m.p. 220—223°\*, sublimes at 175°/high vac., [ $\alpha$ ]<sub>D</sub><sup>25</sup> -20.2° in EtOH (*hydriodide*, m.p. 277—281°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -9.1° in H<sub>2</sub>O; *methiodide*, m.p. 250—252°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -7.2° in H<sub>2</sub>O); *benzylmethylo-morphine* (*benzylmorphine alcoholic Me ether*), b.p. 180°/high vac. (*hydrochloride*, m.p. 233—236°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -88.9° in H<sub>2</sub>O; *H sulphate*, m.p. 247—249°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -90.1° in H<sub>2</sub>O; *methiodide*, m.p. 155—157°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -75.8° in EtOH); *benzylmethyldihydromorphine*, b.p. 210°/high vac., [ $\alpha$ ]<sub>D</sub><sup>25</sup> -89.1° in EtOH (*methiodide*, m.p. 155—157°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -54.60° in H<sub>2</sub>O), prepared by benzylation of heterocodeine; *benzylidihydrodeoxymorphine-D* (*hydrochloride*, m.p. 249°\*, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -34.4° in EtOH; *hydrobromide*, m.p. 226—227°\*, [ $\alpha$ ]<sub>D</sub> -29.8° in EtOH; *perchlorate*, m.p. 223—224°\*, [ $\alpha$ ]<sub>D</sub><sup>24</sup> -51.5° in EtOH; *methiodide*, decomp. about 70°, [ $\alpha$ ]<sub>D</sub> -25.8° in MeOH). *Benzylmorphine N-oxide* has m.p. 236—238°, [ $\alpha$ ]<sub>D</sub><sup>25</sup> -53.2° in EtOH. H. G. M.

**Preparation of apocodeine and its hydrochloride.** K. FOLKERS (J. Amer. Chem. Soc., 1936, 58, 1814—1815).—*apoCodeine* (+EtOH), m.p. 104.5—106.5° (decomp.), [ $\alpha$ ]<sub>D</sub> -90° in EtOH, m.p. (EtOH-free) 122.5—124.5° [*hydrochloride*, decomp. 260—263° (softens from 140°)], is prepared by a modification of Knorr and Roth's method (A., 1907, i, 790, where it is designated  $\psi$ -apocodeine). H. B.

**"Methoxyoxypalmitine."** N. N. CHOPRA and J. N. RÂY (J. Indian Chem. Soc., 1936, 13, 478—481).—2-Keto-4 : 5 : 6-trimethoxy-1 : 2-dihydroisobenzofuran-1-carboxylic acid (prep. from gallic acid Me<sub>3</sub> ether and chloral), +H<sub>2</sub>O, m.p. 147°, gives the  $\beta$ -3' : 4'-dimethoxyphenylethylamide, m.p. 154°, and thence (POCl<sub>3</sub>) 6 : 7-dimethoxy-1-4 : 5 : 6-trimethoxyphthalido- $\alpha$ -3 : 4-dihydroisoquinoline (I), reduced by Zn dust-AcOH to "methoxyoxypalmitine" (II), m.p. 170°.

$\beta$ -2 : 3 : 4-Trimethoxyphenylethylamine (from the propionamide and NaOCl) (*oxalate*, m.p. 185°) was condensed with meconinecarboxylic acid, but did not lead to an isoquinone derivative.

R. S. C.

**Curare alkaloids. II. Tubocurarine and bebeerine.** H. KING (J.C.S., 1936, 1276—1279).—Oxidation (KMnO<sub>4</sub>) of *O*-methylbebeerilene gives a mixture of 5 : 6 : 4'-tricarboxy-2 : 3-dimethoxydiphenyl ether (+2H<sub>2</sub>O), m.p. 207° (efferv.) (solidifies and remelts 245°), which is identical with the acid obtained by Faltis from isobebeerine (A., 1922, i, 570), 4 : 5 : 5'-tricarboxy-2 : 2'-dimethoxydiphenyl ether (+2H<sub>2</sub>O), m.p. 257—258° (efferv.) or (+2.5H<sub>2</sub>O) m.p. 145—150° (efferv.), remelts at 262—264° (decarboxylated to 2 : 2'-dimethoxydiphenyl ether), and an acid, C<sub>34</sub>H<sub>30</sub>O<sub>16</sub>·2H<sub>2</sub>O, m.p. 283—284°. The latter acid is an intermediate product of oxidation. The results support the structure for bebeerine proposed by Spath and Kuffner (A., 1934, 312). F. R. S.

**Occurrence of solanidine in sprouting potatoes.** G. R. CLEMO, W. MCG. MORGAN, and R. RAPER (J.C.S., 1936, 1299—1300).—The fresh shoots of different varieties of potato yield 0.04% of solanidine (I). It is suggested that (I) is represented as shown and not as suggested by Soltys and Wallenfels (this vol., 742).

F. R. S.

**Action of bromacetates on some alkaloids.** L. ESPIL and G. MANDILLON (Compt. rend., 1936, 202, 2177—2179).—Alkaloids containing :NH react with CH<sub>2</sub>Br·CO<sub>2</sub>Na liberating HBr to form a complex of reduced toxicity; e.g., strychnine is 200 times as toxic as its complex. F. N. W.

**Compounds of copper salts with tertiary arsines.** G. J. BURROWS and E. P. SANFORD (J. Proc. Roy. Soc. New South Wales, 1936, 69, 182—189).—Cu<sup>I</sup> or Cu<sup>II</sup> salts give the Cu<sup>I</sup> co-ordination compounds, CuI,AsPhMe<sub>3</sub>, m.p. 127°, CuI,2AsPhMe<sub>3</sub>, m.p. 94°, CuCl,2AsPhMe<sub>3</sub>, m.p. 127°, CuBr,AsPhMe<sub>3</sub>, m.p. 106°, CuNO<sub>3</sub>,AsPh<sub>2</sub>Me, m.p. 107°, CuBr,AsPh<sub>2</sub>Me, m.p. 133°, and CuCl,AsPh<sub>2</sub>Me, m.p. 116°. These are insol. in H<sub>2</sub>O, sol. in org. solvents, and have approx. normal mol. wts., but are not very stable in solution, giving Cu<sub>2</sub>O with NaOH and liberating Cu halides

when boiled for a long time. They are colourless, but slowly become blue in  $O_2$ . With excess of the arsine and  $Cu^{II}$  salts the following insol. mixed  $Cu^I-Cu^{II}$  compounds are obtained:  $Cu[Br_3Cu(AsPh_2Me)_3]$ , m.p.  $202^\circ$ , and  $Cu[Cl_3Cu(AsPh_2Me)_3]$ , blue (I) and brown (II) forms. These formulæ are uncertain, but account for the existence of (I) and (II) as stereoisomerides. (I) slowly passes into (II); they are identical at the m.p.  $245^\circ$  (green liquid) and with NaOH both give  $Cu_2O$ . R. S. C.

**Auxo-enoid systems. I. Colour of nitro-diphenylaminoarsinic acids containing complementary auxochromes.** V. A. ISMAILSKI and A. M. SIMONOV (Bull. Soc. chim., 1936, [v], 3, 1540—1545).—A system,  $CR:C:C$  or  $m$ - or  $p$ - $C_6H_4R$ , in which R is an auxochrome, is termed auxo-enoid. The colour of 3-nitro-4-anilinophenylarsinic acid (I) is due to interaction ("auxo-state") of the NH and  $NO_2$ , the NH assuming onium properties ("functioning as an onium perichrome") and being termed the "principal auxochrome" (or "principal auxo"). If an auxochrome, OH, NHAc, OR, or  $NH_2 \cdot C_6H_4$ , is present in the (previously) unsubstituted Ph of (I), it is termed a "complementary auxochrome"; it has a bathochromic effect if in the  $p$ -position, since it then reinforces the onium properties of the principal auxochrome by inductive forces; if in the  $m$ -position, its inductive effect opposes the onium properties and causes a lessening of colour. This interpretation is generalised for any auxo-enoid system attached to any principal auxochrome. It accounts for the bathochromic effect of introducing  $p$ -OMe into Variamine B. R. S. C.

**Reactivity of nuclear chlorine in the isomeric 1:2- and 2:1-chloronaphthalenearsinic acids.** G. W. BOWERS and C. S. HAMILTON (J. Amer. Chem. Soc., 1936, 58, 1573—1575).—1:2- $NH_2 \cdot C_{10}H_6 \cdot AsO_3H_2$  is converted (Sandmeyer) into 1-chloronaphthalene-2-arsinic acid (I), m.p.  $317^\circ$ , which with ArOH, anhyd.  $K_2CO_3$ , and a little Cu foil in  $PhNO_2$  gives 1-phenoxy-, m.p.  $322^\circ$ , and 1-o-tolyloxy-, m.p.  $181^\circ$ , naphthalene-2-arsinic acids, which are dehydrated by boiling AcOH to  $\alpha$ -benzophenoxarsinic acid, m.p.  $319^\circ$  (cf. Aeschlimann, A., 1925, i, 706), and its 11-Me derivative, m.p.  $177^\circ$ , respectively. 2:1- $C_{10}H_6Cl \cdot NO_2$  is reduced [ $H_2$  (40 lb.), Raney Ni, 95% EtOH] to 2:1- $C_{10}H_6Cl \cdot NH_2$ , converted (Bart) into 2-chloronaphthalene-1-arsinic acid (II), m.p.  $296^\circ$ , and thence (as above) into 2-phenoxy-, m.p.  $211^\circ$  (partly), re-solidifying with m.p.  $295^\circ$ , 2-o-, m.p.  $295^\circ$ , and -p-, m.p.  $225^\circ$  (partly), re-solidifying with m.p.  $273^\circ$ , -tolylloxy-, and 2-o-, m.p.  $230-231^\circ$ , and -p-, m.p.  $217-219^\circ$ , -chlorophenoxy-naphthalene-1-arsinic acids, which are dehydrated (AcOH) to  $\gamma$ -benzophenoxarsinic acid, m.p.  $278-280^\circ$ , and its 8-Me, m.p.  $205^\circ$  (partly), re-solidifying with m.p.  $270^\circ$ , 10-Me, m.p.  $215-217^\circ$ , 8-Cl-, m.p.  $216-218^\circ$ , and 10-Cl-, m.p.  $214^\circ$ , derivatives, respectively. (I) and (II) do not react with  $NH_2Ph$ ,  $NH_2Alk$ , or  $AlkOH$ ; the Cl is thus less reactive than in the corresponding  $C_6H_6$  derivatives (cf. A., 1931, 1173). H. B.

**Bismuth derivatives of diphenyl.** D. E. WORRALL (J. Amer. Chem. Soc., 1936, 58, 1820—1821).— $p$ - $C_6H_4Ph \cdot MgBr$  and  $BiCl_3$  give *Bi tri-p-diphenyl*l,

m.p.  $182-183^\circ$  [dichloride, m.p.  $198-200^\circ$  (decomp.), converted ( $EtOH-AgNO_3$  in  $COMe_2$ ) into the dinitrate, decomp. about  $162^\circ$ ; dibromide, m.p. indef. with decomp.], which with  $BiCl_3$  in  $Et_2O$  affords *Bi di-p-diphenyl chloride*, m.p. indef. H. B.

**Carbazole. I. Selective metalation.** H. GILMAN and R. H. KIRBY (J. Org. Chem., 1936, 1, 146—153).—Carbazole when refluxed with  $LiBu^a$  in  $Et_2O$  and then treated with  $CO_2$  gives carbazole-1-carboxylic acid. Similarly 9-ethylcarbazole (I) gives its 1-carboxylic acid. Metalation occurs to a slight extent with  $CaPhI$ , but not with  $MgEtBr$ . (I) with  $Hg(OAc)_2-EtOH-AcOH$  or when fused with  $Hg(OAc)_2$  gives 9-ethyl-3-acetoxymercuricarbazole (II), m.p.  $156^\circ$ , and a dimercurial (III), m.p.  $242^\circ$ . (II) gives (I) with  $EtOH-HCl$ , and the 2-iodo- (IV) and 2-chloro-9-ethylcarbazoles when treated, respectively, with  $KI-I$  and with  $CaCl_2$ . (II) with  $N_2H_4 \cdot H_2O$  gives bis-(9-ethylcarbazyl-3-)mercury, m.p.  $217^\circ$ , which with  $Li-Et_2O$  followed by  $CO_2$  gives 9-ethylcarbazole-3-carboxylic acid, m.p.  $226^\circ$ , also obtained (Grignard) from (IV), from (I) by bromination followed by carbonation of the corresponding Li compound, and by ethylation of Et carbazole-3-carboxylate, followed by hydrolysis. (III) with  $KI-I$  gives 3:6-di-iodo-9-ethylcarbazole, also obtained by direct iodination of (I). This with  $Cu_2(CN)_2$ ,  $KCN$ ,  $H_2O$ , and  $EtOH$  (sealed tube,  $230^\circ$ , 20 hr.) gives 9-ethylcarbazole-3:6-dicarboxylic acid, m.p.  $>320^\circ$  ( $Me_2$  ester, m.p.  $187^\circ$ ), also obtained by oxidation with  $K_2Fe(CN)_6-KOH-H_2O$  of 3:6-diacetyl-9-ethylcarbazole, m.p.  $182^\circ$ , prepared by ethylating 3:6-diacetylcarbazole (A., 1935, 990). This establishes the positions of Hg in (III). H. G. M.

**Magnetochemical investigations of organic substances. VIII. Metal ketyls of 4-pyrones.** E. MÜLLER and F. TESCHNER (Annalen, 1936, 525, 1—13).—Magnetic investigations of the K derivatives of 2:6-dimethylpyrone, 2-methylchromone, and 2:3:6:7-dibenzoanthone exclude the possibility of formulating them as free radicals. Pfeiffer's formulation  $R_2C:O \cdots K$  is excluded by chemical evidence. It is therefore necessary to double the formula, thus leading to a choice between  $RK \cdot OK + RO$  and  $[R(OK)]_2$  ( $R=O < \begin{smallmatrix} CMc:CH \\ CMc:CH \end{smallmatrix} > C$ ). Since the action of MeI leads to a very unstable, reddish-brown perchlorate instead of to Baeyer's colourless trimethylpyrylium perchlorate the latter formulation is advocated with reserve. The magnetic behaviour of the K derivative of xanthone excludes the formulations of Pfeiffer, Schlenk, and Weitz and, combined with analytical behaviour, suggests that it is a quinhydrone-like, complex mol. mixture of eight xanthone mols. or an equilibrium between a pinacoid and a radical form. H. W.

**Cross linking formation in keratins.** J. B. SPEAKMAN (Nature, 1936, 138, 327).—A discussion of the nature of the linkings responsible for the contraction of wool when treated by various reagents. Permanent setting is explained by the formation of  $\cdot S \cdot NH \cdot$  rather than  $\cdot N \cdot CH \cdot$  linkings. L. S. T.

**New electrochemical method of preparing proteins at the isoelectric point.** J. SWYNGEDAUF

(Compt. rend., 1936, 203, 54—57).—The electrolytic method previously described (cf. A., 1934, 961) has been successfully applied to the treatment of ovalbumin and casein. With hæmoglobin, however, the  $p_H$  of the high-resistance zone is 3.4 whereas the isoelectric point is about 6.8. C. R. H.

**Polysaccharoproteins.**—See this vol., 1404.

**Handling and weighing absorption tubes in micro-determinations of carbon and hydrogen.** D. F. HAYMAN (Ind. Eng. Chem. [Anal.], 1936, 8, 342—343).—The balance room is kept at const. temp., Pregl absorption tubes are used, special precautions are taken when wiping the tubes, and freedom from dust and lint is ensured by examining the tubes visually in a narrow beam of light against a dark ground. The tubes are weighed immediately after wiping and errors due to electrostatic effects are eliminated by maintaining the R.H. of the laboratory at  $<45\%$ . S. C.

**Micro-determination of carbon and hydrogen in compounds containing arsenic, antimony, tin, bismuth, and phosphorus.** F. C. SILBERT and W. R. KIRNER (Ind. Eng. Chem. [Anal.], 1936, 8, 353—355).—Satisfactory results are obtained by replacing part of the Pregl universal filling with Pt gauze and a mixture of Pt gauze and  $Pb_3O_4$ . S. C.

**Organic micro-analysis. I. Nitrogen by Dumas' method.** R. T. MILNER and M. S. SHERMAN (Ind. Eng. Chem. [Anal.], 1936, 8, 331—332).—A simplified all glass micro-combustion apparatus is described. The nitrometer is closed by a ground conical stopper instead of the usual stopcock. A simply constructed, hinged electrical heating element is described and the various corrections to be applied are measured and discussed. S. C.

**Formation of nitric acid during the combustion of organic nitrogen compounds in the calorimetric bomb.** A. J. PETRICK (J. Chem. Met. Soc. S. Africa, 1936, 37, 1—3).—Org. compounds containing N when burned in  $O_2$  at 30 atm. afford  $HNO_3$ , determined by titration. In S-containing compounds allowance is made for the  $H_2SO_4$  formed, which is determined as  $BaSO_4$ . The  $HNO_3$  formed accounts for 1.41—11.14% of the N in the compound; high vals. are obtained in the presence of S. J. L. D.

**Nesslerisation applied directly to a macro-Kjeldahl nitrogen determination.** S. MORGULIS and H. C. SPENCER (Ind. Eng. Chem. [Anal.], 1936, 8, 330).—The wet sample of tissue is weighed on a tared piece of Sn foil folded so as to prevent loss of  $H_2O$  and dropped into  $H_2SO_4$  used for the Kjeldahl determination. After digestion the solution is bleached with  $H_2O_2$ , diluted, the Sn ppt. allowed to settle, and  $NH_3$  determined in the clear supernatant liquid by means of Nessler's reagent. S. C.

**Modification of micro-Zeisel apparatus for determination of methoxyl and ethoxyl groups.** J. J. CHINOY (Analyst, 1936, 61, 602—603). J. S. A.

**Microchemical determination of butyric acid.** L. KLING (Mikrochem., 1936, 19, 187—189; cf. A., 1934, 1331).— $PrCO_2H$  is oxidised by  $H_2O_2$  in presence

of Fe to  $COMe_3$ , which is distilled directly into the Scott-Wilson  $Hg(CN)_2$ - $AgNO_3$  reagent. J. S. A.

**Determination of lactic acid.**—See this vol. 1436.

**New reagents for the carbonyl group, their application to the extraction of ketonic substances and the microchemical characterisation of aldehydes and ketones.** A. GIRARD and G. SANDULESCO (Helv. Chim. Acta, 1936, 19, 1095—1107).—The prep. of *trimethylcarbohydrazidomethylammonium chloride*,  $NMe_3Cl \cdot CH_2 \cdot CO \cdot NH \cdot NH_2$  (I) ("reagent T"), hygroscopic needles, m.p.  $192^\circ$  (slight decomp.), from  $NMe_3$ ,  $CH_2Cl \cdot CO_2Et$ , and  $N_2H_4 \cdot H_2O$  in boiling EtOH and of *carbohydrazidomethylpyridinium chloride* (II) (reagent P), decomp.  $> 200^\circ$  (corr.), is described. In neutral solution they react very slowly with CO compounds, and generally a large excess of reagent is used in EtOH containing 10% of AcOH; action is then complete in 20—30 min. at the b.p. of the solution. The hydrazones thus produced are cryst. compounds sol. in  $H_2O$  and alcohols, insol. in org. media without OH. In approx. neutral solution they are relatively stable, whereas at  $p_H < 6$  those of the ketones are rapidly decomposed and those of aldehydes are stable. Separation of aldehyde from ketone is therefore possible by treatment of the mixture with (I) or (II) and of the aq. solution of the product with  $H_2SO_4$  (50 g. per litre); after 1 hr. the liberated ketone is extracted with  $Et_2O$ . In practice, (I) and (II) are not suitable for the study of aldehydes. For the isolation of the ketonic fraction of natural materials the latter is dissolved in abs. EtOH and treated with (I) or (II). The resulting solution is poured into ice water containing sufficient  $Na_2CO_3$  to neutralise 90% of the AcOH and then extracted with  $Et_2O$ . The aq. solution is made 0.5—1.0N with HCl or  $H_2SO_4$  and kept for 1 hr., after which the ketones are extracted with  $Et_2O$ . Emulsification is avoided by suitable use of EtOH or by replacing  $H_2O$  by  $(\cdot CH_2 \cdot OH)_2$ . Possibilities of fractionation are opened up by the very varying rates with which (I) and (II) react with ketones and the (non-correlated) differing rates of hydrolysis of the compounds formed. The hydrazones show the general reactions of alkaloidal salts and their presence in aq. solution if derived from (I), and their presence is readily detected by the formation of a flocculent orange ppt. on addition of a solution of  $BiI_3$  (1 g.), KI (10 g.), and conc. HCl (5 c.c.) in  $H_2O$  (to 100 c.c.) or, preferably, by their behaviour towards a solution of  $HgI_2$  (5 g.) and KI (10 g.) in  $H_2O$  (100 c.c.). The extraction of oestrone from urine of pregnancy and the purification of MeOH from traces of  $COMe_3$  are described. H. W.

**Micro-determination of fructose in presence of glucose.** S. M. STREPKOV (Biochem. Z., 1936, 287, 33—34).—The method depends on the fact that fructose (I) is completely oxidised in 2.5 hr. at  $60^\circ$  by an alkaline  $Na_2HPO_4$ - $K_3Fe(CN)_6$  solution whilst glucose (II) is not attacked. (I) is then determined by iodometric titration of the  $K_4Fe(CN)_6$  formed. Tables for reading off the results are given both for (I) in aq. solution and in presence of (II). P. W. C.

**Determination of creatinine.** A. BOLLIGER (J. Proc. Roy. Soc. New South Wales, 1936, 69,

224—227).—The purple colour given by creatinine (I) and alkaline 3:5-(NO<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·CO<sub>2</sub>H is used as a qual. and quant. test. At 0° the colour given by the reagent alone does not interfere for the 15—25 min. required for development of max. intensity by (I). Purified acid gives better results. The test is better than that of Jaffe. R. S. C.

Action of copper salts on benzidine in presence of halides and thiocyanates and a new sensitive test for copper. L. KUHLBERG (Mikrochem., 1936, 20, 153—160).—Benzidine gives a ppt. with Cu<sup>++</sup> the colour of which varies with the anion present. Br<sup>-</sup> and CNS<sup>-</sup> form benzidine-blue. Cl<sup>-</sup> does not effect the benzidine reaction but produces *o*-tolidine-blue. The mechanism is discussed in terms of the potential Cu<sup>++</sup>/Cu<sup>+</sup> and the solubility product of the Cu<sup>+</sup> salt. A reagent containing 0.1 g. of *o*-tolidine +0.5 g. of NH<sub>4</sub>CNS in 5 c.c. of COMe<sub>2</sub> is recommended for Cu. Strongly oxidising salts must first be reduced with Bi-Hg. R. S.

Sensitive colour reaction of phenol with "fast-red salt B," and its use as drop reaction. Y. KONDO (Mikrochem., 1936, 19, 214—221).—PhOH gives with 0.05—0.1% aq. "fast-red salt B" in presence of Li<sub>2</sub>CO<sub>3</sub> a very sensitive red to orange coloration; limit 10<sup>-8</sup> g. of PhOH. Other (polyhydric) phenols give colorations of different shades. J. S. A.

Application of chloroamine in organic analysis. L. VŠETĚČKA (Časopis českoslov. Lék., 1935, 15, 51—56; Chem. Zentr., 1935, ii, 3954).—1 mol. of uric acid requires 2 mols of NH<sub>2</sub>Cl for oxidation in alkaline solution. A volumetric method based on this reaction is described. H. N. R.

Colorimetric determination of uric acid (Folin).—See this vol. 1436.

Identification of yohimbine. M. L. SHANER and M. L. WILLARD (Mikrochem., 1936, 19, 222—226).—Cryst. ppts. given by yohimbine with metallic chlorides and with the usual alkaloid reagents are described. Identification is best effected through the acid salts, for which microscopic and crystallographic data are given. J. S. A.

The biuret reaction. II. Metal-biuret compounds. III. Protein compounds of copper, nickel, and cobalt. H. JESSERER (Biochem. Z., 1936, 287, 71—83, 84—87; cf. this vol. 1007).—In the complexes of Cu with the following org. bases, 1 atom of Cu is associated with 2 mols. of biuret (I), oxamide (II), or malonamide (III). At the same wt. concn. the strength of colour with (I) is the same as with caseinogen (IV), but the complex with (I) contains three times as much Cu as with (IV). The colour with (I), as with (IV), consists of red and blue components; the latter on long keeping separates, the red component remaining and then containing 1 atom of Cu to 4 mols. of (I). The formulae of the compounds are discussed. Complexes of (I) in alkaline solution with Ni and Co are prepared in which 1 atom of metal is associated with 3 and 6 mols. of (I), respectively. (II) and (III) give complexes containing 1 atom of Ni to 3 mols. of base.

III [with F. LIEBEN]. Clupein ester hydrochloride gives a complex containing 4 Cu per mol. When the violet Cu-(IV) complex is dialysed, the blue colour separates without decomp. Ni- and Co-(IV) complexes decompose on dialysis. Zn separates the whole of the Cu from the Cu-(IV) complex. No difference in valency was detected in the Cu of the red and blue components. In the Ni- and Co-(IV) complexes 1 atom of Ni replaces 2 Cu and 1 atom of Co replaces 3 of Cu. P. W. C.

## Biochemistry.

Gaseous metabolism during controlled restriction of respiration. I. In men with normal hearts. II. In men during dyspnoea. A. LUBLIN (Arch. exp. Path. Pharm., 1936, 182, 427—436, 437—443).—I. Restricted respiration increases the vol. of expired CO<sub>2</sub> and decreases that of utilised O<sub>2</sub> so that the R.Q. increases to vals. >1.

II. Hyperventilation occurs, the utilised O<sub>2</sub> tending to decrease and the R.Q. to increase. F. O. H.

Effect of oxygen lack, variations in the carbon dioxide content of the inspired air, and hyperpnoea on visual intensity discrimination. E. GELLHORN (Amer. J. Physiol., 1936, 115, 679—684). R. N. C.

Respiratory ventilation in the cockroach in air, in carbon dioxide, and in nicotine atmospheres. R. L. KITCHEL and W. M. HOSKINS (J. Econ. Entom., 1935, 28, 924—933). A. G. P.

Rate of elimination of dissolved nitrogen in man in relation to the fat and water content of the body. A. R. BEHNKE, R. M. THOMSON, and L. A. SHAW (Amer. J. Physiol., 1935, 114, 137—

146).—O<sub>2</sub> inhalation results in elimination of dissolved body N<sub>2</sub> in equilibrium with pulmonary N<sub>2</sub>, about 98% being removed in 6 hr. in a young well-developed man. Most of the N<sub>2</sub> is stored in the body-H<sub>2</sub>O. The N<sub>2</sub> content of a well-nourished dog is approx. the same as that of man. The N<sub>2</sub> elimination curve is exponential. During decompression of divers exposed to high pressures for short periods, the body-fats act as N<sub>2</sub>-absorbents and prevent bubble formation. R. N. C.

Position of the oxygen dissociation curve of human blood at high altitudes. A. KEYS, F. G. HALL, and E. S. G. BARRON (Amer. J. Physiol., 1936, 115, 292—307).—At const. *p*<sub>H</sub> of the cells, the affinity of haemoglobin for O<sub>2</sub> tends to decrease at high altitudes. The dissociation curve is displaced to the left of the sea-level curve up to 14,000 ft.; above this level the curve is displaced increasingly to the right. Curves for arterial blood during work are similar to those obtained at rest. The curves for men accustomed to altitudes up to 5340 m. are within the normal limits for men at sea-level. R. N. C.

**Effect of altitude on the affinity of hæmoglobin for oxygen.** F. G. HALL (J. Biol. Chem., 1936, 115, 485—490; cf. preceding abstract).—The  $O_2$  affinity of human hæmoglobin, determined spectrographically after hæmolysis and dilution, remains unchanged with change in altitude between sea-level and 20,000 ft. F. A. A.

**Gaseous equilibria in the lungs at high altitudes.** D. B. DILL, E. H. CHRISTENSEN, and H. T. EDWARDS (Amer. J. Physiol., 1936, 115, 530—538).—The partial pressure of  $O_2$  in arterial blood at high altitudes is approx. equal to that of alveolar air.  $O_2$  saturation of arterial blood does not necessarily increase during acclimatisation. R. N. C.

**Arterialisation of blood. V. Possibility of influencing gaseous exchange between alveoli and blood.** K. KRAMER and H. SARRE (Z. Biol., 1936, 97, 329—342; cf. A., 1935, 371, 878).—Increase in depth of respiration due to lobeline (I) decreases the difference in  $O_2$  tension between alveoli and arterial blood. The initial difference in  $O_2$  tension between alveoli and the pulmonary venous blood is, however, of importance; when high, (I) increases the alveolar tension and diminishes the  $O_2$ -saturation of the venous blood, resulting in an increased difference between alveoli and arterial blood. Adrenaline increases the inflow of blood and considerably displaces the gaseous exchange. The bearing of these and previous data on  $O_2$ -uptake is discussed. F. O. H.

**Absorption of water from the small intestine at various degrees of anoxæmia.** E. J. VAN LIERE, N. A. DAVID, and D. H. LOUGH (Amer. J. Physiol., 1936, 115, 239—244).—Absorption is increased, an apparent optimum occurring when the blood- $O_2$  is approx. 10%. R. N. C.

**Iodophilic substance of leucocytes.** A. GIRARDIN (Jahrb. Kinderheilk., 1935, 145, 140—166; Chem. Zentr., 1935, ii, 3790).—Iodophilic granules of neutrophile leucocytes are shown by treatment of moist blood with I vapour. The normal proportion (20%) is increased in certain infectious diseases, after a meal in sucklings, and in certain metabolic disturbances in children. A. G. P.

**Glycolytic activity of blood-corpuscles of normal and diabetic persons.** A. CURATOLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 262—263).—The glycolytic activity of washed corpuscles from diabetic blood is < normal. F. O. H.

***In-vitro* and *in-vivo* action of insulin on glycolysis of blood-corpuscles.** A. CURATOLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 264—265).—The glycolysis of corpuscles of non-diabetic persons is unaffected, whilst that of corpuscles of diabetics is diminished, by injection or *in-vitro* addition of insulin. F. O. H.

**Products of blood-glycolysis.** R. INDOVINA (Boll. Soc. ital. Biol. sperim., 1936, 11, 267—268).—The discrepancy between glucose metabolised and lactic acid (insufficiently) formed by suspension of normal corpuscles in glucose-Ringer's solution at 37° is at least partly due to formation of acid-hydrolysable complexes. F. O. H.

**Formation of a phosphorylated compound during *in-vitro* glycolysis.** R. INDOVINA (Boll. Soc. ital. Biol. sperim., 1936, 11, 268—269).—Incubation of suspensions of normal blood-corpuscles in glucose-Ringer's solution at 37° produces a complex which on acid hydrolysis yields inorg. P. F. O. H.

**Electric impedance of injured and sensitised red blood-corpuscles.** H. J. CURTIS (J. Gen. Physiol., 1936, 20, 105—109).—No change in the electrical properties was detected in suspensions injured or sensitised up to the point of hæmolysis. H. G. R.

**Properties of red cell surfaces influencing rouleau formation.** H. L. WHITE and B. MONAGHAN (Amer. J. Physiol., 1936, 115, 31—37).—The sinking velocity of red cells of different species in 1% gelatin  $\propto$  their electrophoretic mobilities at  $pH$  7.4 and inversely  $\propto$  the isoelectric point of the ghosts. Stability in gelatin depends on the free surface energy at the cell-medium interface, which is largely determined by the degree of hydration, and, in turn, by the chemical structure of the cell surface. The surface probably consists of a combination of protein and lipin, the proportion varying with the species. The isoelectric points of washed dog, ox, and rabbit ghosts are 2.7, 3.4, and 4.3, respectively, and are a closer approach to the isoelectric points of intact cells than can be obtained by working with intact cells. R. N. C.

**Changes in the permeability to glucose of red corpuscles in shed blood.** J. M. D. OLMSTED (Amer. J. Physiol., 1936, 114, 488—490).—Glucose increases rapidly in human corpuscles after the blood has been drawn. The rate of increase in rabbit corpuscles is considerably less, whilst pigs' corpuscles remain impermeable. R. N. C.

**Effect of hæmorrhage on hæmoglobin content and distribution in erythrocytes.** A. G. ZOCCOLI and A. DE NIEDERHAUSEN (Boll. Soc. ital. Biol. sperim., 1936, 11, 317—318).—Hæmorrhage of 20% of the circulating blood increases the size and hæmoglobin (I) content of the erythrocytes; with severe hæmorrhage the content of (I) per unit vol. and superficial area of the erythrocytes increases. F. O. H.

**Hæmoglobin and iron of the blood. I. Determination of the total iron of blood.** H. I. COOMBS (Biochem. J., 1936, 30, 1588—1591).—The sample (0.1 ml.) is ashed with  $H_2SO_4$  and  $HNO_3$ , and dipyrityl, glucose, and NaOAc are added. A pink colour develops during 5 min. at 100°; this is stable, and unaffected by Cu or  $PO_4'''$ . F. A. A.

**Availability of copper from various sources as a supplement to iron in hæmoglobin formation.** M. O. SCHULTZE, C. A. ELVEHJEM, and E. B. HART (J. Biol. Chem., 1936, 115, 453—457).—The Cu of wheat germ, lucerne, brewers' yeast, pig's heart and liver, cysteine  $Cu^I$  mercaptide (A., 1933, 382), and Cu aspartate, citrate, nucleinate, and pyrophosphate, in amounts equiv. to 0.01 mg. daily, is readily utilised by anæmic rats to supplement Fe (0.5 mg. daily) for hæmoglobin formation. F. A. A.

**Hæmoglobin regulation in chickens. I. W. HARMON** (Poultry Sci., 1936, 15, 53—62).—The hæmoglobin (I) level was highest at hatching and at maturity and lowest at 2 weeks of age. Sexual differences in level were not apparent until 8 weeks of age, and in mature birds were in the order, cocks > capons > hens. A splenic reserve of (I) occurs in capons, hens, and 10-week cockerels and pullets, but not in cocks or broody hens. Vals. declined during egg production, but were higher in heavy than in poor layers in corresponding stages. Onset of broodiness and cessation of laying were marked by a rapid increase in (I) vals. A. G. P.

**Ultra-violet absorption spectrum of hæmoglobin. G. A. ADAMS** (Nature, 1936, 138, 368).—Addition of stromatin (I) causes the 410 m $\mu$  absorption band of hæmoglobin (II) to disappear. In red blood (II) may be combined with (I), and the combination may be responsible for the absence of this band in corpuscular (II) (cf. A., 1934, 673). Cholesterol, lecithin, and glutathione have not this effect. L. S. T.

**Methylene-blue and hæmoglobin derivatives in asphyxial poisoning. M. M. BROOKS** (Amer. J. Physiol., 1935, 114, 160—178).—KCN stabilises the colour of oxyhæmoglobin by forming cyanohæmoglobin, which has the same spectrum; it attaches itself to the Fe ion of hæmoglobin (I) or methæmoglobin (II). Methylene-blue does not form (II) in the blood-stream or defibrinated blood, with or without KCN; it acts as a catalyst rather than as a (I) producer. Reducing agents in the blood-stream, including glucose, prevent (II) formation. NaNO<sub>2</sub> produces (II) when in sufficient concn. to overcome the reducing capacity of the blood. Cryst. derivatives of (I) do not give the above results, owing to the absence of reducing agents. R. N. C.

**Plasma-protein regeneration after bleeding in the rat. W. C. CUTTING and R. D. CUTTER** (Amer. J. Physiol., 1935, 114, 204—206).—Total proteins recover their original val. 12 hr. after bleeding; the regeneration is decreased by injection of Indian ink. R. N. C.

**Crystallisation of serum-albumin from different species. M. GRINSTEIN** (Anal. Asoc. Quím. Argentina, 1936, 24, 11—18).—The cryst. form of serum-albumin from man differs from that from the guinea-pig, horse, mule, and ass, those from the last three species being indistinguishable from one another. F. R. G.

**Protein content of the serum of ungulates. A. URBAIN and R. CAHEN** (Compt. rend., 1936, 203, 277—279).—The total protein of sera of various species (both ruminants and non-ruminants) is similar to that of human serum, except that in sheep it is less, and in equidæ it is slightly higher. P. G. M.

**Determination of serum-proteins. K. PLOTNER** (Biochem. Z., 1936, 286, 429—434).—The mean sp. refraction of 22 samples of pathological human serum-protein was 0.00188, a val. agreeing with the accepted val. for horse serum (0.00187). Considerable changes in globulin content do not significantly change the val. P. W. C.

**Nephelometry of blood-proteins. III. Nature of the protein-sulphosalicylic acid turbidity reaction. Interrelationship of serum-proteins. K. PLOTNER** (Biochem. Z., 1936, 286, 279—284).—The sulphosalicylic acid turbidity val. of an albumin (I) solution on addition of small amounts of globulin (II) considerably decreases and, after reaching a min.,  $\propto$  the added (II). The results are explained by assuming that a mol. complex of (II) and (I) (1 : 2) is formed (cf. this vol. 1008). P. W. C.

**Simplification of micro-methods. I. Micro-determination of non-protein-nitrogen of blood. J. PUYAL and A. KUTZ** (Anal. Fís. Quím., 1934, 32, 742—747).—The blood is deproteinised by the Hagedorn method and the residual N determined by a micro-Kjeldahl method. The process is quicker and more accurate than that of Bang. L. A. O'N.

**Urate distribution in blood. J. H. TALBOTT and J. M. SHERMAN** (J. Biol. Chem., 1936, 115, 361—370).—The concn. of urate (I) in serum and cells agrees approx. with the Donnan law applied to blood. The (I) distribution ratio between cells and serum increases with acidity at approx. the same rate as the Cl' ratio. Oxygenation and reduction of blood containing added (I) change the distribution of (I) in the same way as Cl' and HCO<sub>3</sub>'. The max. concn. of serum-(I) observed was 1.63 milliequiv. per litre. E. M. W.

**Cholesterol. H. W. SOPER** (Amer. J. Digest. Dis. Nutrition, 1935, 2, 381—382).—A summary of recent investigations of blood-cholesterol and its influence on dietary habits. CH. ABS. (p)

**Fractionation of cholesterol in blood by precipitation as pyridine cholesteryl sulphate and cholesterol digitonide. J. J. DREKTER, A. E. SOBEL, and S. NATELSON** (J. Biol. Chem., 1936, 115, 391—399).—Determination of free cholesterol (I) after pptn. as C<sub>5</sub>H<sub>5</sub>N cholesteryl sulphate gives vals. of 6—10% as opposed to 25—35% after pptn. as (I) digitonide. The former method gives higher vals. for total (I). (I) may exist in serum in a "loosely-bound" form pptd. only by digitonin. In erythrocytes most of the (I) is "unbound," i.e., pptd. by either method. E. M. W.

**"Bound" sugar of the blood. I. Influence of protein-fat diets and relation to free blood-sugar. II. Influence of fasting and relation to free blood-sugar. Y. MATSUOKA** (J. Biochem. Japan, 1936, 23, 161—170, 171—179).—I. Fat-protein diets have little effect on the combined sugar (I) of dog's blood. With mixed carbohydrate diets, orally administered glucose produces a slight decrease which is enhanced by supplementing the diet with fat+protein but not with fat+protein+carbohydrate. High vals. of (I) are associated with low vals. of free sugar (II).

II. Fasting for 1 week has no effect, whilst fasting for 3 weeks slightly decreases (I). The increase in (I) due to carbohydrate ingestion after a week's fast is > that after 3 weeks' fast; continued ingestion results in a rapid return of (I) to normal vals. High levels of (I) are again associated with low vals. of (II). F. O. H.

**Influence of vagi and splanchnics on blood-sugar response to glucose administration.** M. AISNER, A. J. GORNEY, and M. S. SEGAL (Proc. Soc. Exp. Biol. Med., 1936, 34, 454—459).—The tolerance of dogs to glucose administered intravenously was not increased by vagotomy. Removal of one adrenal and denervation of the other resulted in a slight but probably insignificant increase in tolerance, whilst celiac ganglionectomy produced no additional effect.

W. O. K.

**Blood-sugar. II. Reduction values of tungstate and mercuric filtrates. Existence of a supposed glucose ester. I.** M. LORA TAMAYO (Anal. Fis. Quim., 1934, 32, 858—867).—Filtrates from blood deproteinised by the Folin-Wu method have a glucose (I) content (determined by the author's method; A., 1934, 793) > that of filtrates from Bierry and Moquet's reagent. The probable causes are discussed and it is shown that in presence of inorg.  $\text{PO}_4'''$ , (I) is carried down in the Hg ppt. F. R. G.

**Blood-phosphorus. V. Acid and enzymic hydrolysis of the acid-soluble organic phosphorus. Phosphoglycerate fraction.** E. WARWEG and G. STEARNS (J. Biol. Chem., 1936, 115, 567—581).—Acid-hydrolysis of filtrates of human blood deproteinised with  $\text{CCl}_3\cdot\text{CO}_2\text{H}$  is rapid for the first 10 min., the hexose diphosphate being rapidly and the  $\beta$ -glycerophosphate very slowly destroyed. The reaction slows down until after 12 hr. a const. slow rate (unimol. reaction) is attained, the acid-resistant substance being probably phosphoglycerate (I). The org. P is at first more readily hydrolysed by phosphatase at  $p_{\text{H}}$  8.8, but after 24 hr. the optimum shifts to 7.4, which is the same as that of (I) from pig's blood. The ester-P of adult blood consists of approx. 62—75% of (I)-P and 11.4% of  $\text{P}_2\text{O}_7'''$ -P.

H. G. R.

**Blood-sugar, inorganic phosphorus, and phosphatase activity following the intravenous injection of calcium salts.** A. CANTAROW, J. T. BRUNDAGE, and E. L. HOUSEL (Amer. J. Physiol., 1936, 115, 1—4).—Ca gluconate or levulate produces in the dog a rise of blood-protein, a rapid fall of sugar, a slower fall of inorg. P, and variable and insignificant changes in serum-phosphatase activity. R. N. C.

**Partition of serum-calcium.** J. DUCKWORTH and W. GODDEN (Biochem. J., 1936, 30, 1560—1566; cf. A., 1935, 385).—Determinations of  $\text{Ca}^{++}$ , ultrafilterable, non-ultrafilterable, protein-bound, and total Ca, inorg. P, and protein in the blood-serum of lambs on a basal diet supplemented with maize starch, and of these Ca fractions, inorg. P, and Mg in the serum of a cow after injection of large amounts of aq. Na citrate and in cow's blood *in vitro* after addition of aq. Na citrate indicate that K in the equation of Maclean *et al.* (Amer. J. Med. Sci., 1935, 189, 601) is too variable to aid in the study of Ca partition. The four Ca fractions found by adsorption on  $\text{BaSO}_4$  and ultrafiltration are real entities. W. McC.

**Partition of calcium and inorganic phosphorus in the blood-sera of horses.** P. B. PEARSON and H. R. CATCHPOLE (Amer. J. Physiol., 1936, 115, 90—93; cf. this vol., 497).—Inorg. P in the serum of Shetlands is > that in other species. There is no

correlation between total Ca and inorg. P, but significant correlation between total and diffusible Ca and inorg. P. R. N. C.

**Cataphoretic investigation of the state of copper in blood-serum.** B. EISLER, K. G. ROSDAHL, and H. THEORELL (Biochem. Z., 1936, 286, 435—438).—The total Cu of blood-serum is united with the serum-albumin. P. W. C.

**Photometric micro-determination of iron in blood.** G. BUCCIARDI (Boll. Soc. ital. Biol. speriment., 1936, 11, 316—317).—Blood is ashed, oxidised by  $\text{HNO}_3$ , heated with  $\text{H}_2\text{SO}_4\text{--HNO}_3$  followed by  $\text{H}_2\text{O}$ , and, after removal of  $\text{HNO}_3$  by urea,  $\text{Fe}^{+++}$  is determined by addition of  $\text{NH}_4\text{CNS}$  and photometric determination of extinction coeff. F. O. H.

**Regulation of the mineral composition of body-fluids in fishes.** A. DRILHON and E. A. PORA (Ann. Physiol. Physicochim. biol., 1936, 12, 139—168).—The osmotic pressure of the serum in the carp is normally > that of the surrounding  $\text{H}_2\text{O}$  but, if the salinity of the  $\text{H}_2\text{O}$  is increased by addition of sea- $\text{H}_2\text{O}$ , the internal osmotic pressure is unaltered until the f.p. depression of the external medium reaches  $-0.67^\circ$ . Above this val. the serum is at first hypotonic and equilibrium with more conc. solutions is associated with increase of Na, K, and Ca in the serum. The muscles and not the gills are the chief regulators of the composition of the internal medium. The proteins are stable and unaffected by changes in salinity of the ambient medium. NUTR. ABS. (m)

**Physical chemistry of fish blood.** A. DRILHON and G. FLORENCE (Bull. Soc. Chim. biol., 1936, 18, 1055—1073).—A study of the buffering power of the serum and the cataphoresis of the serum-proteins shows that during the adaptation of the eel with its protective mucus from fresh to sea- $\text{H}_2\text{O}$  there is a slow diminution in the alkaline reserve without any change in the protein equilibrium. Without the mucus, however, the change in alkaline reserve is rapid and a slight change in the protein equilibrium takes place. Substitution of aq. KCl for sea- $\text{H}_2\text{O}$  causes no change in the alkaline reserve, but a displacement of the isoelectric point of the serum-proteins. When the salt- $\text{H}_2\text{O}$  fish *Muræna* is placed in fresh  $\text{H}_2\text{O}$ , there is a displacement of the isoelectric point of the serum-proteins, although the fish is unaffected by a change to a greater degree of salinity. A. L.

**Determination of blood- $p_{\text{H}}$  by the glass electrode. IV. Potential drift of quinhydrone electrode applied to solutions of alkaline buffer, amino-acids, or proteins, or to plasma.** H. YOSHIMURA (J. Biochem. Japan, 1936, 23, 187—210; cf. A., 1935, 1143).—The potential drift is due to a chemical change in benzoquinone (I) producing acidic products to an extent dependent on temp., concn. of solution, and  $p_{\text{H}}$ . A secondary cause is autoxidation of quinol (II) to (I). Saturation of solutions of  $p_{\text{H}} > 5$  with (II) produces a slight acidification due to dissociation of (II). Determinations accurate to 0.02  $p_{\text{H}}$  are afforded by measurements taken within the following times: aq. buffer up to  $p_{\text{H}}$  8, 5 min.; aq.  $\text{NH}_2$ -acid or protein, 1 min.; plasma 30 sec. F. O. H.

**Validity of determinations of the  $p_H$  of whole blood at 38° with the glass electrode.** J. SENDROY, jun., T. SHEDLOVSKY, and D. BELCHER (J. Biol. Chem., 1936, 115, 529—542).—With citrate,  $PO_4'''$ , and  $HCO_3'-CO_3''$  buffers the  $p_H$  as determined by the Clark-Cullen (C) H electrode and MacInnes-Belcher glass electrodes A (A., 1933, 689) and B (thin membrane type) were consistent, but with reduced whole blood at various  $CO_2$  tensions, A deviated by a mean of  $-0.011$  from the val. given by C. When standardised with  $0.1N-HCl$ , B gave a val.  $0.02 <$  that of C, whilst A gave a similar but less consistent error.

H. G. R.

**Relation between viscosity of the blood and the relative volume of erythrocytes (haematocrit value).** K. K. NYGAARD, M. WILDER, and J. BERKSON (Amer. J. Physiol., 1935, 114, 128—131).—The relation is linear with a haematocrit val.  $<60\%$ , but above this val.  $\eta$  increases more rapidly.

R. N. C.

**Control of the circulation of the blood.** R. J. S. McDOWALL (Nature, 1936, 138, 488—491).—An extract from an address to the British Association.

L. S. T.

**Blood groups, blood transfer, and blood substitutes.** A. VON DOMARUS (Naturwiss., 1936, 24, 593—600).—A review.

**Accelerating effect of pectin on blood coagulation.** O. RIESSER (Klin. Woch., 1935, 14, 958—961; Chem. Zentr., 1935, ii, 3943).—Intramuscular, intravenous, or oral administration of pectin (I) to dogs shortened the coagulation time without producing secondary effects. The action is related to the acid reaction of (I).

A. G. P.

**Action of formaldehyde on blood coagulation.** A. FISCHER (Enzymologia, 1936, 1, 85—91).— $CH_2O$  inhibits blood clotting by embryo extract. Combination with  $-NH_2$  is suggested.

E. D. Y.

**Role of bivalent metals in the reversible inactivation of jack-bean haemagglutinin.** J. B. SUMNER and S. F. HOWELL (J. Biol. Chem., 1936, 115, 583—588).—Concanavalin-A (I) loses its agglutinating properties (A., 1935, 1143) on contact with dil. mineral acids: this is due to decomp. of Ca, Mn, and Mg compounds and is recovered on neutralisation. Metal-free (I) does not crystallise readily.

H. G. R.

**Specific nature of the inhibition of the coagulating effect exerted by tissue extracts on plasma resulting from incubation of tissue extract with blood-serum.** C. MOORE, V. SUNTZEFF, and L. LOEB (Amer. J. Physiol., 1935, 114, 1—18).

**Blood-clotting: prothrombin fluctuations under experimental conditions.** E. D. WARNER, K. M. BRINKHOUS, and H. P. SMITH (Amer. J. Physiol., 1936, 114, 667—675).—Prothrombin (I) in plasma is determined accurately by conversion into thrombin (II) and measurement of the time of coagulation of fibrinogen (III). The normal (I) content of dog plasma is sufficient to form 200 times the amount of (II) necessary to clot (III) in a few sec., but unless thromboplastin is present in large quantities most of the (I) is not utilised. (I) varies slightly in the plasma from different dogs, but is const. in a single animal,

being unchanged by repeated hæmorrhage or drastic diet changes.  $CHCl_3$  and P poisoning decrease (I) and (III); with  $CHCl_3$  (I) falls before (III) and returns to normal more slowly. (I) remains normal in distemper and turpentine abscess, and in plasma rendered incoagulable by intravenous injection of peptone, or by heparin *in vitro*. Indian ink causes a slight reduction.

R. N. C.

**Properties of thromboplastin (aqueous tissue extracts).** A. J. QUICK (Amer. J. Physiol., 1936, 114, 282—296).—The time of clotting by tissue extracts decreases as the concn. of the extracts increases until a min. val. is reached, beyond which no further decrease takes place. The thromboplastin (I) concn. in extracts of rabbit brain, lung, and thymus is of the same order. The extracts do not clot purified fibrinogen or prothrombin-free plasma. Extraction of brain extract with fat solvents reduces considerably the thromboplastic potency of the solution, but the extract obtained is only slightly active. The activity of the aq. extracts falls with rising temp., brain extract being less stable than lung extract. The activities of extracts from different animals vary with the species.

R. N. C.

**Action of heparin and its relation to thromboplastin.** A. J. QUICK (Amer. J. Physiol., 1936, 115, 317—333).—The clotting time of plasma is inversely  $\propto$  the thrombin (I) concn.; a corrective factor in the equation decreases with increasing concn. of neutral salts. The relationship is destroyed by minute amounts of heparin (II). (II) is not an antithrombin (III), since it inhibits (I) only slightly with purified fibrinogen, but apparently reacts with a plasma constituent to form a (III). Neutral salts are necessary for the reaction. (II) inhibits clotting of prothrombin-free plasma by (I), the inhibitory effect not being influenced by excess of thromboplastin (IV) and Ca in optimal concn. (II) also inhibits the acceleration in clotting of oxalated plasma by excess of (IV) and Ca in optimal concn.; these results indicate that (IV) does not neutralise (II).

R. N. C.

**Inhibiting action of cattle and sheep serum on kidney extracts of cattle and sheep.** E. W. THURSTON, J. E. SMADEL, and L. LOEB (Amer. J. Physiol., 1935, 114, 19—24).—The inhibition curve obtained by addition to the mixture of extract and serum of heparin or a Ca inactivator shows the typical form; it results from inactivation of tissue-coagulin and destruction of thrombin during incubation.

R. N. C.

**Serologic relation of *Brucella* and *Pasteurella*.** L. E. STARR and G. E. SNIDER (J. Infect. Dis., 1934, 55, 384—389).—Cross-agglutination between *Brucella* and *Pasteurella* in cattle sera is demonstrated.

CH. ABS. (p)

**Testing of therapeutic serum. I. Antipneumococcus serum *in vivo* and *in vitro*.** L. COTONI and J. POCHON (Ann. Inst. Pasteur, 1936, 57, 221—239).—A review of methods for testing sera *in vivo* and *in vitro*. A method which uses the neutralisation of the antibody *in vitro* is described, together with the prep. of the antigen, bacterial emulsion, and solution of the polysaccharide. Advantages are sim-

plicity, rapidity, and economy of material. A serum-standard is not needed.

J. N. A.

**Blood-coagulating substance produced by staphylococci, and its relation to disease.** M. PIJOAN (Canad. Med. Assoc. J., 1935, 33, 476—481).—Staphylococci generally may produce a toxin, leucocidin, haemolysin, necrotoxin, staphylokinase (I), and a fibrinolysin. (I) can be washed from the surface of organisms, is destroyed at 85°, and coagulates oxalated plasma. Clot formation does not depend on the Ca-thrombin mechanism.

CH. ABS. (p)

**Antigenic reactions of *Staphylococcus aureus* and its variants.** R. E. HOFFSTADT and G. P. YOUNG (J. Infect. Dis., 1935, 56, 288—296).—Rough and gonidial forms of *S. aureus* afford no protection against smooth and virulent forms. All strains contain heat-stable antigenic fractions in common. Gonidial forms contain a heat-labile fraction in common with rough and smooth forms.

CH. ABS. (p)

**Composition of the active principle of tuberculin. XIX. Differences in antigenic properties of various tuberculin fractions; adsorption on aluminium hydroxide and charcoal.** F. B. SEIBERT (J. Immunol., 1935, 28, 425—432; cf. A., 1933, 1933).—A purified potent tuberculin-protein derivative was unable to stimulate the production of antibodies but reacted specifically with the antibodies when they were formed by means of the whole tuberculin-protein mol. When injected in a particulate form [adsorbed on  $\text{Al}(\text{OH})_3$  or C] it stimulated the production of antibodies and inhibited the precipitin reaction between the whole tuberculin-protein antigen and its antibodies.

CH. ABS. (p)

**Polysaccharide of the typhus bacillus. III. Agglutinin titre in rabbits.** A. SPANEDDA (Boll. Soc. ital. Biol. sperim., 1936, 11, 327—328; cf. this vol., 1010).—Repeated intravenous injection of the polysaccharide produces decreasing febrile reactions, whilst the agglutinin titre increases up to the 4th injection and then slowly falls to a zero val. with subsequent injections; this is probably due to the formation of a sp. antibody.

F. O. H.

**Union with complement as a surface reaction.**—See this vol., 1335.

**Electric impedance and permeability of living cells.** J. F. McCLENDON (Science, 1936, 84, 184—185).

L. S. T.

**Oxygen and carbon dioxide tensions in the subcutaneous tissues of normal subjects.** M. H. SEEVERS (Amer. J. Physiol., 1936, 115, 38—42).—The tensions are of the same order as those previously found for other homothermal animals by the gas depot method. Final equilibrium between the gas pocket and the surrounding tissues is reached only after 5—7 days, when the foreign body reaction has subsided. After this time the partial pressure of  $\text{CO}_2$  remains practically const., whilst that of  $\text{O}_2$  varies considerably.

R. N. C.

**Micro-determination of fluorine [in dental enamel and dentine].**—See this vol., 1351.

**Chloride and total base contents of tendon and cartilage.** M. WHELAN and H. A. SHOEMAKER (Amer. J. Physiol., 1936, 115, 476—479).—Analytical data are given for muscle, skin, tendon, and cartilage from various sources.

R. N. C.

**Distribution of iron in certain tissues of normal and anæmic albino rats.** G. WAKEHAM and H. F. HALENZ (J. Biol. Chem., 1936, 115, 429—434).—The prep. and testing of blood-free tissue are described. The Fe content of the washed tissues of normal rats is in the decreasing order: liver, heart, kidney, striated muscle. In anæmic rats, heart contains > liver, but all three lose Fe.

E. M. W.

**Determination of sulphur in the extract of the silk-rind of cocoons.** G. COLA (Boll. uff. R. Staz. sperim. Seta, 1935, 5, 46; Chem. Zentr., 1935, ii, 4000).—A method of oxidation, followed by pptn. as  $\text{BaSO}_4$ , is described.

H. N. R.

**Composition of the eggs of *Taeniarhynchus saginatus* and *Diphylllobothrium latum*.** I. A. SMORODINCEV and P. I. PAVLOVA (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 29—31).—The eggs of the two species contain, respectively,  $\text{H}_2\text{O}$  72.6, 77.19, org. matter 26.59, 22.30, ash 1.15, 0.66, N 3.57, 3.32, lipins 4.95, 6.88%. In both cases the composition of the eggs differs greatly from that of the worm.

W. McC.

**Phosphagen in echinoid muscle and in electrical tissue.** E. BALDWIN and D. M. NEEDHAM (Nature, 1936, 138, 506).—The partition of P in the electrical tissue of *Torpedo* resembles that in the muscles of the rat and the frog. This tissue, like muscle, contains enzymes capable of catalysing the reactions: phosphoglyceric acid  $\rightarrow$  phosphopyruvic acid (I); (I) + adenylic acid (II)  $\rightarrow$  adenylyl pyrophosphate (III) +  $\text{AcCO}_2\text{H}$ ; (III) + creatine  $\rightarrow$  (II) + phosphagen; and (III)  $\rightarrow$  (II) +  $\text{H}_2\text{PO}_4$ . Certain phosphorylated compounds in presence of enzyme extracts from the jaw muscles of *Sphaerechinus granularis* synthesise two phosphagen-like compounds from creatine and arginine, respectively. Echinoid jaw muscle contains enzymes similar to, if not identical with, those reported above.

L. S. T.

**Liver-glycogen. IV. Molecular structure of glycogen formed after ingestion of galactose by fasted rabbits.** D. J. BELL (Biochem. J., 1936, 30, 1612—1616, and Nature, 1936, 138, 289).—The livers of galactose-fed rabbits and the whole tissue of *Mytilus edulis* yield glycogen,  $[\alpha]_D +201^\circ$  in  $\text{H}_2\text{O}$ , containing 18 glucose units per mol., compared with 12 for normal glycogen, but with no other significant difference.

F. A. A.

**New Zealand fish oils. I. Composition of eel oil (*Anguilla Aucklandii*).** F. B. SHORLAND and I. G. MCINTOSH (Biochem. J., 1936, 30, 1775—1777).—The body- and, more especially, the liver-oil contain vitamin-A. The body-oil (yield 7%; sap. val. 290.4, I val. 122.5) contains 0.8% of unsaponifiable matter. The % of fatty acids resembles those of oils of fresh- $\text{H}_2\text{O}$  fish examined by Lovern (A., 1933, 183). The production of dihydroxystearic acid by oxidation of the  $\text{C}_{18}$  unsaturated acids with

alkaline  $\text{KMnO}_4$  and the results of bromination indicate the presence of oleic and stearidonic acid. No evidence was found of the presence of linoleic or linolenic acid. W. McC.

**Absence of *allocholesterol* from the organism.** E. A. EVANS, jun. (J. Biol. Chem., 1936, 115, 449—451).—No *allocholesterol* (I) is found in the yolk of hens' eggs, using as a test for (I) the ultra-violet absorption spectrum of  $\Delta^{2:4}$ -cholestadiene obtained when (I) is dehydrated in the presence of acid; this test would indicate 0.01% of (I). F. A. A.

**Pigments of the retina. II. Sea robin, sea bass, and scup.** G. WALD (J. Gen. Physiol., 1936, 20, 45—56; cf. this vol., 1012).—The visual purple (I) in all cases is practically identical, spectroscopically, with that from frogs and the combined pigment epithelium and choroid layer contain vitamin-A, flavin, and an unidentified xanthophyll. The visual yellow of the sea robin retina is irreversibly converted into a  $p_H$  indicator at  $p_H > 11$ . This is not removed to form (I) or -A. H. G. R.

**Microchemical detection of pterins in insects.** E. BECKER and C. SCHOPF (Annalen, 1936, 524, 124—144).—The detection of leucopterin is based on the separation of the yellow, cryst. Na salt, the stable Ag salt, and the violet-blue fluorescence of its feebly alkaline solutions. Xanthopterin (I) gives a sharply-defined yellow band which shows an intense yellowish-green fluorescence when adsorbed by  $\text{Al}_2\text{O}_3$  from 0.01%  $\text{HCl-MeOH}$ ; since the breadth of the band  $\propto$  the amount of pigment if the vol. of the solution is restricted an approx. determination may be made. Development by dil. acid decomposes the pigment. The adsorptive power of  $\text{Al}_2\text{O}_3$  from 0.004*N*- $\text{HCl}$  is considerably less. In 20%  $\text{H}_2\text{SO}_4$  (I) yields a solution with weak but distinct red fluorescence. With somewhat greater amounts the separation of the  $\beta$ -Ba salt is possible. There is no certain method for the microchemical differentiation of (I) and chrysopterin (II). The sole difference is that (II) is more readily adsorbed than (I) from dil. aq.  $\text{HCl}$  so that homogeneous (II) gives a distinct band and is thus readily detected. In insects, (II) is usually associated with much (I). Detection of small amounts of erythropterin depends on adsorption from dil. acid solution by  $\text{Al}_2\text{O}_3$ . With natural mixtures, 0.004*N*- $\text{HCl}$  is more suitable than  $\text{MeOH-HCl}$  since it alone affords a clear band of orange colour and dull brown fluorescence. Guanopterin does not give characteristic colour or fluorescence reactions but the characteristic sulphate may be isolated from 0.1—0.2 mg. of material. In the examination of insects for pterins the localisation of pigment at definite positions in the integument, its mode of deposit in the skin tissue, and its microscopic-optical behaviour are as important as the chemical reactions. Preliminary treatment with  $\text{Et}_2\text{O}$  and boiling  $\text{EtOH}$  only is required but insects should be preserved, if necessary, in abs.  $\text{EtOH}$ . The pigments are obtained by two extractions with cold 0.5*N*- $\text{NH}_3$  followed by a single extraction with 2*N*- $\text{NH}_3$ . The united extracts are clarified and evaporated over  $\text{KOH}$  and  $\text{H}_2\text{SO}_4$ . The subsequent treatment depends on the colour of the residue and is illustrated by several examples. H. W.

**New pterins.**—See this vol., 1260.

**Determination of indoxyl in presence of indole in animal tissue.** J. GARCÍA-BLANCO, J. NACLE, and C. HERNÁNDEZ (Anal. Fis. Quím., 1935, 33, 98—104).—Indole (I) is extracted with  $\text{Et}_2\text{O}$  and the indoxyl (II) determined colorimetrically in the acidified solution by means of Obermayer's reagent. (I) increases the amount of (II) lost from the blood and kidney but not the liver of rabbits, during pptn. of the proteins. F. R. G.

**Denaturation and hydration of proteins. II.** NEURATH and H. B. BULL (J. Biol. Chem., 1936, 115, 519—528).— $d$  of natural ovalbumin is  $<$  that of heat- or surface-denatured ovalbumin. The vals. for the max. vol. contraction in  $\text{H}_2\text{O}$  are 53, 24.5, and 30 cu. mm. per g., respectively. The vol. contractions have also been measured in various  $\text{EtOH-H}_2\text{O}$  mixtures. H. G. R.

**Nature of paranuclein.** J. D. HERD (Biochem. J., 1936, 30, 1743—1752).—The rates at which N and P of paranuclein (I) (A., 1926, 970) are rendered sol. in 10%  $\text{CCl}_3\text{-CO}_2\text{H}$  by hydrolysis with pepsin, trypsin, papain, and 10%  $\text{NaOH}$  indicate a P-free, alkali-resistant nucleus containing 20% of the initial N of (I). Data from hydrolyses, physical properties,  $\text{NH}_2$ -acid distribution, and combination with I show (I) to consist of two fractions. F. O. H.

**Liver-proteins. I. Storage of protein.** J. M. LUCK (J. Biol. Chem., 1936, 115, 491—510).—Protein from the blood-free livers of rats may be extracted at 0—3° as four fractions, corresponding with globulin-II, euglobulin, pseudoglobulin, and albumin. In rats kept on a low-protein diet, the amounts in these fractions are 5.07, 4.58, 1.06, and 0.86 g. per 100 g. of liver, respectively. On a high-protein diet these vals. are all 50—60% higher, indicating that no single protein can be regarded as especially involved in protein storage in the liver. On the high-protein diet, the liver increases in wt. as well as in % protein. Under the conditions observed, other organs do not participate in protein storage. F. A. A.

**Polysaccharoproteins. X. Rôle of individual amino-acid residues.** S. J. VON PRZYBYCKI, K. KASPRZYK, and H. RAFAŁOWSKA (Biochem. Z., 1936, 286, 360—372).—Ovalbumin, lactalbumin, pseudoglobulin, globin, and histone of erythrocytes (goose) have no affinity for P-free polysaccharides (I). Euglobulin, ovoglobulin, fibroin, gelatin, edestin, clupcin, and myosin form symplexes (II) with (I), whilst serum-albumin and caseinogen unite only to a slight extent. The formation of (II) is not dependent on the protein particle size or physical structure nor on the presence of impurities, but (II) are formed only by those proteins which contain considerable amounts of tyrosine or arginine. P. W. C.

**Cross-linking formation in keratins.**—See this vol., 1396.

**Enzymic histochemistry. XVIII. Localisation of peptidase in marine ova.** H. HOLTER (J. Cell. Comp. Physiol., 1936, 8, 179—200).—Peptidase activity, in the three species examined, is localised in

the hyaline ground substance (matrix) of the cytoplasm, and is not bound to granular matter.

E. A. H. R.

Colloid osmotic pressure of the body-fluids of fresh-water animals. P. MEYER (Nature, 1936, 138, 287—288).—The vals. are in order of phylogenetic development, but are 20—35% < those of the corresponding marine animals.

L. S. T.

Abnormal fluorescence of human milk. C. GRIEBEL (Z. Unters. Lebensm., 1936, 72, 46—50).—Abnormalities are recorded due to (a) ingestion of 1:8-dihydroxyanthraquinone, (b) a vegetarian diet, and (c) the presence of unidentified cells in the milk.

E. C. S.

Composition of the envelopes of milk-fat globules. G. SCHWARZ and O. FISCHER (Milch. Forsch., 1936, 18, 53—67).—The material surrounding milk-fat globules was isolated by repeatedly washing cream with aq. NaCl, churning, separating butter fat, and pptn. with COME<sub>3</sub>. The material contained ash 6.95, N 11.25, S 1.12, and P 0.61% in the dry matter. Its protein nature was established and its N distribution determined.

W. L. D.

Rennet test [for milk]. M. F. DUNGERN and G. NELZ (Milch. Forsch., 1936, 18, 46—52).—A semi-micro-method described involves an apparatus similar to that used in the Bürker test for the time of blood clotting. The method is trustworthy under various conditions of temp. and milk acidity.

W. L. D.

Determination of calcium diffusing from milk during compensated dialysis. G. SARZANA (Boll. Soc. ital. Biol. sperim., 1936, 11, 266—267).—Dialysis against isotonic aq. KCl of varying [Ca<sup>++</sup>] gives a diffusible Ca fraction of 18—19 and 37—50% for cow's and human milk, respectively, whilst ultrafiltration gives 30—37 and 44—67%, respectively.

F. O. H.

Factors influencing the lactose content of milk. W. E. PETERSEN (Proc. Amer. Soc. Animal Prod., 1936, 58—63).—Increasing the blood-glucose (I) beyond normal levels did not materially increase the lactose (II) content of milk. Lowering (I) or leaving the milk in the udder caused a decline in (II).

NUTR. ABS. (m)

Use of ammonium sulphate serum of milk in serological investigations. M. F. BENGEL and E. BOHM (Z. Unters. Lebensm., 1936, 72, 92). H. KLUGE (*ibid.*, 92).—Polemical (cf. *ibid.*, 71, 405).

E. C. S.

Forces concerned in the absorption of the cerebrospinal fluid. L. H. WEED (Amer. J. Physiol., 1935, 114, 40—45).—The total effective force is compounded of the colloid-osmotic pressure of the blood and a hydrostatic factor.

R. N. C.

Reducing substance in human cerebrospinal fluid. M. MITOLO (Boll. Soc. ital. Biol. sperim., 1936, 11, 332—334).—0.5 c.c. of the fluid from 22 diseased persons reduces 0.75—4.57 (average 2.12) c.c. of 0.01% 2:6-dichlorophenol-indophenol.

F. O. H.

Determination of ethyl alcohol in saliva. J. C. ABELS (Proc. Soc. Exp. Biol. Med., 1936, 34, 504—505).—EtOH is absent from normal saliva, but in intoxication the EtOH content is closely correlated

with that of the blood and also with the degree of intoxication.

W. O. K.

Effects on gastric secretion in dogs of various food substances employed in the treatment of gastric ulcer. A. ALLEY (Amer. J. Digest. Dis. Nutrition, 1934, 1, 555—560).—Milk or cream produced continuous secretion, that with cream being more prolonged and that with milk of higher peptic power. Alkalis increase the vol. and acidity of the secretion. Egg-white, butter, and cream of wheat induced small secretion, that with the last named being of high peptic power and low acidity.

CH. ABS. (p)

Effect on gastric juice secretion of various cooked preparations of haddock and of lobster. A. ALLEY (Amer. J. Digest. Dis. Nutrition, 1934, 1, 182—184).—Lobster caused secretion of shorter duration but of much greater vol., acid and mucin contents than did boiled haddock.

CH. ABS. (p)

Gastric secretagogic value of various digestive secretions. M. S. KIM and A. C. IVY (Amer. J. Physiol., 1936, 115, 386—388).

R. N. C.

Inhibitory effect of the acidity of the gastric contents on the secretion of acid by the stomach. C. M. WILHELMJ, F. T. O'BRIEN, and F. C. HILL (Amer. J. Physiol., 1936, 115, 429—440).—HCl secretion in the dog is progressively inhibited by increasing [HCl] > 0.005N in a Liebig's extract test meal, inhibition being nearly complete at 0.10N. The inhibition is of gastric origin, and is probably not due to hormonal action. The composition of acidic and non-acidic fluids entering the stomach is unaffected by the inhibition.

R. N. C.

Improved gastric test meal and a study of the secretory curve in whole stomach pouches and in the normal intact stomach. C. M. WILHELMJ, F. T. O'BRIEN, and F. C. HILL (Amer. J. Physiol., 1936, 115, 5—22).—The meal contains 15 mg. of phenol-red per litre. Regurgitation of duodenal secretions keeps the [HCl] of the total fluid entering the secreting stomach < the average val. found in isolated pouches. The regurgitated duodenal contents, with a powerful and maintained stimulus e.g., Liebig's extract of meat, are insufficient to lower gastric [H<sup>+</sup>], but prevent or slacken further rise.

R. N. C.

Some properties of Castle's intrinsic factor. C. FLOOD and R. WEST (Proc. Soc. Exp. Biol. Med., 1936, 34, 542—543).—Exposure of normal gastric juice to  $p_{H}$  10.0 for 30 min. destroys peptic activity without materially affecting the intrinsic anti-anæmic factor (cf. A., 1932, 1156). Normal gastric juice produced no reticulocyte response, but, when added to boiled liver, increased the effect of the latter. Purified pepsinogen administered parenterally was inert.

W. O. K.

Volumetric micro-determination of spermine in semen. A. BOLLIGER (Med. J. Australia, 1935, 784—792).—The semen is acidified with CCl<sub>3</sub>-CO<sub>2</sub>H, the filtrate neutralised with CaCO<sub>3</sub>, and the spermine (I) pptd. as picrate, the picric acid content of which is determined by titration with methylene-blue (A.,

1934, 1322). The (I) content varied from 69 to 117 mg. per 100 c.c. of semen. J. N. A.

**Urinary balance and diuresis.** S. BELLUC, J. CHAUSSIN, J. COTTET, H. LAUGIER, and T. RANSON (Compt. rend., 1936, 203, 273—275).—Diuresis bears an inverse relationship to salt concn. P. G. M.

**Phenolsulphonaphthalein renal function test in dogs.** D. A. COLLINS (Amer. J. Physiol., 1936, 115, 27—30). R. N. C.

**Nitrogen partition in urine of various primates.** M. B. RHEINBERGER (J. Biol. Chem., 1936, 115, 343—360).—Subhuman primates are similar to children in retaining varying amounts of N. Urea,  $\text{NH}_3$ , creatinine, and undetermined N are distributed as with children or subjects on a vegetarian diet. Excreted uric acid increases from Old World monkeys to apes in the direction of greater similarity to man. E. M. W.

**Neutral sulphur of normal and pathological urines.** A. FRIEDRICH and E. BAUER (Z. physiol. Chem., 1936, 242, 261—270).—In healthy human urine the neutral S constitutes 7—13% of the total S. Consumption of protein-rich food increases urinary, neutral, and total S but does not alter the ratio neutral S : total S. The ratio is increased in fevers, in tuberculosis, and sometimes in carcinoma and liver diseases. In a rabbit the ratio was doubled by P poisoning. Increase in urinary neutral S results from diet too rich in protein and from diseases which result in lack of  $\text{O}_2$  and decomp. of protoplasm in the organism; except in cystinuria the increase is a measure of the gravity of the disease. W. McC.

**Sulphur partition in cat urines following injections of monobromobenzene, cystine, and methionine.** R. W. VIRTUE (Proc. Soc. Exp. Biol. Med., 1936, 34, 425—427).—Administration of PhBr to cats results in the excretion in urine of *p*-bromophenylmercapturic acid. The high urinary N found in fasting animals after PhBr administration suggests that the tissues are broken down in order to supply the cysteine required. After injection of cystine and methionine the extra S is excreted in the urine largely as sulphate. W. O. K.

**Determination of iron in phosphate-rich material (faeces).** RANGIER and LAFRANÇOISE (J. Pharm. Chim., 1936, [viii], 24, 266—268).—The material (e.g., dog's faeces) is boiled with aq. HCl (1 : 1) followed by dil.  $\text{HNO}_3$ , filtered, and the filtrate treated with excess of aq.  $\text{NH}_3$ , the resulting ppt.  $[\text{Ca}_3(\text{PO}_4)_2 + \text{Fe}(\text{OH})_3]$  being washed with  $\text{H}_2\text{O}$  and dissolved in boiling dil.  $\text{H}_3\text{PO}_4$ , and the  $\text{Fe}^{+++}$  reduced (Zn) and then oxidised with 0.1N-KMnO<sub>4</sub>. F. O. H.

**Pyruvic acid in urine after hard exercise.** R. E. JOHNSON and H. T. EDWARDS (Science, 1936, 84, 140—141).— $\text{AcCO}_2\text{H}$ , but not  $\text{AcCHO}$ , appears to be one of the variable constituents of blood and urine during hard exercise. L. S. T.

**Excretion of inulin and creatinine at low urine flows by the normal dog.** J. A. SHANNON (Amer. J. Physiol., 1936, 114, 362—365).—The mean ratio of simultaneous inulin and creatinine clearance is 0.993 with a standard deviation of 0.048 and max.

variations of +0.097 and -0.083. Neither substance is passively reabsorbed during excretion by the normal kidney. R. N. C.

**$\beta$ -Lactose : effect on the flora of the infant's stool.** J. R. GERSTLEY, E. PENRUDDOCKE, and G. LAWRENCE (Arch. Pediatrics, 1935, 52, 552—561).— $\beta$ -Lactose has the same advantages as  $\alpha$ -lactose in the infant's diet, and has a favourable influence on the  $p_H$  and flora of stools. CH. ABS. (p)

**Common salt and other agents. Uses in certain [pathological] conditions.** W. W. LANG (Vet. Rec., 1936, 48, 879—886).—A lecture and discussion. Uses of injections of NaCl-Na citrate are considered. A. G. P.

**Iron absorption and treatment of anæmia. I, II.** G. WALLBACH (Folia hæmatol., 1936, 54, 201—210, 211—216).—I. In mice given 0.01 g. of Fe daily for 8 days, storage of Fe after the same dose in different chemical combinations was very different and did not depend on the solubility in  $\text{H}_2\text{O}$  or the valency of the Fe.

II. After parenteral administration of 0.1 mg. of different forms of Fe certain forms, especially  $\text{Fe}^{II}$  salts, were deposited in the liver and others, such as reduced Fe, in the epithelial cells of the small intestine, whereas salts such as the citrate remained at the site of injection. NUTR. ABS. (m)

**Significance of loss of serum-protein in therapy of severe burns.** D. O. WEINER, A. P. ROWLETTE, and R. ELMAN (Proc. Soc. Exp. Biol. Med., 1936, 34, 484—486).—After severe burns  $\text{H}_2\text{O}$  and protein are lost from the blood, which consequently has often an abnormally high erythrocyte count but a low serum-protein content. Administration of solutions containing only glucose and electrolytes is therefore not so effective as is blood-plasma. W. O. K.

**Induced chiasma formation in somatic cells by a carcinogenic hydrocarbon [methylcholanthrene].** E. M. HEARNE (Nature, 1936, 138, 291). L. S. T.

**Influence of diets containing proteins of various fishes on the growth of tumour in rats. I.** S. TOKUYAMA and W. NAKAHARA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 29, 253—271).—Sarcoma implanted on rats fed on a diet containing 15% of EtOH-extracted protein grew less rapidly when the protein was derived from various fish than from horse meat. The tumour growth rates were correlated with the growth of the animals before tumour implantation. W. O. K.

**Transmissible agent in the Rous chicken sarcoma no. 1.** J. W. JOBLING and E. E. SPROUL (Science, 1936, 84, 229—230).—The lipin extract of this sarcoma, obtained by the use of a sp. solvent at low temp. under relative anaerobiosis, transmits the tumour when allowed brief contact with chicken tissue extract and promptly inoculated. Tumours do not develop when the lipin extract is inoculated alone or into previously injured breast muscle. L. S. T.

**Contents of trypsin, cathepsin, amylase, and lipase in cancerous growths and blood.** G. VERCELLANA (Boll. Soc. ital. Biol. sperim., 1936,

11, 328—329).—The enzymes were not found in cancerous growths (excepting amylase, a normal constituent, in a parotid growth) or blood.

F. O. H.

**High-sugar diets and dental caries in the white rat.** C. D. M. DAY, R. G. DAGGS, and H. J. SEDWICK (J. Amer. Dental Assoc., 1935, 22, 913—925).—Prolonged feeding of diets containing 20—55% of sugar was not conducive to the incidence of caries when sufficient minerals and vitamins were supplied.

CH. ABS. (p)

**Diet and dental caries.** R. W. BUNTING (J. Amer. Dental Assoc., 1935, 22, 114—122; cf. A., 1934, 99).—High-sugar diets favoured the development of caries in children by influencing the environment of the teeth rather than their resistance. No const. relation was found between caries activity and the Ca, P, or vitamin-C or -D contents of the diet or the chemical composition of blood or saliva.

CH. ABS. (p)

**Carbohydrate degradation in relation to dental caries.** L. S. FOSDICK and H. L. HANSEN (J. Amer. Dental Assoc., 1936, 23, 401—407).—In the degradation of carbohydrate to lactic acid, with subsequent dissolution of tooth enamel, the enzymes of yeast and tissue play an important part. *In vitro*, human enamel, suspended in a solution of glucose and saliva, was dissolved by the acids produced. NaF prevented dissolution. A correlation of this fact with the low susceptibility of mottled teeth to decay is suggested. A combination of yeast and of (otherwise inactive) *B. acidophilus* was more potent than yeast alone.

NUTR. ABS. (m)

**Acid-base balance of diets which produce immunity to dental caries among South Sea Islanders and other primitive races.** W. A. PRICE (Dental Cosmos, 1935, 77, 841—846).—The primitive diet was potentially acid-forming. In changing to civilised diets (deficient in certain minerals and vitamins) the potential acidity did not increase with the enhanced susceptibility to caries.

CH. ABS. (p)

**Impaired glucose tolerance in certain alimentary disorders of childhood: treatment with liver extract.** C. W. ROSS (Lancet, 1936, 231, 556—559).—In coeliac disease, chronic intestinal indigestion, and abdominal glandular tuberculosis a flat oral glucose tolerance curve is associated with a high intravenous curve, indicating deficient carbohydrate absorption power from the intestine. Administration of liver extract improves the impaired glucose tolerance.

L. S. T.

**Intestinal absorption in coeliac disease; effect of liver extracts on carbohydrate metabolism.** C. W. ROSS (Trans. Roy. Soc. Trop. Med. Hyg., 1936, 30, 33—60).—Evidence for defective absorption of glucose and a resulting decrease in glucose tolerance, as well as for decreased sensitivity to insulin, is reported. Tests indicated that the factor (probably insulin-kinase), present in total liver extracts, which improves glucose tolerance is not identical with Castle's essential liver factor.

NUTR. ABS.

**Chemical aspects of dermatitis.** H. E. COX (Chem. and Ind., 1936, 775—781).—An address.

**Treatment of severe diabetes in children with protamine insulinate.** T. I. BENNETT and A. M. GILL (Lancet, 1936, 231, 416—417).

L. S. T.

**Specific dynamic action of protein in pancreatic diabetes.** G. C. RING (Amer. J. Physiol., 1936, 115, 419—423).—The calorogenic action of protein (I) in underfed diabetic cats is > normal. Increased metabolism does not affect the action of (I), although those of fat and carbohydrate are reduced. The R.Q. after ingestion of (I) is < that in normal animals. The increased metabolism of diabetes is not due to sp. dynamic action of (I).

R. N. C.

**Evidence of altered carbohydrate metabolism in cats with hypothalamic lesions.** W. R. INGRAM and R. W. BARRIS (Amer. J. Physiol., 1936, 114, 562—571).—Bilateral lesion in the anterior supra-chiasmatic portion of the hypothalamus, or hypophysectomy, increases the sensitivity of the cat to insulin. The response of blood-sugar to adrenaline is also diminished by severe lesions in the supra-chiasmatic region. Lesions in this region abolish the normal response to the hyperglycaemic effect of anterior pituitary suspension (I); hypophysectomy retards the action of (I). Liver-glycogen remains normal.

R. N. C.

**Effect of experimental hypothalamic lesions on blood-sugar.** R. W. BARRIS and W. R. INGRAM (Amer. J. Physiol., 1936, 114, 555—561).—Lesions at almost any point in the hypothalamus of the cat cause a transient hyperglycaemia. Mild chronic hypoglycaemia generally follows when the lesion is in the anterior portion, particularly if the nucleus filiformis is destroyed or atrophic.

R. N. C.

**Blood-lipins in lipaemia retinalis.** A. MARBLE and R. M. SMITH (Arch. Ophthalmol., 1936, 15, 86—94).—In lipaemia retinalis occurring in two boys with severe diabetes which had been poorly controlled, the total lipins of the blood amounted to 14.1 and 7.5%, respectively. The greatest increase took place in the fatty acid fraction, with relatively large increases also in the cholesterol and phospholipin fractions.

NUTR. ABS. (m)

**Chemistry of muscle in progressive muscular dystrophy. Analysis of biopsy samples from the deltoid.** J. A. COLLAZO, J. BARBUDO, and I. TORRES (Deut. med. Woch., 1936, 62, 51—54).—In dystrophic muscle there exists, together with fatty degeneration of the connective tissue, an insufficiency of phosphagen (I) and glycogen (II), (I) being practically absent in severe cases. There is also a marked lack of (II) and lactic acid, and a reduced H<sub>2</sub>O content. The inorg. P of muscle is not increased. In a severe case of myasthenia the vals. for muscle-(II) and -(I) were subnormal but not to the extent found in the dystrophies.

NUTR. ABS. (m)

**Metabolic studies in osteoporosis.** M. ADAMS, W. M. BOOTHBY, and A. M. SNELL (Amer. J. Physiol., 1936, 114, 383—398).—Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> fed in large amounts to a patient with senescent osteoporosis produces storage of Ca and P; the extent of the storage is limited by a factor, exhaustion of which results in a decreasing retentive power. Viosterol (I) added to Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>

renders Ca retention more marked. Ca retention during administration of Ca lactate (II) is  $>$  during administration of an equiv. amount of  $\text{Ca}_3(\text{PO}_4)_2$ ; (I) apparently produces little change in Ca balance when (II) alone is given. N is retained throughout; K, Na, and Mg balances are unchanged. R. N. C.

**Hydræmia as a factor in the anæmia of pregnancy.** H. FELDMAN, E. C. VAN DONK, H. STEENBOCK, and E. F. SCHNEIDER (Amer. J. Physiol., 1936, 115, 69—77).—The  $\text{H}_2\text{O}$  content rises in the blood of pregnant women whilst cell vol., hæmoglobin level, and  $n$  fall. These changes do not occur in the cow. R. N. C.

**Relation of pregnancy and lactation to extirpation diabetes in the dog.** F. P. CUTHBERT, A. C. IVY, B. L. ISAACS, and J. GRAY (Amer. J. Physiol., 1936, 115, 480—496).—Glycosuria in depancreatized bitches, maintained with a uniform diet and a dose of insulin (I) permitting slight glycosuria, is increased in early pregnancy, decreased in late pregnancy, and further decreased in lactation. The reduction is due to passage of glucose and glucose-forming substances into the foetus. Pancreatectomy near term does not cause hyperglycæmia in presence *in utero* of  $\approx 3$  viable foetuses. (I) does not suppress the anti-hyperglycæmic effect exerted by the metabolites of near-term pregnancy. The metabolisms of dogs depancreatized before pregnancy and near term show considerable differences, the latter condition being the more analogous to that of the human patient. R. N. C.

**Blood-lipins during pregnancy in guinea-pigs.** E. M. BOYD and M. D. FELLOWS (Amer. J. Physiol., 1936, 114, 635—641).—Lipæmia becomes marked in the second half of gestation, the increase occurring in the plasma. Total lipins, phospholipins, and free cholesterol (I) are increased to 4 times and neutral fat to 5 times the normal vals., whilst esterified (I) falls 50%, this decrease being continuous and progressive from early pregnancy. R. N. C.

**Nutritive value of canavanine (amino-acid).** VI. **Influence of canavanine on pregnancy and parturition.** M. OGAWA (J. Agric. Chem. Soc. Japan, 1936, 12, 828—832).—Canavanine is not essential for pregnancy, but it is important for the health of pregnant animals. (Cf. A., 1935, 1417.) J. N. A.

**Role of acidosis and phosphate retention in the pathogenesis of rickets and rachitic tetany of infants.** N. MORRIS, F. J. FORD, and S. GRAHAM (Acta paediat., 1935, 18, 50—91).—The active stage of rickets in two children, one with and one without tetany, was accompanied by increased  $\text{NH}_3$  and decreased titratable acid in the urine. Administration of adexolin was followed by an increased retention of Ca and P, a decrease in urinary  $\text{NH}_3$ , and an increase in the titratable acid. Before the onset of rickets a child with coeliac disease had an approx. normal output of urinary  $\text{NH}_3$  and titratable acid, although mineral retention was poor. The examination of Ca and P balances of children with rickets, with and without tetany, and the administration of P to a patient depleted of Ca through coeliac disease,

failed to show any relation between tetany and high P retention. NUTR. ABS. (*m*)

**Blood buffer values in mineral deficiency.** I. N. KUGELMASS (Amer. J. Digest. Dis. Nutrition, 1936, 2, 730—732).—The serum of rachitic infants had a much lower buffering power to added acid and alkali than had that of normal infants. NUTR. ABS. (*m*)

**Bone-ash in prevention and healing of experimental rat rickets.** T. F. ZUCKER (Science, 1936, 84, 162—163).—In curative experiments, supposedly substantial healing effects raise the bone-ash through only approx. one fifth of the interval between the rachitic and the full vitamin-D prevention levels. L. S. T.

**Tropical sprue with special reference to intestinal absorption.** I. N. H. FAIRLEY (Trans. Roy. Soc. Trop. Med. Hyg., 1936, 30, 9—32).—Decreased absorption of fat (with hypocalcæmia) and of glucose are noted, but starch digestion and protein metabolism are not affected. NUTR. ABS.

**Relation of serum-phosphates to parathyroid tetany.** J. H. JONES (J. Biol. Chem., 1936, 115, 371—379).—Rats fed on a low-Ca diet with 4% of basic Al acetate show no tetany after parathyroidectomy and the serum-Ca remains high and the -P low. Fasting after parathyroidectomy causes tetany; the serum-P rises and the -Ca falls. With low available P serum-Ca is high enough to prevent tetany on diets deficient in Ca. The P excretion theory of parathyroid function is discussed. E. M. W.

**Influence of dietary deficiencies on the transmission of trachoma to monkeys.** R. A. HETLER and W. M. JAMES (Amer. J. Ophthalmol., 1934, 17, 1048—1054).—Follicular changes developed in the inoculated eyes of well- and ill-nourished monkeys but not in rats, rabbits, or guinea pigs receiving diets low in vitamins and protein but high in fats. CH. ABS. (*p*)

**Effect of diet and vitamins on trachoma.** C. E. RICE, R. SORY, J. E. SMITH, P. E. FAED, and A. A. DRAKE (Amer. J. Ophthalmol., 1934, 17, 735—741).—No effects in the course of trachoma were observed. CH. ABS. (*p*)

**Metabolism of cartilage.** E. G. L. BYWATERS (Nature, 1936, 138, 288).—A reply to criticism (cf. this vol., 1143). L. S. T.

**Respiratory metabolism of stimulated frog's muscle.** C. L. GEMMILL (Amer. J. Physiol., 1936, 115, 371—375).—The R.Q. averages 0.90,  $\text{O}_2$  consumption 357 cu. mm. per g. of muscle per hr., and the tension developed 195 kg. per g. per hr.  $\text{O}_2$  consumption and the tension developed under aerobic conditions show a linear relationship. R. N. C.

**Age and tissue respiration.** J. M. PEARCE (Amer. J. Physiol., 1936, 114, 255—260).—The  $\text{O}_2$  consumption of excised mouse tissue decreases as age increases. The greatest fall occurs in the liver, and the least in the kidneys. R. N. C.

**Oxidation-reduction in the small intestine and liver of rats during intestinal absorption.** G. PERETTI (Boll. Soc. ital. Biol. sperim., 1936, 11, 336—

337).—Following ingestion of olive oil or glucose, the reducing power (to 2:6-dichlorophenol-indophenol) of the liver and, to a smaller extent, of the small intestine and lung tissue increases.

F. O. H.

Oxygen consumption and carbon dioxide production of frog's retina in darkness and light. J. JONGBLOED and A. K. NOYONS (Z. Biol., 1936, 97, 399—408).—The retina, maintained in darkness for 15–60 min. in contact with the pigmented epithelial layer, has an  $O_2$  consumption and a  $CO_2$  production approx. 22–26% > those of the retina exposed to light.

F. O. H.

Effect of bile salts on the oxygen consumption of dog tissues. W. H. STRAIN and M. E. MARSH (Amer. J. Physiol., 1936, 115, 82–89).—With increasing concn. of Na bile salts in Ringer- $PO_4$ -glucose medium, a "crit. inhibitory concn." is reached above which respiration is more or less inhibited. The inhibiting effect of conjugated bile salts is < that of unconjugated salts, whilst that of Na glycocholate (which is foreign to the dog) is > that of taurocholate, suggesting specificity in conjugation.

R. N. C.

Regularity of nutritional response to chemical intake. H. C. SHERMAN and H. L. CAMPBELL (Proc. Nat. Acad. Sci., 1936, 22, 478–481; cf. A., 1935, 1154).—Rats from families surviving for 8 generations on a diet poor in "protective foods" responded normally, in respect of growth and development, to supplementary feeding with Ca, vitamin-A and  $-B_2$ , and (to a smaller extent) with protein.

A. G. P.

Diet in relation to reproduction and rearing of young. J. F. FEASTER and V. E. NELSON (Amer. J. Physiol., 1936, 115, 147–154).

R. N. C.

Influence of calcium carbonate in the feed of laying hens on digestion. G. D. BUCKNER and A. H. HARMS (Poultry Sci., 1935, 14, 360, 375, 380).—Analysis of the droppings indicates that large amounts of  $CaCO_3$  in the ration lower the digestion of N-free extractives and increase that of protein.

A. G. P.

Availability of calcium salts for bone formation and rickets prevention in chicks. H. J. DEOBALD, C. A. ELVEHJEM, E. B. HART, and J. G. HALPIN (Poultry Sci., 1936, 15, 42–47).—In chicks receiving a basal rachitogenic ration supplemented with various Ca salts and cod-liver oil, the ash content of fat-free bone was higher when the supplement contained P as well as Ca. The Ca in compounds examined (limestone, gypsum, Ca gluconate, bone meal, rock phosphate) was uniformly available for bone formation. If the cod-liver oil given was in crit. amounts, sol. Ca salts (lactate) were more effective than the insol. salts (pptd. silicate). With very insol. silicates the availability  $\propto$  solubility in dil. acid and was not influenced by the amount of oil supplied.

A. G. P.

Calcium carbonate versus calcium sulphate in swine rations. C. W. MCCAMPBELL and C. E. AUBEL (Amer. Soc. Animal Prod. Rec. Proc. 27th Ann. Meet., 1934, 189–190).—When fed as supplements to a linseed meal-wheat-maize ration, finely

ground limestone and gypsum were similarly effective in respect of influencing the serum-inorg. Ca, inorg. P of whole blood, breaking strength of bones, and daily gain in wt.

CH. ABS. (p)

Refecation in the rat. Preparation of basic materials for deficiency diets. S. BLISS (J. Nutrition, 1936, 11, 1–19).—Refecation is readily produced in rats by feeding diets with potato starch as carbohydrate. Growth of such rats is not attributable to unsuspected vitamin-B contamination of the diet. Raw starch from refected faeces and pure raw potato starch behave similarly towards pancreatic digestion mixtures *in vitro*.

A. G. P.

Purified diet satisfactory for growth, reproduction, and lactation in rats. W. M. COX and M. IMBODEN (Proc. Soc. Exp. Biol. Med., 1936, 34, 443–446).—The diet consisted of casein, 20; dextrin, 55.1; lard, 9.0; protein-free dried extract of brewer's yeast (equiv. in  $-B_1$  to 24% and in  $-B_2$  to 8% of yeast), 4; wheat-germ oil, 1.6; carotene (0.3% in maize oil), 0.3;  $Ca(OAc)_2$  1; salts, 3.1; and rice cellulose 5.9 parts.

W. O. K.

Vitamin-D content and haemoglobin-building properties of dehydrated kelp for chicks. M. W. MILLER and G. E. BEARSE (Poultry Sci., 1936, 15, 19–22).—The kelp had little -D activity and did not affect the haemoglobin content of chick blood.

A. G. P.

Haemoglobin content of the blood of laying hens on practical poultry rations. M. O. SCHULTZE, C. A. ELVEHJEM, E. B. HART, and J. C. HALPIN (Poultry Sci., 1936, 15, 9–13).—A ration supplying 14 mg. of Fe and 0.5 mg. of Cu per head per day supports heavy egg production without concurrent lowering of the haemoglobin content of the blood.

A. G. P.

Site of renal elimination of haemoglobin in the rabbit. I. GERSH (Anat. Rec., 1936, 65, 371–375).

R. N. C.

Effect of previous feeding on the nitrogen excretion of fasting birds. J. C. FRITZ, W. A. HENDRICKS, and H. W. TITUS (Amer. J. Physiol., 1936, 115, 281–286).—N excretion by cocks falls when fasting begins, but on the 2nd and 3rd days rises or falls according as the previous diet was abnormally low or high in protein. After the 3rd day N excretion remains practically const. The source of the protein in the diet does not affect the result. Recovery after fasting is most rapid in birds previously fed with a normal diet.

R. N. C.

Effect of (A) high-fat and (B) high-protein diet on the growth of rats. C. Y. CHEN (Nutrit. Bull. B, April, 1936, No. 3, 23–27, 29–36).—The ill effects of both diets were counteracted by adding a 50% EtOH extract of yeast, but not by a 70% extract.

NUTR. ABS.

Effect of a low-protein ration on the pre-natal and post-natal development of the rat. C. P. THOMPSON (Amer. Soc. Animal Prod. Rec. Proc. 27th Ann. Meet., 1934, 177–178).—Low-protein rations did not affect the no. of young per litter but lowered their average wt. and increased the proportion of stillborn. At higher protein levels (17.1%) rats

stored 19% more of the total N ingested than did those receiving 10.2% of protein. CH. ABS. (p)

**Rate of growth in relation to plane of protein intake.** A. G. HOGAN, S. R. JOHNSON, and U. S. ASHWORTH (Amer. Soc. Animal Prod. Rec. Proc. 27th Ann. Meet., 1934, 179—181).—Animals on a high-protein (20%) diet made larger gains in wt., and stored more  $H_2O$  and protein but less fat, than did those on a low-protein (10%) diet. CH. ABS. (p)

**Digestibility of dietary protein in the ruminant. I. Endogenous nitrogen excretion on a low-nitrogen diet and in starvation. II. Digestibility of protein following a prolonged fast. Nitrogen metabolism.** J. C. D. HUTCHINSON and S. MORRIS (Biochem. J., 1936, 30, 1682—1694, 1695—1704).—I. The faecal N excretion of goats and sheep on a N-free diet increases with the quantity of food taken and the presence of fibre in the diet. With the cow, goat, and sheep starvation following a low-N diet causes an increased urinary N excretion, the most notable changes being those of urea (I) and creatine (II); increasing the energy intake on a N-free diet causes a progressive decrease in the urinary excretion of (I) and (II).

II. The greater is the biological val. of the protein and the greater the requirement of the animal for protein, the less is the digestibility; the faecal N excreted under conditions of poor utilisation is volatile at  $180^\circ$ . From studies of the partition of the urinary N of cows after ingestion of food after a period of starvation it is concluded that increased deamination leads to increased (I),  $NH_3$ , and  $NH_2$ -acid excretion; when the ingested protein is used for tissue anabolism an increase of (II) output occurs. The mean ratio of retained N to S over a long period is similar to that for body tissue. H. D.

**Uric acid synthesis in birds. IV. Uric acid synthesis in pigeons; a purine synthesis. (i) Nucleic acid metabolism in the pigeon. (ii) The "precursor" as a carbon source in uric acid synthesis. (iii) Nitrogen source in uric acid synthesis.** W. SCHULER and W. REINDEL (Klin. Woch., 1935, 14, 1238—1242; Chem. Zentr., 1935, ii, 3792—3793).—(i) [with A. LEHMER]. Liver is unable to effect fission of nucleic acid or nucleoside, or to oxidise purines to urea.

(ii) [with H. FRIEDRICH]. None of many substances examined can be the precursor of uric acid. Kidneys are unable to regenerate the precursor although they always contain considerable amounts. The production of precursor from liver powder is confirmed.

(iii) [with O. HENZ]. See A., 1935, 1153.

A. G. P.

**Choline ester formation in, and choline esterase activities of, tissues *in vitro*.** J. H. QUASTEL, M. TENNENBAUM, and A. H. M. WHEATLEY (Biochem. J., 1936, 30, 1668—1681).—A substance considered to be a choline ester (I), which causes eserinated leech muscle to contract, is formed during aerobic incubation of brain cortex slices in the presence of eserine. The rate ( $R$ ) of (I) formation is decreased by  $CN'$  and increased 4—5 times by glucose (II) with or without added Ca and K with  $HPO_4''$  medium; addition of Ca and K to a (II)- $HPO_4''$  medium increases  $R$ .

In  $HCO_3'$  medium (II) increases  $R$  in the absence of added  $Ca''$  and  $K'$ . Addition of  $Ca''$  and  $K'$  lowers  $R$  so that adding (II) to a Ringer- $HCO_3'$  medium has little or no effect. The possibility that these effects are due to influences on (II) metabolism is suggested. Na lactate, pyruvate,  $\alpha$ -glycerophosphate, and glutamate increase  $R < (II)$  with or without added  $Ca''$  and  $K'$ ; Na succinate is without influence, also NaF in the presence of (II) although in this case  $Q_{10}$  is considerably reduced. Addition of choline or NaOAc is without influence on  $R$  so that it is assumed that the synthesis of acetylcholine (III) is not from the products of its hydrolysis. Kidney, liver, spleen, and testis do not produce (I) under the conditions in which brain does. The hydrolysis of (III) by tissue slices occurs most rapidly with spleen and it is concluded that there is no relation between the power of an organ to break up (III) and its power to form (I) *in vitro*. H. D.

**Oxidation of indole in various organs of the rabbit.** J. GARCÍA-BLANCO and J. NACLE (Anal. Fis. Quím., 1935, 33, 105—108).—Indole is oxidised to indoxyl especially in the kidney. F. R. G.

**Kinetics of elimination of substances injected intravenously. (Creatinine.)** R. DOMINGUEZ, H. GOLDBLATT, and E. POMERENE (Amer. J. Physiol., 1935, 114, 240—254).—Creatinine introduced rapidly into the blood-stream of the dog is dispersed quickly into a large portion of the body-fluids (equiv. plasma vol.) from which it diffuses reversibly into the remainder (tissue vol.), until equilibrium is reached; it is excreted steadily by the kidneys before and after establishment of equilibrium. R. N. C.

**Clearance of hexamethylenetetramine in the dog.** R. F. PITTS (Amer. J. Physiol., 1936, 115, 706—710).—The clearance ratio of  $(CH_2)_6N_4$  (I) and xylose (II) in the normal dog is independent of the plasma-(I) concn.; hence (I) clearance itself is also independent of plasma-(I). Simultaneous clearances of (I) and (II) are practically identical and about 75% of the simultaneous clearance of creatinine. Phloridzin depresses all three clearances, that of (II) being altered least. R. N. C.

**Intestinal absorption of amino-acids.** R. HÖBER and J. HÖBER (Proc. Soc. Exp. Biol. Med., 1936, 34, 486—488).—The diffusion of various  $NH_2$ -acids and acid amides through the intestinal wall is not a simple function of mol. vol. but shows evidence of sp. selectivity. W. O. K.

**Absorption of cystine, methionine, and cysteine acid from intestinal loops of dogs.** J. C. ANDREWS, C. G. JOHNSTON, and K. C. ANDREWS (Amer. J. Physiol., 1936, 115, 188—193).—The rate of absorption is max. for methionine and min. for cystine. The amount absorbed in a given period varies with the amount introduced. The amount of  $NH_2$ -acid absorbed is the same, whether it is injected as free acid or Na salt; the amount of NaOH absorbed is independent of the  $NH_2$ -acid. R. N. C.

**Utilisation of glutathione in connexion with a cystine-deficient diet.** H. M. DYER and V. DU VIGNEAUD (J. Biol. Chem., 1936, 115, 543—549).—Oral or subcutaneous administration of glutathione

will support growth of rats on a cystine-deficient diet.

H. G. R.

**Synthesis of neutral fat by the intestine of diabetic dogs.** S. FREEMAN and A. C. IVY (Amer. J. Physiol., 1935, 114, 132—136).—Oleic acid (I) is absorbed from the intestine largely as neutral fat and phospholipin, showing that glycerol is available for fat synthesis in absence of insulin, and that phosphorylation of (I) is not impaired. The increases in cholesterol in the chyle of normal dogs are absent from that of depancreatized animals.

R. N. C.

**Ether-soluble lipin-phosphorus, lecithin, and cephalin distribution in the development of the chick.** O. E. KUGLER (Amer. J. Physiol., 1936, 115, 287—291).—Phospholipin metabolism reaches its highest stage between the 15th and 17th days of incubation. Lecithin and cephalin run parallel with each other, showing the same fluctuations as Et<sub>2</sub>O-sol. lipin-P during development, and maintain a ratio of approx. 3:1 in the yolk and the embryo fraction throughout incubation.

R. N. C.

**Transformations of adenosinetriphosphoric acid in muscle.** IV. Transformation of adenosinetriphosphoric acid in muscle of hibernating animals. O. FEINSCHMIDT (Biochem. Z., 1936, 286, 290—294).—During hibernation, the adenosinetriphosphoric acid (I) and P<sub>2</sub>O<sub>7</sub><sup>4-</sup> (II) contents of the muscle of the ground-squirrel *Citellus guttatus* are considerably decreased, (II) to a smaller extent than corresponds with the decrease of (I). Muscle then contains inorg. (II) and free adenylic acid (cf. this vol., 754).

P. W. C.

**Creatinuria induced by ingestion of glucose and fructose and by exercise.** J. HALDI and G. BACHMANN (Amer. J. Physiol., 1936, 115, 364—370).—Ingestion of glucose (I) and/or fructose (II) by men often causes excretion of creatine (III), whilst carbohydrate metabolism is increased. (II) induces a higher (III) excretion than (I) or (I)+(II). (III) excretion often follows exercise, particularly if this is preceded by ingestion of sugar, (II) again inducing the higher excretion; creatinine excretion is not affected.

R. N. C.

**Hexose phosphate metabolism of tumour extracts.** C. A. MAWSON (Biochem. J., 1936, 30, 1592—1597).—Lactic acid (I) is not produced from glucose by mouse tumour cell suspensions at 38° or 52°, with or without addition of glutathione (II). Small amounts of (I), not increased by the addition of (II), are produced from hexose diphosphate (III) at 38°; at 52°, larger amounts, considerably increased by the addition of (II), are produced. Dialysis lowers the activity of tumour extracts, which is restored by the addition of (II). The production of (I) from (III) at 52° is greatly reduced by kidney antiglyoxalase.

F. A. A.

**Glycogen and the metabolism of carbohydrate.** F. G. YOUNG (Lancet, 1936, 231, 237—242, 297—302).—Lectures.

L. S. T.

**Avian carbohydrate metabolism.** R. SPRAGUE and A. C. IVY (Amer. J. Physiol., 1936, 115, 389—394).—The blood-sugar (I) responses of normal and depancreatized ducks to insulin are similar.

Relatively large doses of adrenaline (II) are required to produce hyperglycemia, normal birds showing a greater response than depancreatized birds, suggesting that (II) and the sympathetic nervous system are of less importance in avian than in mammalian carbohydrate metabolism. Pituiratin does not affect (I). Liver-glycogen (III) is unaffected by depancreatization, and the (III) hydrolysate contains moderate quantities of lactic acid in both cases. The rate of disappearance of glucose from the blood *in vitro* is unaltered by depancreatization. Extracts of duck's pancreas contain an insulin-like substance.

R. N. C.

**Mechanism of carbohydrate breakdown in early embryonic development.** J. NEEDHAM, W. W. NOWINSKI, R. P. COOK, and K. C. DIXON (Nature, 1936, 138, 462—463).—The changes which sugar-like substances undergo in or under the influence of chick embryos of 4—6 days' incubation are summarised and compared with those effected by brain and muscle tissues. Glucose and mannose are the only sugars which give a steady, long-continuing glycolysis; fructose, and disaccharides even when phosphorylated, are unattacked. Lactic acid is quantitatively formed during glycolysis. The embryo does not glycolyse any combination of the P-containing intermediates. The Pasteur effect is very marked. The P distribution in various fractions of the aq. CCl<sub>3</sub>·CO<sub>2</sub>H extract differs from that obtained with muscle and brain preps.

L. S. T.

**"Hunger diabetes" and the utilisation of glucose in the fasting dog.** S. SOSKIN and I. A. MIRSKY (Amer. J. Physiol., 1935, 114, 106—109).—Sugar is utilised after evisceration by the normal fasting dog at the same rate as by the normal fed dog. The low R.Q. and other symptoms of "hunger diabetes" are due rather to increased gluconeogenesis than to lack of carbohydrate utilisation.

R. N. C.

**Effect of hypophysectomy on gluconeogenesis in the normal and depancreatized dog.** S. SOSKIN, I. A. MIRSKY, L. M. ZIMMERMAN, and N. CROHN (Amer. J. Physiol., 1935, 114, 110—118).—The hypophysectomised animal is unable, when its carbohydrate (I) stores are depleted and it is deprived of exogenous (I), to synthesise (I) from fat, but can derive it from protein.

R. N. C.

**Carbohydrate metabolism of the heart during pancreas diabetes.** H. E. HIMWICH, W. GOLDFARB, and J. F. FAZIKAS (Amer. J. Physiol., 1936, 114, 273—277).—The carbohydrate balance of the heart in both normal and diabetic dogs is positive; this explains the paradoxical storage of cardiac glycogen (I) if a diminished power to oxidise glucose is taken into consideration. The R.Q. of diabetic cardiac tissue is > 0.7, showing that non-fatty substances can be oxidised. O<sub>2</sub> consumption in presence of lactic acid is increased; its oxidation limits storage of (I). Diabetic cardiac tissue can still glycolyse.

R. N. C.

**Normal glucose tolerance curves, in the absence of insulin, in hypophysectomised depancreatized dogs.** S. SOSKIN, I. A. MIRSKY, L. M. ZIMMERMAN, and R. C. HELLER (Amer. J. Physiol.,

1936, 114, 648—652).—The occurrence of the normal glucose (I) tolerance curve is determined by a homeostatic reaction of the liver, whereby the supply of sugar to the blood is increased in response to the influx of exogenous (I). The rise in (I) stimulates this mechanism, whilst the pancreas and pituitary determine the (I) level at which it comes into play.

R. N. C.

**Intermediate metabolism of carbohydrates.** H. A. KREBS (Nature, 1936, 138, 288—289).—When added to animal tissues  $\text{AcCO}_2\text{H}$  disappears rapidly even in absence of  $\text{O}_2$ ; the products of the anaerobic oxidation are  $\text{AcOH}$ ,  $\text{CO}_2$ , and succinic acid. Changes which  $\text{AcCO}_2\text{H}$  undergoes in living cells are described. They are intermediate steps in the biological breakdown of carbohydrates.

L. S. T.

**Secretory metabolism of the salivary glands.** D. NORTHUP (Amer. J. Physiol., 1935, 114, 46—52).—Simultaneous stimulation of sympathetic and parasympathetic nerves to the submaxillary gland of the dog increases lactic acid (I) and decreases glycogen (II) and creatinephosphoric acid (III) in the gland. The changes produced by sympathetic stimulation alone are  $>$  those from parasympathetic stimulation alone, but  $<$  those from combined stimulation. Since breakdown of (II) and (III) to (I) occurs during salivary secretion, it is possible that the (II)–(III) mechanism is general for release of energy in tissues where work is done.

R. N. C.

**Metabolism of bacteria-free animals. II. Production and excretion of oxalic acid by guinea-pigs.** S. BORGSTRÖM (Skand. Arch. Physiol., 1936, 73, 63—66).—Bacteria-free and normal guinea-pigs excreted similar amounts of  $\text{H}_2\text{C}_2\text{O}_4$  up to the 15th day after birth, after which the normal animals' excretion remained const., whilst that of the sterile animals rose parallel with the growth curve and after 30 days was 6 times that of the controls.

NUTR. ABS. (m)

**Alcohol injected intravenously: effect of habituation on rate of metabolism.** H. W. NEWMAN and W. C. CUTTING (J. Pharm. Exp. Ther., 1936, 57, 388—393; cf. A., 1935, 1409).—Oral administration of 6.8 c.c. of  $\text{EtOH}$  per kg. per day for 13 months did not significantly increase the rate of oxidation of  $\text{EtOH}$  when injected intravenously into 3 dogs.

J. N. A.

**Relation of the urinary chloride rate to the plasma concentration before and after administration of sodium chloride.** E. M. MACKAY and L. L. MACKAY (Amer. J. Physiol., 1936, 115, 455—460).—When excretion of urine (rabbit) is high and urea formation directly related to blood-urea, urinary and plasma- $\text{Cl}'$  show no uniformity. If  $\text{NaCl}$  is administered in large doses to increase plasma- $\text{Cl}'$ , a curvilinear relationship tends to appear between urinary and plasma- $\text{Cl}'$ . There is a  $\text{Cl}'$  threshold for the rabbit.

R. N. C.

**Production of chloride-free solutions by the action of the intestinal epithelium.** R. C. INGRAHAM and M. B. VISSCHER (Amer. J. Physiol., 1936, 114, 676—680).— $\text{Cl}'$  is almost completely removed from solutions containing  $\text{SO}_4''$  placed in the lower ileum.  $\text{Na}_2\text{SO}_4$  becomes conc. in the intestine,

the increase of osmotic pressure of the cation due to exchange of  $\text{Cl}'$  for  $\text{SO}_4''$  causing an increase in  $\text{Na}'$ . The normal intestine is impermeable to  $\text{SO}_4''$ ; the movement observed is not, however, due to a simple Donnan equilibrium with  $\text{SO}_4''$  as the impermeable ion.  $\text{K}'$  substituted for  $\text{Na}'$  does not appreciably alter the movement of  $\text{Cl}'$ .

R. N. C.

**Distribution and storage of fluorine in tissues of the laying hen.** K. HAMAN, P. H. PHILLIPS, and J. G. HALPIN (Poultry Sci., 1936, 15, 154—157).—All normal tissues, except washed feathers and thyroid, contained F, in amounts decreasing in the order: bones, kidney and liver, muscle, fat. Vals. were increased by feeding raw rock phosphate or phosphatic limestone, bones being affected  $>$  soft tissues. In laying hens storage of F  $\propto$  the amount ingested.

A. G. P.

**Calcium changes in the plasma resulting from brief severe work and the question as to the permeability of the capillaries to calcium.** A. KEYS and L. ADELSON (Amer. J. Physiol., 1936, 115, 539—547).—Ca rises in plasma after brief severe exercise, reaches its max. in 1 min., and then declines logarithmically to reach its resting level in 30—70 min.; the changes are closely parallel to, but slightly  $>$ , those in plasma-protein. The mechanism of these changes is discussed with reference to "diffusible" Ca.

R. N. C.

**Calcium metabolism of laying hens.** H. J. DEOBALD, E. J. LEASE, E. B. HART, and J. G. HALPIN (Poultry Sci., 1936, 15, 179—185).—In individual hens blood-Ca remained substantially const. over a 36 hr. period. Deprivation of Ca resulted in a gradual decrease in the  $\text{CO}_2$ -free ash of egg shells and laying ceased in approx. 12 days. A portion of the skeletal Ca of hens may be utilised in shell formation. Subcutaneous injection of small amounts of parathormone into Ca-deficient hens had no effect on Ca metabolism, egg production, ash content of bones, or blood-Ca. Large injections increased blood-Ca.

A. G. P.

**Rate of bismuth absorption in experimental animals following oral administration.** G. E. CLARKE and H. F. MARSH (J. Pharm. Exp. Ther., 1936, 57, 399—409).—Bi in the form of K or Na Bi tartrate or  $\text{BiOCl}$  when administered orally to guinea-pigs is deposited in the liver, spleen, and kidney. In liver and spleen the highest concn. of Bi occurs after 24 hr. and in kidney between 12 and 48 hr. Bi administered to pregnant animals was found in the foetal liver and placenta, but not in the foetal kidney.

J. N. A.

**Magnesium excretion in dogs. Physiology of the colon. III.** R. NICOLAYSEN (Skand. Arch. Physiol., 1936, 73, 75—89).—Two dogs of const. wt. (8 kg.) and in N equilibrium on a Mg-free neutral diet excreted in the urine during 10 3-day periods 6—24 mg. of Mg, the faecal excretion being from 18 to 26 mg. These vals. were unchanged after the colon had been short-circuited and the ileum anastomosed with the rectum. In the colon the Mg excretion constituted only a small % of the total amount excreted by the whole gut and remained const. whether the dogs were on a diet deficient or

rich in Mg. Of parenterally injected Mg, 70—90% was excreted by the urine and none appeared in the colon or in the rest of the alimentary canal.

NUTR. ABS. (m)

**Metabolism of sulphur. II. Metabolism of sulphur and protein in infants and children.** A. BLAZZO (J. Physiol. Path. gén., 1936, 34, 120—135).—The urinary concn. and output of S and neutral S fraction per unit of body-wt. in infants were > in older children. Replacement of part of the (boiled or unboiled) mother's milk with cow's milk did not change the relative concns. of the S fractions. The total S in infant's faeces was very small and its concn. was the same as for a child. Of the S fractions, ethereal S was present in greatest concn. in the faeces of the child, whereas in infant's faeces neutral S was greater. In the fasting state the total S and S fractions of the blood-serum were the same for infants and older children. Inorg. S was 8—10 mg. per 100 ml. The ethereal S fraction was < the inorg.

NUTR. ABS. (m)

**Bone formation. I. Normal bone formation and the constitution of mineral reserves during development. II. Rickets in the growing rat.** A. ROCHE and I. GARCIA (Bull. Soc. Chim. biol., 1936, 18, 1014—1026, 1027—1040).—I. During ossification in the normal rat the ratio P/N of the femur and tibia diminishes slightly until the animals reach 25—30 g. wt. The ratio then increases to the original val. when the rats weigh 45 g., and after a short period when the val. is almost const., a steady increase takes place till the wt. reaches 150 g.

II. In young rats fed on a vitamin-D-deficient diet the femur and tibia show development of rachitic lesions until the 16th day. Spontaneous recovery then takes place, being complete after 55 days. These observations are associated with an increase in H<sub>2</sub>O and N and a decrease in P and the ratio P/N, this being followed in the period of apparent recovery by normal vals. for H<sub>2</sub>O and N, but low P. vals. A. L.

**Electrolyte changes in muscle during activity.** W. O. FENN and D. M. CORB (Amer. J. Physiol., 1936, 115, 345—356).—Stimulation of rat's muscles through the nerve causes exchange of about 15% of K<sup>+</sup> for Na<sup>+</sup>, and increases in H<sub>2</sub>O and extracellular NaCl, all these changes being reversed during recovery. Frog muscles lose K<sup>+</sup> only when stimulated directly.

R. N. C.

**Effect of fat on the  $p_H$  of the contents of the duodenum.** J. E. THOMAS and J. O. CRIDER (Amer. J. Physiol., 1936, 114, 603—608).— $p_H$  becomes neutral or slightly acid, probably through inhibition of gastric secretion and motility.

R. N. C.

**Biological action of radiations. Selectivity factors. I. Time factor.** J. PALACIOS and H. TELLEZ-PLASENCIA (Anal. Fis. Quím., 1934, 32, 677—681).—A theoretical study of the relative rates of destruction of normal and dividing cells.

F. R. G.

**Comparative effects of X-rays and neutrons on normal and tumour tissue.** J. H. LAWRENCE, P. C. ARBERSOLD, and E. O. LAWRENCE (Proc. Nat. Acad. Sci., 1936, 22, 543—557; cf. this vol., 632).—Per unit of ionisation produced, neutrons are three

times as effective as X-rays in causing the deaths of normal mice, and four times as effective in destroying sarcoma 180 *in vitro*. A marked fall occurs in the no. of white blood cells of mice exposed to either radiation, the min. occurring 4 days after irradiation.

F. A. A.

**Radiation sensitivity of "Photodyn."** G. KOEGL (Strahlenther., 1935, 54, 182—184; Chem. Zentr., 1935, ii, 3795).—"Photodyn," a hæmatoporphyrin prep., is active only in the light. Its therapeutic use and a series of radiation experiments are described; it is most sensitive to yellow light.

H. N. R.

**Liberation of an acetylcholine-like substance from surviving nerve fibres during electrical stimulation *in vitro*.** G. BERGAMI (Boll. Soc. ital. Biol. sperim., 1936, 11, 275—277).—Stimulation of nerve-fibre (dog's vagus or phrenic) in eserine-Ringer's solution produces a substance which resembles acetylcholine in its action on leech-muscle preps.

F. O. H.

**Survival of ascarid eggs after centrifuging.** H. W. BEAMS and R. L. KING (Science, 1936, 84, 138).—Centrifuging at  $1-4 \times 10^5 g$  does not kill eggs of *A. suum*. The killing of cells by centrifuging appears to be due to mechanical distortion or disruption rather than to a disturbance of the spatial relationship of their mol. parts.

L. S. T.

**Circulatory and visual effects of oxygen at three atmospheres pressure.** A. R. BEHNKE, H. S. FORBES, and E. P. MOTLEY (Amer. J. Physiol., 1936, 114, 436—442).

R. N. C.

**Effect of carbon monoxide on recovery of frog skeletal muscle.** J. B. HURSH (Amer. J. Physiol., 1936, 114, 625—634).—Excess O<sub>2</sub> consumption and recovery heat production of a stimulated muscle in air are decreased by placing in 79% CO and 21% O<sub>2</sub>. The rate of fatigue is the same. Lactic acid (I) concn. is not increased, and the effect of CO is not diminished by CH<sub>3</sub>I-CO<sub>2</sub>H, indicating that CO does not inhibit oxidation of (I).

R. N. C.

**Insensible water loss in relation to water ingestion in man.** J. F. HALL, jun., and G. S. MCCLURE (Amer. J. Physiol., 1936, 115, 670—678).—Rate of insensible perspiration is not increased by ingestion of H<sub>2</sub>O or 1% NaCl, or by injections of pituitrin, which, however, produce increases after H<sub>2</sub>O ingestion. The rate is increased by ingestion of sucrose, and lowered by dehydration >6% of the body-H<sub>2</sub>O.

R. N. C.

**The periodic system and biological action.** A. LENDLE (Chem.-Ztg., 1936, 60, 833—835).—A discussion.

**Physiological effects of mineral salts in natural waters.** C. B. POLLARD (J. Amer. Water Works Assoc., 1936, 28, 1038—1043).—A review.

**Skeletal changes in rats induced by a diet extremely poor in inorganic salts.** M. F. CLARKE, A. L. BASSIN, and A. H. SMITH (Amer. J. Physiol., 1936, 115, 556—563).

R. N. C.

**Sodium deficiency [in animals].** H. E. HIMWICH, J. F. FAZIKAS, and M. A. SPIERS (Proc. Soc.

Exp. Biol. Med., 1936, 34, 450—451).—Dogs, deprived of NaCl by intraperitoneal injection of glucose solutions, showed an increase in blood-urea and total solids, low serum-Cl', and a creatinuria.

W. O. K.

Colloidal potassium complexes.—See this vol., 1338.

Mechanism of the hæmatopoietic action of cobalt. J. M. ORTEN (Amer. J. Physiol., 1936, 114, 414—422).—Co increases the rate of formation of hæmoglobin and erythrocytes without diminishing the rate of cell destruction.

R. N. C.

Hypoglycæmic and other actions of phosphotungstic acid, phosphomolybdic acid, and allied substances. H. N. MUKHERJEE (Biochem. J., 1936, 30, 1583—1585).—0.2—0.3 g. of phosphotungstic (I), phosphomolybdic, molybdic, or silicotungstic acids, or Na tungstate, Na vanadate, or  $\text{NH}_4$  phospho-18-tungstate, fed by stomach tube to rabbits, has a hypoglycæmic effect comparable with 0.6 unit of insulin. Some of these, especially (I), have a diuretic action. The hypoglycæmic and diuretic actions of (I) were also tested on human diabetic patients, with positive results. The hypoglycæmia lasts longer than that produced by insulin. These substances behave towards benzidine and alkaline phenolphthalein like oxidising enzymes.

F. A. A.

Ætiological studies on formation of skin blisters in viscose workers. W. C. HUEPER (J. Ind. Hyg., 1936, 18, 432—447).—Blisters occurring on the fingers of doffers are caused by  $\text{CS}_2$  in the drip. Protective measures are indicated.

J. N. A.

Changes in skin after cauterisation with dichlorodiethyl sulphide and mineral acids. I. DORFFEL and POPPING (Virchow's Arch., 1935, 295, 1—20; Chem. Zentr., 1935, ii, 3945).

A. G. P.

Effect of dichlorodiethylsulphone on brain respiration. R. A. PETERS (Nature, 1936, 138, 327—328).—The effect of  $(\text{CH}_2\text{Cl}-\text{CH}_2)_2\text{SO}_2$  on brain respiration *in vitro* resembles in detail that of  $\text{CH}_2\text{I}-\text{CO}_2\text{H}$  (A., 1935, 262). The change of lactic acid to  $\text{AcCO}_2\text{H}$  (I) is unaffected, but the further oxidation of (I) is inhibited.

L. S. T.

Effect of 2:4-dinitrophenol (Thermol) on the gas metabolism of pigeons. Z. CATALDO (Boll. Soc. ital. Biol. sperim., 1932, 7, 767—770; Chem. Zentr., 1935, ii, 3792).—Injection of 2:4-dinitrophenol (I) (<5 mg. per kg.) increases  $\text{O}_2$  consumption. Atropine has little influence on this action although the birds become less resistant. During the action of (I) the R.Q. indicates that sugar is first consumed and when this process is well advanced fats are affected.

A. G. P.

Influence of temperature on stimulation of oxidation by dinitro-, dihalo-, and trihalo-phenols. M. E. KRAHL and G. H. A. CLOWES (Proc. Soc. Exp. Biol. Med., 1936, 34, 567—569).—The stimulating action of 4:6-dinitro-*o*-cresol (I) on the eggs of *Arbacia punctulata* and *Nereis limbata* is max. at concns. of  $4-8 \times 10^{-6}M$ , independently of the temp. The abs. increase is greatest and the relative increase least at the higher temp. The

optimum % increase in  $\text{O}_2$  consumption of rat kidney slices in presence of 2:4:5-trichloro-, 2:4-dichloro-, and 2:4:6-tri-iodo-phenol and (I) at  $20^\circ$  is  $>$  at  $37^\circ$ .

W. O. K.

Toxicity and action on guinea-pigs of synthetic *l*-camphor. R. HAZARD and R. LARDE (J. Pharm. Chim., 1936, [viii], 24, 118—120).—The toxicities of the three stereoisomeric camphors are in the order  $l > dl > d$ .

W. O. K.

Derivatives of  $\beta$ -amino- $\alpha$ -hydroxy- $\alpha$ -phenylpropionic acid [pharmacological properties].—See this vol., 1377.

Biological analogy of bile acids and sterols. Influence of bile salts on growth and morphogenesis of tadpoles. D. ZIMMET (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 136—137).—Na glyco- and tauro-cholate accelerate growth and morphogenesis in the same way as cholesterol.

G. H. B.

Influence of amino-acids on blood-sugar regulation in dogs with Eck fistulæ. L. KESZTYUS and J. MARTIN (Arch. exp. Path. Pharm., 1936, 182, 514—520).—Arginine, cystine, and tyrosine increase the blood-sugar of dogs with fistulæ. The inactivity of these  $\text{NH}_2$ -acids in normal dogs is due to rapid decomp. in the liver. Injection of glycine into normal dogs produces a hyperglycæmia followed after 1 hr. by a hypoglycæmia, probably due to adrenaline- followed by a compensatory insulin-action.

F. O. H.

Role of choline in removable shock in the guinea-pig's heart. S. WENT and K. LISSAK (Arch. exp. Path. Pharm., 1936, 182, 509—513).—During anaphylactic shock (ox serum) in the isolated, surviving heart, perfusates acquire a slowing action (inhibited by atropine) on the frog's heart but are inactive on leech preps.; acetylation of the perfusates produces a typical acetylcholine activity (frog's heart, leech). The choline content (to which the behaviour of the heart during shock is due) of the heart decreases after shock but the histamine content remains unchanged.

F. O. H.

Comparative effects of pancreas and choline on blood-cholesterol of depancreatized dogs maintained with insulin. I. L. CHAIKOFF and A. KAPLAN (Proc. Soc. Exp. Biol. Med., 1936, 34, 413—416).—Oral administration of raw pancreas to depancreatized dogs on a suitable basic diet increased their abnormally low blood-cholesterol, but choline in quantities  $>$  the amounts present in the lecithin of the raw pancreas was without appreciable effect.

W. O. K.

Effect of acetylcholine on the blood-flow through the stomach and legs of the rat. H. NECHELES, R. FRANK, W. KAY, and E. ROSENMAN (Amer. J. Physiol., 1936, 114, 695—699).

R. N. C.

Blood-amylase response to acetyl- $\beta$ -methylcholine chloride in rabbits. A. SCHIFFRIN, L. TUCHMAN, and W. ANTOPOL (Proc. Soc. Exp. Biol. Med., 1936, 34, 539—540).—In rabbits there is usually but not always a marked increase in blood-amylase after intramuscular injection of acetyl- $\beta$ -methylcholine chloride.

W. O. K.

Chemical transmission of vagal effects to the small intestine. H. BUNTING, W. J. MEEK, and C. A. MAASKE (Amer. J. Physiol., 1935, 114, 100—105).—Vagal stimulation results in the formation of an acetylcholine-like substance in the splanchnic area. It comes partly from the small intestine, from which it can be removed by perfusion.

R. N. C.

Action of the nitrogenous bases of the gastric juice on blood-pressure, pancreatic secretion, and flow of bile. S. A. KOMAROV (Amer. J. Physiol., 1936, 115, 604—609).—The arginine fraction from canine gastric juice exhibits a histamine-like action on blood-pressure and pancreatic secretion. The lysine fraction increases blood-pressure and stimulates pancreatic and bile flow. The histidine fraction is without effect.

R. N. C.

Physiological importance in nutrition of methods of preparation of foodstuffs. I. Influence of roasting with coffee, coffee substitutes, and similar products. B. BLEYER, W. DIEMAIR, F. FISCHLER, K. TAUFEL, F. ARNOLD, and H. THALER (Biochem. Z., 1936, 286, 408—428).—The production during roasting of coffee, chicory, wheat, etc. of histamine-like substances is detected chemically and confirmed by biological test on guinea-pig's intestine.

P. W. C.

Action of tyramine in increasing blood pressure in pallid hypertension. H. A. HEINSEN and H. J. WOLF (Z. klin. Med., 1935, 128, 213—222; Chem. Zentr., 1935, ii, 3945).—In chronic nephritis and in malignant nephrosclerosis, tyramine occurs in the blood. It is formed in kidneys by decarboxylation of tyrosine.

A. G. P.

Humoral anti-adrenaline regulation. B. TARRAS-WAHLBERG (klin. Woch., 1935, 14, 793—795; Chem. Zentr., 1935, ii, 3789).—Rabbit and guinea-pig blood contains a substance which causes contraction of the small intestine of guinea-pigs and a decreased blood-pressure in atropinised rabbits. It is dialysable and more resistant to boiling 0.5N-HCl than to 0.5N-NaOH. The activity of the blood is increased by pre-injection of adrenaline.

Anti-pernicious anaemia principle in stomach. I. Method to improve stomach preparations. E. A. GREENSPON (J. Amer. Med. Assoc., 1936, 106, 266—271).—No response was produced by 40 g. of ventriculin mixed with 200 ml. of H<sub>2</sub>O, 0.1 g. of pepsin (I), and dil. HCl and incubated at 38° overnight, when fed to a patient with pernicious anaemia in relapse. Depepsinised gastric mucosa produced a marked reticulocyte response in a case of pernicious anaemia. The activity was destroyed by incubation with (I) and HCl, but not with HCl alone. Since a reticulocyte response was produced in a case of pernicious anaemia by daily oral administration of 250 ml. of normal gastric juice freed from (I) and since a single intramuscular injection of the concentrate of 540 ml. of normal gastric juice freed from (I) produced in 2 cases of pernicious anaemia reticulocyte crises of 24.5 and 21% and increases in the red cell count of 1.8 and 1.6 millions, respectively, it is concluded that (I) destroys the active principle of

the mucosa and that the presence of an "extrinsic factor" is unnecessary in the production of the principle.

NUTR. ABS. (m)

Comparison of the action of insulin and of the hypoglycaemic principle of the jejunum in the pancreatectomised dog. F. RATHERY, A. CHOAY, and P. DE TRAVERSE (Compt. rend., 1936, 203, 206—208).—Equiv. doses (tested on a rabbit) of an extract (cf. this vol., 1158) of the jejunum of the ox and of insulin injected intramuscularly produce almost identical decreases in the concn. of the blood-sugar of a depancreatized dog; the duration of action of the former is more prolonged.

J. L. D.

Comparative effects of barbituric acid derivatives on isolated heart. R. L. JOHNSTON (J. Pharm. Exp. Ther., 1936, 57, 333—336).—Perfusion of the isolated turtle heart with the Na salts of the following barbituric acid derivatives (concn. 0.0005M) in Ringer's solution at  $p_{H}$  7.2—7.4 showed that the toxicity decreased in the order: oral, amytal, nembutal, evipal, phenobarbital, phanodorm, barbital.

J. N. A.

Detoxification of dendrobine by "sodium amytal." K. K. CHEN and C. L. ROSE (Proc. Soc. Exp. Biol. Med., 1936, 34, 553—554).—Na amytal administered to rabbits poisoned by dendrobine hydrochloride can antidote up to 5 min. lethal doses of the alkaloid.

W. O. K.

Anæsthetic properties of "sodium ethylpentyl-malonylthiourea." M. G. MULINOS (Proc. Soc. Exp. Biol. Med., 1936, 34, 506—507).—Na ethylmalonylthiobarbiturate (Na pentothal) has a pharmacological action resembling its O-analogue (Na pentobarbital).

W. O. K.

Elimination of cobalt in the bile. F. CAUJOLLE (Bull. Soc. Chim. biol., 1936, 18, 1081—1090).—In dogs under chloralose anaesthesia 3.2% of aq. CoCl<sub>2</sub> injected intravenously is eliminated rapidly in the bile. With a permanent fistula and no anaesthetic the elimination is less rapid.

A. L.

Anæsthetic effects of furan derivatives. V. E. HENDERSON and A. H. R. SMITH (J. Pharm. Exp. Ther., 1936, 57, 394—398).—Furan and its H<sub>4</sub>, Me<sub>2</sub>, and dimethyltetrahydro-derivatives are of no clinical val. as anaesthetics; the first three produce fatty changes in the liver, a possible mechanism of which is discussed.

J. N. A.

Fishes as test subjects for the biological action of various substances and for the determination of the nature of urease. N. KAWAMOTO (J. Biochem. Japan, 1936, 23, 267—298).—Saponin, adrenaline, and atropine are readily absorbed through the gills of carp in which they exert their characteristic action. The action on the blood-sugar of normal and dialysed aq. insulin thus administered indicates the presence of hyper- and hypo-glycaemic fractions. The gills are impermeable to normal urease preps. but are permeable to tryptically digested preps., whilst on prolonged digestion the activity disappears; the data indicate that urease has a polypeptide structure.

F. O. H.

Destruction of cardio-active glucosides by acids and alkalis. F. T. VON BRÜCKE (Arch. exp.

Path. Pharm., 1936, **182**, 444—451).—Data of the action of 0.05—0.1*N*-HCl and -NaOH and of 0.1%  $\text{Na}_2\text{CO}_3$  at 37° on *Digitalis* glucosides, *g*- and *k*-strophanthin, and cymarin are tabulated. The glucosides are not affected by trypsin or pepsin but are inactivated at gastric acidity and, very slowly, at duodenal alkalinity; decomp. occurs with 0.05—0.1*N*-NaOH at 37°. F. O. H.

Decurarising substances. A. ROSENBLUETH, D. B. LINDSLEY, and R. S. MORISON (Amer. J. Physiol., 1936, **115**, 53—68). R. N. C.

Esmodil, a new vagus-stimulant. G. HECHT (Klin. Woch., 1935, **14**, 957—958; Chem. Zentr., 1935, ii, 3945).—Esmodil,  $\text{CH}_2\text{C}(\text{OMe})\text{CH}_2\text{NMe}_3\text{Br}$ , is not enzymically decomposed in the organism and is stable in dil. alkali but not in dil. acid. Physiological activities are described. A. G. P.

Pharmacological action of coriamyrtin. (A.) A. H. MALONEY. (B.) E. E. SWANSON and K. K. CHEN (J. Pharm. Exp. Ther., 1936, **57**, 361—375; 410—418).—(A) The min. lethal doses of coriamyrtin (I) for the frog, rabbit, and rat are 10, 0.4, and 1 mg. per kg., respectively. (I) increases the blood-sugar of the rabbit by 13%, has very little effect on blood pressure, but powerfully stimulates respiration. (I) is very toxic, and resembles picrotoxin in its action, which is of very short duration.

(B) (I) abolishes anaesthesia and wakens animals under the influence of a barbiturate. Na amytal is far more effective in combating (I) poisoning than is (I) in counteracting-Na amytal poisoning. J. N. A.

Stereoisomeric nature of oxidation and fermentation. G. A. GAUSE (Nature, 1936, **138**, 245—246).—The fermentations of glucose by different micro-organisms are more strongly depressed by *l*- than by *d*-nicotine, but the oxidations are more strongly depressed by the *d*-form. In green algae oxidations are direct and sensitive to *d*-nicotine poisoning, but in the frog, fowl, green linnet, etc. oxidations are coupled with fermentations and are more sensitive to the action of *l*-nicotine. The action of the optically-active nicotines on the metabolism of mouse tissue is also described. L. S. T.

Effect of atropine and pilocarpine on the emptying time of the human stomach. R. C. HERRIN (Amer. J. Physiol., 1936, **115**, 104—112). R. N. C.

Effect of atropine and pilocarpine on gastric emptying in normal and denervated dogs. R. C. HERRIN, A. RABIN, and E. A. BACHHUBER (Amer. J. Physiol., 1936, **115**, 113—120). R. N. C.

Blood-sugar level after administration of pilocarpine, atropine, and acetylcholine. M. C. HRUBETZ (Amer. J. Physiol., 1936, **114**, 551—554).—Pilocarpine (I) raises blood-sugar (II) in rats, the max. occurring in 15 min. Atropine lowers (II), the max. effect occurring in 90 min., and inhibits the effect of (I). Acetylcholine lowers (II), the min. val. being reached in 20 min. R. N. C.

Action of drugs on choline esterase of brain. F. BERNHEIM and M. L. C. BERNHEIM (J. Pharm. Exp. Ther., 1936, **57**, 427—436).—Choline esterase

(I) is greatly inhibited by very small concns. of morphine and apomorphine, and it is suggested that these and possibly other centrally acting drugs may cause accumulation of acetylcholine in brain by inhibiting (I). In most animals the activity of (I) per mg. of dry wt. is greater in the brain than in the serum. J. N. A.

Comparative action of methylephedrine and ephedrine. I. Systemic effects. II. Bronchial effects. C. PAK and B. E. READ (Quart. J. Pharm., 1936, **9**, 235—255, 256—267).—I. The circulatory effect of methylephedrine (I) is similar to but < that of ephedrine (II). (I) has an inhibitory effect (probably due to pressor action) on respiration but not the secondary accelerating action of (II). (I) does not stimulate the central nervous system, whilst the toxic effect on rabbits and dogs and dilation of the pupil are < those due to equal doses of (II). Other differences in pharmacological action are described.

II. The bronchial dilator effect of (I) in anaesthetised cats is slower than, but the intensity and duration are approx. equal to, that of (II). (I) and (II) in concns. of 10<sup>-2</sup>—10<sup>-3</sup>% respectively dilate and constrict the isolated bronchioles. F. O. H.

Substituted hydroxybenzyl alcohols.—See this vol., 1374.

Excretion of "skiodan," "diodrast," and "hippuran" by the dog. K. A. ELSOM, P. A. BOTT, and E. H. SHIELDS (Amer. J. Physiol., 1936, **115**, 548—555).—Skiodan excretion is independent of its concn. in the plasma, and consistently < that of creatinine (I) by approx. 10%. Diodrast and hippuran excretions depend on their concns. in the plasma. Their clearances are approx. equal to that of (I) at high but greater at low plasma-I. R. N. C.

Effect of various poisons on the movement of chloride against concentration gradients from intestine to plasma. R. C. INGRAHAM and M. B. VISSCHER (Amer. J. Physiol., 1936, **114**, 681—687).—Removal of Cl<sup>-</sup> in presence of  $\text{SO}_4^{--}$  is abolished by  $\text{Na}_3\text{AsO}_3$ , NaF,  $\text{H}_2\text{S}$ ,  $\text{HgCl}_2$ , and NaCN, in presence of which Cl<sup>-</sup> moves into the intestine; the increases in  $[\text{Na}^+]$  and  $[\text{SO}_4^{--}]$  are also abolished or reversed. Impermeability of the intestinal epithelium to bi- or multi-valent anions is apparently a condition for its performing osmotic work on Cl<sup>-</sup>. R. N. C.

[Pharmacological] action of arsenic and antimony. H. A. OELKERS and E. VINCKE (Arch. exp. Path. Pharm., 1936, **182**, 499—503).—The *in-vivo* (rabbits) reduction of oxalacetic to fumaric acid is inhibited by  $\text{KAsO}_3$  and K Sb tartrate (cf. Szent-Gyorgyi *et al.*, A., 1935, 1406), which also diminish the  $\text{O}_2$  consumption of liver tissue *in vitro*. Thus the toxic action of As and Sb is mainly due to disturbances of tissue- and organ-metabolism. F. O. H.

Influence of vitamin deficiency on the resistance of rats to neoarsphenamine, mercurochrome, pernocton, and insulin. R. WIEN (Quart. J. Pharm., 1936, **9**, 268—297).—The resistance to the toxicity of the three drugs is diminished by deficiency of vitamin-A, -B complex, or -D; that to insulin, as indicated by the blood-sugar curve after injection

of 0.5 unit per kg., is unaltered by deficiency of -A or -D whilst with B-avitaminosis, rats (which have normal fasting blood-sugar vals.) are more sensitive owing to a retardation in the recovery process.

F. O. H.

**Antidotal action of magnesium, hydrazine, and phenylhydrazine thioacetates, and hydrazine sulphate in mercurial poisoning.** G. DE NITO (Boll. Soc. ital. Biol. sperim., 1936, 11, 323—324).—Enteral, but not parenteral, administration has a significant antidotal action.

F. O. H.

**Limitation of fluorine toxicosis in the rat with aluminium chloride.** G. R. SHARPLESS (Proc. Soc. Exp. Biol. Med., 1936, 34, 562—564).—The toxic effect of NaF *per os* on the growth and teeth of young rats is antagonised by the addition to the diet of small quantities of  $AlCl_3$ .

W. O. K.

**Poisoning by vapours of beryllium oxyfluoride.** I. GELMAN (J. Ind. Hyg., 1936, 18, 371—379).—The toxic effects in man include fever followed after 2—5 days by lung lesions. The symptoms differ from those observed in cases of poisoning by F, HF,  $SO_2$ , or Be oxyfluoride in the form of dust.

J. N. A.

**Lead absorption in man. III. Blood-pressure observations.** E. L. BELKNAP (J. Ind. Hyg., 1936, 18, 380—390).—The average blood pressures of 81 workers with a heavy Pb absorption varied within normal limits, but tended to decrease slightly over a period of 1—5 years. There was no significant increase in systolic or diastolic pressure.

J. N. A.

**Lead in muscle and skin of cattle showing saturnism.** KOHN-ABREST (Bull. Acad. vet. France, 1936, 9, 122—123).—Muscles from 3 cattle slaughtered on account of saturnism contained only traces of Pb, but the skins contained 25—40 p.p.m., vals. similar to those reported in fatal cases of saturnism in human beings.

NITR. ABS. (*m*)

**Toxicology of selenium. I. Distribution of selenium in acute and chronic selenium poisoning. II. Urinary excretion of selenium.** H. C. DUDLEY (Amer. J. Hyg., 1936, 23, 169—180, 181—186).—I. In acute or chronic poisoning induced by feeding inorg. or org. Se compounds Se was found throughout the whole organism. The Se was distributed by the blood, being held chiefly in a protein-like complex. The serum, plasma, and fibrin did not contain Se, but it was present in the centrifuged corpuscles and the clot. It was largely deposited in the liver, kidneys, and spleen in acute cases and in the liver and kidneys in chronic cases. The amounts present in the bile and urine indicated that excretion was mainly by hepatic and renal routes. In the urine the Se was present as an  $Et_2O$ -sol., volatile compound. In chronic cases in pigs, 8—20 p.p.m. of Se were found in the hoofs.

II. The urine of men engaged in or near the extraction and processing of Se from electrode slimes in Cu refinery contained up to 0.069 p.p.m. of Se. The urinary Se in different individuals showed no correlation with the intensity of the symptoms.

NUTR. ABS. (*m*)

**Monstrosities produced by the injection of selenium salts into hens' eggs.** K. W. FRANKE, A. L. MOXON, W. E. POLEY, and W. C. TULLY (Anat. Rec., 1936, 65, 15—22).—The monstrosities resemble those produced when the hens are fed on wheat containing Se. As, F, and Pb in sublethal doses have no such action.

R. N. C.

**Inhibiting effect of sulphur in selenised soil on toxicity of wheat to rats.**—See B., 1936, 1011.

**Toxicological detection of hydrocyanic acid. Detection of poisoning by very small amounts of hydrocyanic acid.** P. R. ORELLA (An. Farm. Bioquim., 1935, 6, 1—11; Chem. Zentr., 1935, ii, 3804).—HCN is best fixed for toxicological analyses by means of  $AgNO_3$ . The formation of HCN in normal tissues by putrefaction or by the action of  $H_2SO_4$ — $H_2CrO_4$  does not occur.

J. S. A.

**Toxicity of dioxan.** H. H. SCHRENK and W. P. YANT (J. Ind. Hyg., 1936, 18, 448—460).—A resumé of work by various investigators. Animal experiments show that the toxicity of dioxan when absorbed through the skin, inhaled, ingested, or given by subcutaneous or intravenous injection is comparatively low, but large doses cause serious harm, the principal damage being to the kidneys and liver.

J. N. A.

**Toxicology of *Deris*.**—See B., 1936, 1013.

**Lactucarium. II. Enzymes of the sap of *Lactuca virosa*.** K. H. BAUER and K. BRUNNER (Pharm. Zentr., 1936, 77, 598—601; cf. A., 1929, 1181).—The fresh sap darkens unless placed immediately in 96% EtOH. The EtOH ppts. amongst other substances two oxidases, a tyrosinase and a lacase, which are almost or entirely absent from the commercial dried sap (lactucarium).

R. S. C.

**Enzymes in ontogenesis (Orthoptera). II. The indophenol oxidase.** J. H. BODINE and E. J. BOELL (J. Cell. Comp. Physiol., 1936, 8, 213—230).—The indophenol oxidase (I) content of grasshopper eggs has been determined throughout development. The  $CN'$ -sensitive respiratory mechanism of the eggs is dependent on, whilst (I) activity is independent of, organisation in the cells. Respiration during diapause is insensitive to  $CN'$ , and is unaffected by grinding. As (I) activity shows no diminution during this period, there can be no relation between the normal functioning of (I) and its action in the *in-vitro* oxidation of  $p$ - $C_6H_4(NH_2)_2$ .

E. A. H. R.

**Oxidation product of pyrocatechol when oxidised by means of tyrosinase.** H. WAGREICH and J. M. NELSON (J. Biol. Chem., 1936, 115, 459—465).—Two O atoms are concerned in the oxidation of  $o$ - $C_6H_4(OH)_2$  (I) in the presence of tyrosinase (II) over the  $p_H$  range 4.3—8. If the reaction is carried out in the presence of  $NH_2Ph$ , a dianilinobenzoquinone (III) is formed, and 3 O are used, over the  $p_H$  range 4.3—7. If  $NH_2Ph$  is added to the oxidised (I), (III) is formed, one O being consumed; this reaction is catalysed by (II). The data indicate that the initial oxidation of (I) involves 2 O per mol.

F. A. A.

**Peroxidases. III. Potentiometric determination of activity.** B. B. DEY, S. RENGACHARI, and M. V. SITHARAMAN (J. Indian Chem. Soc., 1936,

13, 390—398).—The titration of mixtures of quinol and  $\text{H}_2\text{O}_2$  against  $\text{Ce}(\text{SO}_4)_2$  cannot be followed potentiometrically (cf. A., 1929, 783; 1930, 727) although  $\text{H}_2\text{O}_2$  can be determined alone in  $\text{HCl}$  or  $\text{AcOH}$ . In determining the peroxidase (I) concn. in plant sap (A., 1931, 1455) this method cannot be used because the reducing substances in sap are oxidised.  $\text{Na}_2\text{S}_2\text{O}_3$  and  $\text{K}_2\text{Cr}_2\text{O}_7$  can be employed successfully to determine quinol potentiometrically and hence to arrive at the (I) concn. J. L. D.

**Poisoning with copper and reactivation in enzymic oxidation-reduction.** B. ANDERSSON (Z. physiol. Chem., 1936, 242, 205—209).—Although partly purified cozymase (I), xanthine, and uric acid reactivate the Schardinger enzyme system after poisoning with  $\text{CuSO}_4$  (cf. Wagner-Jauregg *et al.*, this vol., 895), no reactivation is produced by highly purified (I). W. McC.

**Catalytic action of lactoflavin-5'-phosphoric acid. Synthesis of the yellow enzyme.** R. KUHN and H. RUDY (Ber., 1936, 69, [B], 1974—1977).—Synthetic lactoflavin-5'-phosphoric acid reacts in neutral solution with the colloidal carrier of Warburg's yellow enzyme forming a non-fluorescent, non-dialysable chromoprotein resolved into its components by dil. acid. The product catalyses the oxidation of the Neuberg or Robison ester, measured by decolorisation of methylene-blue or absorption of  $\text{O}_2$ , in exactly the same manner as the natural material. The theory that an enzyme consists of a colloidal carrier and a chemically active group is thus strongly supported and the very sp. type of union is shown by the necessity for  $\cdot\text{PO}(\text{OH})_2$  at 5' and the flavin nucleus and  $\text{NH}$  at 3 for partial union with the carrier.

H. W.

**Components of dehydrogenase systems. XIII. Non-identity of alcohol- and triosephosphoric acid-apodehydrogenases.** H. VON EULER, E. ADLER, and S. KYRNING (Z. physiol. Chem., 1936, 242, 215—224; cf. this vol., 1150).—The apodehydrogenase (I) obtained from yeast maceration juice by fractional pptn. with  $(\text{NH}_4)_2\text{SO}_4$ , and supplemented with cozymase (II) and flavin enzyme, specifically dehydrogenates  $\text{EtOH}$  anaerobically [methylene-blue (III) as acceptor] but has no action on dihydroxyacetonephosphoric acid (IV). Hence (I) of  $\text{EtOH}$  is not identical with (I) of (IV) although both always occur together in non-purified enzyme preps. Both apodehydrogenases combine specifically with (II), which carries  $\text{H}$  from the donor to the acceptor system. Decolorisation of (III) with hexosediphosphoric acid as substrate occurs only when zymohexase and (I) of (IV) are present together. (I) specificity probably extends to triosephosphoric acids other than (IV) and hence is significant for the oxidation-reduction mechanism of alcoholic fermentation. W. McC.

**Enzymic dehydrogenation of trideuteroacetic acid.** R. SONDERHOFF and H. THOMAS (Naturwiss., 1936, 24, 570).—The oxidation of  $\text{CD}_3\cdot\text{CO}_2\text{Na}$  by  $\text{O}_2$  in presence of yeast cells proceeds at  $\frac{1}{2}$  of the rate observed with  $\text{NaOAc}$ . In both cases some of the acetate is incorporated into the cells as carbohydrate and fat, whilst succinic acid is also formed. During

the oxidation of  $(\text{CD}_3\cdot\text{CO}_2)_2\text{Ba}$  citric acid is formed. The succinic acid is not pure  $(\text{CD}_2\cdot\text{CO}_2\text{H})_2$ , but some replacement of  $\text{D}$  with  $\text{H}$  occurs. Similarly the citric acid contains a lower ratio of  $\text{D}/\text{H}$  than corresponds with  $\text{HO}\cdot\text{C}(\text{CD}_2\cdot\text{CO}_2\text{H})_2\cdot\text{CO}_2\text{H}$ . This confirms the theory of Wieland and Sonderhoff. W. O. K.

**Amylase system of rice grain during ripening and germination.** K. V. GIRI and A. SREENIVASAN (Nature, 1936, 138, 406—407).—Rice grain contains both  $\alpha$ - and  $\beta$ -amylases, which are differentiated by their hydrolysis of amyloamylose and by their  $p_{\text{H}}$  optima at 7.0 and 4.6, respectively. Both enzymes are present in dormant seed, largely in a condition not extractable by  $\text{H}_2\text{O}$ , but extractable in an active state by  $\text{PO}_4'''$  buffer at  $p_{\text{H}}$  7.0.  $\alpha$ -Amylase becomes inactive as ripening advances and then active again during germination. The view that amylase arises only during germination of the grains (A., 1933, 1343) is untenable. L. S. T.

**Enzymic studies on cereals. V. Saccharifying amylase of rice. VI. Saccharifying amylase of well-cleaned rice.** G. YAMAGISHI (J. Agric. Chem. Soc. Japan, 1936, 12, 783—792, 793—799).—V. The optimum  $p_{\text{H}}$  of the saccharifying amylase (I) (obtained by extraction with  $\text{H}_2\text{O}$  at approx.  $0^\circ$  for 10 hr.) from unhusked and uncleaned rice and rice bran are 5.0, 4.7, and 6.6, respectively. Purification by dialysis or pptn. with  $\text{EtOH}$  moves the optimum more to the acid side. The optimum temp. for (I) is  $45^\circ$ . (I) is heat-sensitive.

VI. The optimum  $p_{\text{H}}$  vals. of (I) extracted from well-cleaned rice flour with  $\text{NaCl}$  or papain solutions, and then purified by dialysis or pptn. with  $\text{EtOH}$ , are 4.5 and 4.3, respectively. In the outer part of the grain nearly all of (I) is readily sol. in  $\text{H}_2\text{O}$ , but in the inner part it is present in an insol. form as (I)-zymogen. J. N. A.

**Inulinase.** N. K. IYENGAR and M. SREENIVASAYA (Proc. Indian Acad. Sci., 1936, 4, B, 171—177).—Active preps. of inulinase (I) are obtained from species of *Aspergillus* growing on an artichoke medium.  $\text{PO}_4'''$  stimulates the production of (I) by the mould. The preps. may be dried by  $\text{COMe}$ , and (I) is extracted from the dried material by  $\text{PhMe}$ -saturated  $\text{H}_2\text{O}$ . The content and activity of (I) in dried preps. and extracts are directly related to their  $\text{P}$  but not to their total or  $\text{NH}_4\text{-N}$  contents. A. G. P.

**Maltase activity of the blood-serum of various species.** R. H. BARNES and E. M. MACKEY (Amer. J. Physiol., 1936, 114, 534—537).—Sera from a no. of species show maltase activity, which explains why insulin hypoglycaemia is relieved by maltase or glycogen in these species only. R. N. C.

**$\beta$ -Glycuronosidase. III, IV.** G. OSHIMA (J. Biochem. Japan, 1936, 23, 305—311, 311—318; cf. A., 1935, 402).—III. The enzyme is prepared from autolysed extracts of ox spleen by adsorption on kaolin at  $p_{\text{H}}$  2.6—4.4 and elution with  $M/15\text{-Na}_2\text{HPO}_4$ .

IV. The optimum  $p_{\text{H}}$  is 5.0—5.2 with menthol glycuronate in  $\text{OAc}'$  buffer as substrate, the reaction being unimol. and having an average temp. coeff. of 2.66 at  $30\text{—}45^\circ$  and a heat of inactivation of 36.34

kg.-cal. Ultra-violet irradiation inhibits whilst addition of neutral salts accelerates the hydrolysis. The inhibitory action of malic, tartaric, and citric acids and the accelerating action of  $\text{AcOH}$ ,  $\text{EtCO}_2\text{H}$ ,  $\text{Pr}^n\text{CO}_2\text{H}$ , and lactic acid are correlated with the presence or absence of  $\beta\text{-OH}$ . F. O. H.

**Glucosulphatase, an enzyme decomposing sulphuric esters of sugars.** T. SODA (J. Fac. Sci. Tokyo, 1936, I, 3, 149—222).—Data indicating the content of glucosulphatase (A., 1933, 534), phosphatase, and phenolsulphatase in various classes of molluscs are tabulated. Glucosulphatase (optimum  $p_{\text{H}}$  approx. 5; reaction const. of purified preps. given) has a temp. coeff. of approx. 2 over the range  $15\text{--}30^\circ$ , is rapidly inactivated at  $80^\circ$ , and is inhibited to varying extents by sugars and their derivatives (A., 1933, 749; 1934, 560). The physiological role of the enzyme is discussed (see also A., 1934, 520; this vol., 378). F. O. H.

**Reduction of cozymase.** E. ADLER, H. HELLSTROM, and H. VON EULER (Z. physiol. Chem., 1936, 242, 225—249; cf. this vol., 1150).—Cozymase (I) is converted by alkaline  $\text{Na}_2\text{S}_2\text{O}_4$  into a yellow substance (II) (absorption max. at  $360\text{ m}\mu$ ) which is quantitatively reconverted into (I) on neutralising or acidifying.  $\text{Na}_2\text{S}_2\text{O}_4$  at  $p_{\text{H}}$  7.5—8.0 and sp. apodehydrogenase (III) in presence of a H donor convert (I) into dihydrocozymase (IV) with intermediate transient production of (II). When (IV) is acidified 20% is reconverted into (I) and 80% into an inactive substance. (IV) is completely reconverted into (II) by flavin enzyme in presence of  $\text{O}_2$  and by sp. (III) in presence of H acceptor (MeCHO). (I) is not reduced by Zn in 0.1N-NaOH but is rapidly attacked in N-NaOH with production of a yellow colour. (IV) is not attacked by 0.1N-NaOH at  $100^\circ$  in 30 min. but is slowly reconverted into (I) on keeping, the  $p_{\text{H}}$  optimum for the change being 6. (II) rapidly reduces methylene-blue and  $\text{AgNO}_3$ , whereas (IV) reduces  $\text{AgNO}_3$  only very slowly. Possibly the reduction of (I) to (IV) takes place at the N:C linking which joins the  $\text{C}_5\text{H}_5\text{N}$  group to the rest of the mol. This linking is probably the only one in the mol. which is unstable to alkali and is also partly responsible for the fermenting power. W. McC.

**Re-phosphorylation in presence of cozymase.** H. VON EULER, R. VESTIN, and H. HEIWINKEL (Svensk Kem. Tidskr., 1936, 48, 176—183).—In the system, dialysed and aged muscle extract (rabbit)-Mg-phosphocreatine (I), a pyrophosphate (II) fraction is formed by use of (I) in presence of a sufficient amount of a cozymase prep. (III). This action is observed with all samples of (III), independently of method of prep. and degree of purity with the exception of those purified by pptn. with  $\text{EtOAc}$  from  $\text{MeOH-HCl}$ . Products isolated as Ag salts from (III) inactivated by heating with alkali are capable of forming (II). Apparently only 20—25% of (III) is utilised in production of (II). Yields are not increased by increase in temp. or concn. of (I) or (III) or by diminishing the acidity of the solution. Re-esterification takes place rapidly. The (II) produced is freed from a large excess of (I) and (III) by pptn. with metals as used in the isolation of adenosine

triphosphate (IV). It is not formed by the addition of the  $\text{P}_2\text{O}_7$  group to the cozymase mol.; possibly it contains (IV). The substance which acts as substrate in the formation of (II) is probably not identical with cozymase. H. W.

**Cozymase pyrophosphate.** O. MEYERHOF and W. KIESSLING (Naturwiss., 1936, 24, 557—558; cf. this vol., 1026).—Cozymase pyrophosphate (I) has been prepared in purer form; there are 8 N in the mol. to 4 P and 25 C. (I) is not deaminated by inactivated muscle extract. Fermentation by washed, dried yeast is activated more by (I) than by the same amount of cozymase. E. A. H. R.

**Characterisation of sugarphosphoric acids and constitution of the pentosephosphoric acid from cozymase.**—See this vol., 1364.

**Glyoxalase and its co-enzyme. III. Mechanism of the action of glutathione as co-enzyme.** S. YAMAZOYE (J. Biochem. Japan, 1936, 23, 319—334; cf. this vol., 895).—Before conversion into lactic acid (I) and in presence of glyoxalase,  $\text{AcCHO}$  combines (1:1) with glutathione (II). The compound  $\text{AcCHO-(II)}$  (isolated as a crude prep., stable to I) is stable in acid solution, decomp. in neutral or, more rapidly, alkaline media to (I)+(II), a reaction catalysed by glyoxalase. In absence of glyoxalase,  $\text{AcCHO}$  and (II) form a labile complex, readily hydrolysed in neutral or alkaline media to  $\text{AcCHO}$  and (II) [(I) is not formed] and decomposed by I. F. O. H.

**Optical properties of fermentation lactic acids. IV. New enzyme racemase which reveals racemisation of lactic acids.** H. KATAGIRI and K. KITAHARA (J. Agric. Chem. Soc. Japan, 1936, 12, 844—852).—With *Lactobacillus plantarum* and *L. pentoceticus* (dl-formers) in a medium containing PhMe and Ca lactate, the velocity of racemisation was high and identical for both forms of the acid. Racemisation of d- or l-lactic acid or selective decomp. of the r-acid was never observed with *L. Saké* (d-former) and *Leuconostoc mesenteroides* (l-former), even in their resting state. The activity of racemase is only slightly affected by PhMe, but it is sensitive to high temp. (inactivated at  $80^\circ$ ). J. N. A.

**Substance controlling hydrolysing and synthesising actions of lipase. I.** R. ITOH (J. Biochem. Japan, 1936, 23, 299—304).—A detailed account of work already noted (this vol., 895). F. O. H.

**Influence of monochromatic light on action of the fat-splitting enzyme in yeast.** R. MURAKAMI (J. Agric. Chem. Soc. Japan, 1936, 12, 709—713).—The rate of hydrolysis of castor oil by the enzyme from yeast is increased in monochromatic light, the effect increasing with  $\lambda$ . The rate of hydrolysis is inversely  $\propto$  light intensity. J. N. A.

**Absolute activity of choline esterase.** L. H. EASSON and E. STEDMAN (Proc. Roy. Soc., 1936, B, 121, 142—164).—The relative rates at which choline esterase (I) hydrolyses choline esters have been compared with the rates for the non-enzymic hydrolysis. This latter rate approx.  $\propto [\text{OH}^-]$  and decreases with increase in the size of the aliphatic acyl group. The rate of enzymic hydrolysis, with n-acids, in-

creases with the size of the acyl group, but the introduction of a side-chain diminishes the rate. The influence of  $p_H$  on (I) depends on the substrate. For most esters the  $p_H$  optimum is  $>8$ . Within the range  $p_H$  6.8–8.0 the hydrolysis of benzoylcholine is uninfluenced by  $p_H$ . The inhibitory action of miotine (II) on (I) is const. for the different substrates. (II) is unstable in aq. solution. Prostigmine is stable, and its inhibitory action is used to determine the abs. rate of activity of (I). Under nearly optimal conditions one active centre of (I) hydrolyses 3500 mols. of butyrylcholine and 1490 of acetylcholine per sec. The following  $\beta$ -bromoethyl esters were prepared: *formate*, b.p. 147–148°; *propionate*, b.p. 170–175° (slight decomp.), 73–74°/16 mm.; *n*-, b.p. 82.5°/11 mm., and *iso-butyrate*, b.p. 79°/11 mm. The  $\beta$ -bromoethyl esters with a slight excess of  $NMe_3$  gave *formyl*-, m.p. 142°, *propionyl*-, m.p. 146°, *n-butyryl*-, m.p. 100–101°, and *isobutyryl*-, m.p. 127°, *-choline bromide*. E. A. H. R.

**Optical specificity and activation of arginase.** S. EDLBACHER and A. ZELLER (Z. physiol. Chem., 1936, 242, 253–260).—Arginase (I) in conens. usually employed hydrolyses *d*-arginine (II) but not *l*-arginine (III) but when the conen. is greatly multiplied (e.g., 1000-fold) (III) also is quantitatively converted into urea and ornithine. The (I) of pigeon's muscle and kidney and hen's kidney is activated by  $Mn^{++}$ , the action on (II) but not that on (III) being affected.  $NH_2$ -acids (ornithine  $>$  lysine  $>$  glycine  $>$  alanine) check the action of (I) on (II) and (III). W. McC.

**Proteolytic enzymes of sprouted wheat.** II. J. D. MOUNFIELD (Biochem. J., 1936, 30, 1778–1786; cf. this vol., 637).—In germinating wheat seeds proteinase (I) activity increases tenfold in 7 days at 18° after a lag of 2 days. When the seeds are stored in the dark at 18° power to develop (I) activity on germination steadily decreases, the decrease amounting to about 67% in 2 years. In aq. solution all dipeptidase (II) activity is lost in 5 days at 18° but in 45% aq. glycerol (III) the original level of activity is maintained for 21 days. (I) is stable at  $p_H$  4 and 6 but is destroyed at  $p_H$  8 in  $<3$  days at 18° and (II) is fairly stable at  $p_H$  6 and 8 but is destroyed at once at  $p_H$  4. (III) probably acts by maintaining the original  $p_H$  of 6; in aq. extracts the  $p_H$  falls to 4–5 in 1–2 days. NaCN activates (I) and (II), the increase in activity being about 60% for (I) with edestin as substrate (max. requirement of NaCN 0.001*M*), the optimal  $p_H$  being shifted from 4.1 to 4.8. (II) is less affected but the optimal  $p_H$  is shifted also from 7.3 to 7.8 with leucylglycine as substrate and from 7.9 to 8.1 with glycylglycine. W. McC.

**Proteolytic enzymes in the tape worm.** I. A. SMORODINCEV and K. V. BEBESCHIN (Bull. Soc. Chim. biol., 1936, 18, 1097–1105).—Glycerol extracts of *Taeniarhynchus saginatus* and *Taenia solium* contain pepsin, trypsin, and cathepsin, the tryptic action of extracts of the former being  $>$ , and the peptic action  $<$ , that of the latter species. No activation of the cathepsin occurred with  $H_2S$ .

A. L.

**Selective action of gentian-violet on enzymes.** A. Y. WELLS and N. P. SHERWOOD (J. Infect. Dis., 1934, 55, 356–359).—Gelatinases from Gram-positive bacteria were more easily inhibited by gentian-violet (1:400) in acid media than were those from Gram-negative bacteria. Enzymes from the latter liquefied the larger amounts of gelatin. All the enzymes were more active in alkaline media. CH. ABS. (p)

**General nature of catheptic enzymes.** M. BERGMANN and J. S. FRUTON (Science, 1936, 84, 89–90).—A discussion and interpretation of the dual enzyme system of catheptic enzymes. L. S. T.

**Conditions for the action of cathepsin in the tissues of the regenerating organs of amphibia.** V. N. ORECHOVITSCH (Biochem. Z., 1936, 286, 285–289).— $H_2S$  does not activate the cathepsin (I) of regenerating tissues. Cysteine (II) activates the (I) of normal tissues strongly and, to a smaller extent, that of regenerating tissue. With max. activation, the hydrolysis of gelatin by extracts of regenerating tissues is  $>$  that by extracts of normal tissue. The intensity of autolysis of normal tissues with max. (II) activation is  $<$  that of the non-activated autolysis of regenerating tissue.

P. W. C.

**Determination of peptic activity.** III. H. ESCHENBRENNER (Pharm. Ztg., 1936, 81, 967–969; cf. this vol., 520).—The possible influence of the hydrolytic products on the course of proteolysis by pepsin is discussed. Evidence of inhibition could not be obtained from the effect of dialysis or addition of peptones on peptic digestion. Polarographic examination indicates that peptic hydrolysis produces only slight changes in the protein substrate. F. O. H.

**Activation of pancreatic trypsin.** F. MOCOROA (Anal. Fis. Quím., 1934, 32, 748–756).—From a study of the rates of activation it is concluded that active trypsin (I) is formed from trypsin and kinase, and that its formation is influenced by their conen. and by temp. (I) combines with prokinase to give a kinase. F. R. G.

**Specificity of urease.** R. BONNET and R. RAZAFIMAHERY (Enzymologia, 1936, 1, 55–59).—Heated and unheated urease show no difference in hydrolysing various substituted ureas, amides, and cyanates. Urease is very sp. E. D. Y.

**Inhibitory effect of phloridzin and phloretin on kidney phosphatase.** H. KALCKAR (Nature, 1936, 138, 289).—The inhibitory effect of phloretin on the action of kidney phosphatase is approx. 3 to 4 times that of phloridzin. L. S. T.

**Metabolism of the human placenta.** O. BUSSE (Z. physiol. Chem., 1936, 242, 271–279).—The placenta contains a phosphatase (I) the activity of which depends on the substrate conen. (max. with 0.15*M*-glycerophosphate at  $p_H$  9). (I) is slightly activated by  $Mg^{++}$ , strongly inhibited by cysteine, unaffected by NaF, EtOH, and  $COMe_2$ , and partly purified by fractional pptn. with EtOH. The (I) content of the ripe placenta is  $>$  that of the unripe and that of the liver, kidney, and small intestine. The zymohexase content of the placenta is only a fraction of

that of muscle. No phosphorylation of inorg. P occurs in the placenta. W. McC.

**Alcoholic fermentation in the intact enzyme system of the yeast cell and in the disorganised zymase system.** II. R. NILSSON and F. ALM (Biochem. Z., 1936, 286, 373—391).—The fermentation by preps. of intact dry yeast (cf. this vol., 1299) is compared with those by apozymase (I), autolysed dry yeast, and maceration extract and the effect of autolysis and PhMe examined. Yeast which is allowed to autolyse during slow drying loses the power to ferment sugar completely and gives the normal linear curve whilst addition of  $\text{PO}_4'''$  causes a sharp break in the curve. Maceration juice gives larger deviations and with amounts of  $\text{PO}_4'''$  below theoretical gives 2 such breaks, the first conditioned by the  $\text{PO}_4'''$  and the second occurring when one half of the sugar is fermented. (I) + purified co-enzyme gives the normal curve but if the (I) is first dried in air, only half of the sugar is fermented at the normal rate. The changes in the enzyme system are discussed and correlated with similar changes in fermentation with dry yeast at  $40^\circ$ . P. W. C.

**Polysaccharides fermented by yeast in wheaten flour.** R. GUILLEMET and C. SCHELL (Bull. Soc. Chim. biol., 1936, 18, 1132—1146).—Fermentation of raffinose by baker's yeast in the presence of aq. yeast extract takes place completely, and that of gentianose and stachyose corresponds with 66 and 50% respectively of the carbohydrate added. Fermentation of levosin is, however, much less. Baking flour contains about 0.1% of hexoses, 0.2—0.7% of sucrose, and 1% of a mixture of polysaccharides amongst which is levosin. A. L.

**Effect of composition of medium on growth of yeast in presence of bios preparations.** I. Effect of magnesium salts. E. I. FULMER, L. A. UNDERKOFER, and J. B. LESH (J. Amer. Chem. Soc., 1936, 58, 1356—1358).—Growth of a strain of *Saccharomyces cerevisiae* on a  $\text{NH}_4\text{Cl}$ — $\text{K}_2\text{HPO}_4$ —sucrose medium with added bios II (essential) is markedly increased by small concns. of  $\text{MgSO}_4$  [or  $\text{MgCl}_2$  or  $\text{Mg}(\text{NO}_3)_2$  with  $\text{K}_2\text{SO}_4$  or  $(\text{NH}_4)_2\text{SO}_4$ ].  $\text{K}_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{SO}_4$  show some activity but  $\text{MgCl}_2$  and  $\text{Mg}(\text{NO}_3)_2$  do not. H. B.

**Action of small quantities of copper on alcoholic fermentation by yeast. Application to wine-making.** R. GUILLEMET (Bull. Soc. Chim. biol., 1936, 18, 1125—1131).—The fermentation of aq. glucose by yeast ceases when the yeast has taken up 2.3—2.5 mg. of Cu per g. (dry wt.). The retarding effect of Cu on the fermentation of wine musts, however, takes place only when 500 mg. of Cu per litre are present. This amount is  $\gg$  that present after fungicidal treatment of the grapes. A. L.

**Comparative action of sodium arsenate, sodium arsenite, and arsenic-protein preparations on respiration and glycolysis of *Saccharomyces cerevisiae*.** P. MASCHERPA (Boll. Soc. ital. Biol. sperim., 1936, 11, 253—255).—The toxic effect (depression of respiration and glycolysis) gives the order As-gelatin  $>$   $\text{Na}_3\text{AsO}_3 >$   $\text{Na}_3\text{AsO}_4$ . F. O. H.

4 z

**Effect of radium rays on fermentation micro-organisms. Formation of constant variants of yeasts under influence of hokutolit rays.** R. NAKAZAWA and M. SIMO (J. Agric. Chem. Soc. Japan, 1936, 12, 699—708).—Morphologically and physiologically distinct variants are produced when yeasts are exposed to hokutolit rays. J. N. A.

**Mitogenetic effect on yeast of oligodynamic radiations from metals.** M. B. MACDONALD (Iowa State Coll. J. Sci., 1935, 9, 587—595).—Yeast cells multiplied much more rapidly in tubes placed on sheet brass, Fe, Pb, Al, or Ag than on cardboard. In Vitreosil tubes growth was retarded by the metals, probably through excessive transmission of radiations. Protection of the metal surfaces from contact with the atm. diminished their action. Exposure of the medium to metal before inoculation also increased multiplication and the beneficial effect thus obtained was not affected by boiling the treated medium before inoculation. CH. ABS. (p)

**Carbohydrates of yeast.** K. SILBEREISEN (Woch. Brau., 1936, 53, 317—321, 330—331).—A lecture.

**Permeability of yeast cell-membrane.**—See B., 1936, 1013.

**Micro-organisms of sugar cane juice.** R. NAKAZAWA, Y. TAKEDA, and K. SUEMATU (J. Agric. Chem. Soc. Japan, 1936, 12, 749—762).—1 c.c. of juice contained  $10^4$  to  $10^5$  micro-organisms consisting of *saccharomyces*, *torula*, *monilia*, and *bacteriu* (mainly *Leuconostoc*). All are able to invert sugar. The juice is well suited to the growth of the organisms, which can be altered by change of  $p_H$ , rise of temp., or addition of bleaching powder. J. N. A.

**Grouping of *Monilia* by fermentation and precipitin reactions.** J. H. LAMB and M. L. LAMB (J. Infect. Dis., 1935, 56, 8—20).—*Monilia* species are divided into 3 groups on the basis of sugar fermentation tests and precipitin reactions.

CH. ABS. (p)

**Properties of *Aspergillus* species.** II. Y. TAKEDA and O. TAKEUCHI (J. Agric. Chem. Soc. Japan, 1936, 12, 853—870).—The optimum temp. for growth and for conidia formation, the permanence and colour of conidia, colour of perithecia, optimum  $p_H$  for growth, killing temp., and fermentative or non-fermentative activity for all kinds of carbohydrates are determined for 89 known strains of *Aspergillus* grown on Pfeffer's medium containing 0.5% of oryzanin. J. N. A.

**Utilisation of galactose by *Aspergillus niger* and *Penicillium glaucum*.** W. H. HERR (Plant Physiol., 1936, 11, 81—99).—Galactose (I) is a poor source of C for these moulds and when used alone retards spore germination and mycelial development. When mixed with glucose, fructose, or mannose, (I) improves growth. Addition of lactose to a sucrose culture medium has little effect on growth. The acidity of media is not an important factor in growth acceleration. A. G. P.

**Biochemical method for determining parasitism in *Fusarium*.** T. FEDOTOVA (Plant Protection U.S.S.R., 1935, No. 1, 115—118).—Highly parasitic,

weakly parasitic, and saprophytic species contained  $\text{NH}_2\text{-N}$  3—5, 11—19, 19—27, and  $\text{NH}_2\text{-N}$  6—8, 9—28, 35—52 mg. per g., respectively.

CH. ABS. (p)

**Nitrogenous metabolism of a micro-organism.** W. H. SCHOFFER (Compt. rend., 1930, 203, 201—203).—Cultures of *Phycomyces* on a medium containing 8% of glucose and 0.1% of asparagine show a max. yield of the mould for a definite concn. of vitamin- $B_1$ . Many other N sources give similar results. The N content of the mould falls to a min. as the yield reaches a max. although all the available N is not utilised. Atm.  $\text{N}_2$  plays no part in the process.

**Production of sclerotia by *Rhizoctonia solani*, Kuhn, in pure culture.** L. E. TYNER and G. B. SANFORD (Sci. Agric., 1935, 16, 197—207).—No sclerotia were produced in P- or N-free media. Optimum and min. concns. were 31 and 7.5 for P and 560 and 55 p.p.m. for N. Sclerotia appeared with almost equal frequency over a wide range of [K] > 2 p.p.m. Sclerotia formation was restricted with < 20 p.p.m. of Mg in the nutrient. Omission of Ca did not affect development of either sclerotia or mycelium. Sclerotia were produced readily in media of  $p_{\text{H}}$  3—9 (optimum 5.5) and were most favoured by temp. of 18—21° and R.H. 60%. Radiations from pitchblende had a stimulatory effect. A. G. P.

**Effects of hypertonic media on the contractile vacuoles of protozoa.** J. A. KITCHING (Nature, 1936, 138, 287).—A discussion. L. S. T.

**Chemotherapy of animals infected with trypanosomes by inhibiting carbohydrate metabolism of the parasites with halogenoacetic acids.** N. VON JANCsó and H. VON JANCsó (Biochem. Z., 1936, 286, 392—395).—Trypanosome infection of mice was removed by intraperitoneal administration of  $\text{CH}_2\text{Br}\cdot\text{CO}_2\text{H}$  and  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$ . P. W. C.

**Physiology of respiration of bacteria. II. Intracellular indophenol reaction.** S. YAMAGUCHI (Acta Phytochim. Japan, 1935, 8, 263—283).—The indophenol test was positive with 9 among 24 species examined, and was inhibited by  $\text{CN}^-$ . With certain species the  $\text{O}_2$  absorption was lowered by  $\text{CO}$ .

CH. ABS. (p)

**Bacterial growth and hydrogen-ion concentration. I. In bouillon. II. In peptone water.** A. UCHIDA (Japan J. Mikrobiol. Path., 1935, 29, 825—868).—[ $\text{H}^+$ ] decreased at first and increased later (more rapidly in bouillon).

CH. ABS. (p)

**Content of hydrolases in some species of bacteria.** G. VERCELLANA (Boll. Soc. ital. Biol. sperim., 1936, 11, 329—330).—Trypsin, cathepsin, amylase, and lipase were not found in *B. melitense*, *B. paramelitense*, *B. abortus*, *B. para-abortus*, *B. pyocyaneum*, *Vibrio cholerae*, *Staphylococcus pyogenes aureus*, or *Streptococcus pyogenes*. F. O. H.

**Reactions of organisms on arbutin agar.** A. CASTELLANI and M. DOUGLAS (J. Trop. Med. Hyg., 1935, 38, 197—201).—Certain organisms produce brown to black colorations. The reaction does not correspond with the fermentation of arbutin in peptone.

CH. ABS. (p)

**Acetic acid bacteria from Formosa. X. Systematic investigations.** S. TANAKA (J. Agric. Chem. Soc. Japan, 1936, 12, 726—744).—105 strains are divided into 4 groups, according to the amounts of  $\text{AcOH}$  and gluconic acid produced on an  $\text{EtOH}$ -glucose medium. J. N. A.

**Mechanism of biological fixation of nitrogen. III. Economy of carbon during fixation by *Azotobacter chroococcum*, Beij.** T. R. BHASKARAN. IV. Fixation by the mixed microflora of soil in presence of acid products of anaerobic decomposition of carbohydrates. T. R. BHASKARAN and V. SUBRAHMANYAN (Proc. Indian Acad. Sci., 1936, 4, B, 67—74, 163—170; cf. this vol., 113).—III. The decomp. products of glucose play no part in the fixation of N by *A. chroococcum*, the mechanism of which differs from that by mixed soil flora. During the early stages of sugar decomp. the proportion of C fixed in the slime and bacterial cells is relatively > that of N. Later the ratio is adjusted to the initial level. Growth of the organism and N fixation are closely correlated.

IV. The efficiency of the fixation of N by a mixed flora was improved by addition of the mixture of org. acids etc. obtained by the anaerobic fermentation of sugar. The ratio of C consumed to N fixed is examined under various cultural conditions.

A. G. P.

**Utilisation of salicylic acid as an energy-producing food by *Azotobacter* in soil.** G. GUITTONNEAU and R. CHEVALIER (Compt. rend., 1936, 203, 211—213; cf. A., 1932, 437).—*Azotobacter* from gardens and fields when grown on  $\text{SiO}_2$  gel or the original soil containing Na salicylate (I) utilises (I) better if the soil fertility is high. A pure culture destroys (I), increases the  $p_{\text{H}}$  of the medium, and fixes N during some days, indicating that no subsidiary bacteria are necessary to enable *Azotobacter* to utilise (I).

J. L. D.

**Alcohol- and carbohydrate-oxidising bacteria isolated from fruits : new classification of oxidising bacteria. III.** T. ASAI (J. Agric. Chem. Soc. Japan, 1935, 11, 331—340, 377—390, 499—513, 610—620, 674—708; cf. this vol., 113).—Decomp. of sugars and alcohols by numerous species of bacteria is examined. Species growing at higher temp. oxidise glucose (I) to gluconic or glycuronic acid (II) and  $\text{AcOH}$  to  $\text{CO}_2$ , but do not oxidise mannitol (III) or glycerol (IV). Those growing at lower temp. oxidise (I) to (II) or 5-ketogluconic acid, (III) to fructose (V), (V) to kojic acid, and (IV) to  $\text{CO}(\text{CH}_2\cdot\text{OH})_2$ . They do not oxidise  $\text{AcOH}$ . The extent of these reactions forms the basis of a classification of species.

CH. ABS. (p)

**Thermophilic and anaerobic nature of *Lactobacillus bulgaricus*.** J. M. SHERMAN and H. M. HODGE (Science, 1936, 84, 208—209).—Freshly isolated cultures can grow at 60° and vigorously at 55°.

L. S. T.

**Quantum relationship of the light-emitting process of luminous bacteria.** K. L. VAN SCHOUWENBURG and J. G. EYMERS (Nature, 1936, 138, 245).—One part of the  $\text{O}_2$  consumption of *Photobacterium phosphoreum* is completely inhibited by

approx. 0.001M-KCN, and the other decreases slowly with increasing [KCN] and  $\propto$  light intensity. 19% of the total  $O_2$  is consumed in the light-emitting process and at 16°, 500 mols. of  $O_2$  are consumed per quantum of light emitted. The efficiency of the light-emitting process depends on various unknown factors.

L. S. T.

**Preparation of specific bacterial carbohydrate substances by electrolysis.** A. C. H. YEN and T. J. KUROCHKIN (J. Infect. Dis., 1935, 56, 238—249).—Passage of a strong electric current through saline suspensions of the organisms causes clarification. Dialysis of the cleared solution removes protein matter, and  $H_2O$ -sol. polysaccharides are pptd. from the resulting liquid by EtOH.

CH. ABS. (p)

**Comparative behaviour of endotoxins and exotoxins towards trichloroacetic acid.** A. BORVIN (Compt. rend., 1936, 203, 284—286).—The anatoxin of *B. diphtheriae* is pptd. by  $CCl_3 \cdot CO_2H$  at  $p_H$  4, and can be redissolved in  $PO_4'''$  buffer of  $p_H$  8. In this way it is possible to concentrate and purify the anatoxins. The purified material contains mineral matter 0.5, N 15.1, and P 0.1%; it yields no sugar, purine, or fatty acid on hydrolysis. The endotoxin, which is a carbohydrate-lipin complex and is responsible for the specificity of the type, is sol. in  $H_2O$  at  $p_H$  4.

P. G. M.

**Metabolism of *C. diphtheriae*.** I. A. TASMAN and A. C. BRANDWIJK (Biochem. J., 1936, 30, 1756—1767).—*Diphtheria* bacteria in a simple culture medium assimilate glucose (I) in concns.  $\geq$  0.2% without detriment to toxin production. When the concn. is 0.5% all (I) is (more slowly) decomposed but toxin production is stopped because of the large amount of acid produced. Much greater concns. of maltose (II) are tolerated, apparently because the velocity of decomp. of (I) by the bacteria is 6 times that of hydrolysis of (II) to (I). During decomp. of sugar the  $p_H$  falls until (I) has disappeared and then rises, probably because the acids initially produced from (I) are oxidised to  $H_2O$  and  $CO_2$  which converts alkali originally present into  $CO_3''$  and  $HCO_3'$ . Production of toxin begins when (I) has practically disappeared, continues for a time at approx. const. velocity, and then ceases abruptly.

W. McC.

**Inhibitive effect of vitamin-C on toxin production by *C. diphtheriae*.** I. J. KLIGLER (Nature, 1936, 138, 291).—Vitamin-C added in small amounts to a suitable medium inhibits toxin production.

L. S. T.

**Diphtheria toxin produced on a semi-synthetic medium.** K. ANDO and T. KOMIYAMA (J. Immunol., 1935, 28, 345—352).—On a mineral salt-AcOH-maltose-Difco-proteose-peptone medium at  $p_H$  8.0, *C. diphtheriae* produces a toxin as potent as that obtained in ordinary infusion bouillon.

CH. ABS. (p)

***Cl. welchii*, Type C, Wilsdon (*B. patudis*, McEwen), isolated from sheep in N. Wales.** R. F. MONTGOMERIE and W. T. ROWLANDS (Vet. Rec., 1936, 48, 829—832).—In cases of sheep "strike," a toxin typical of *Cl. welchii* was isolated from blood and other body-fluids.

A. G. P.

**Differential character of *Clostridium welchii*, type D.** T. J. BOSWORTH and R. E. GLOVER (Proc. Roy. Soc. Med., 1935, 28, 1004—1006).—The toxin prepared in saline becomes much more toxic when mixed with a normal intestinal filtrate. The activating factor is destroyed at 70°. The same amount of antitoxin is required to neutralise the treated and the untreated toxin.

CH. ABS. (p)

**Antigenic relation between *Proteus vulgaris* X-19 and typhus *Rickettsia*.** III. Antigenic composition of extracts of *P. vulgaris* X-19. M. R. CASTANEDA (J. Exp. Med., 1935, 62, 289—296).—Two polysaccharides, 1 and 4% N, respectively, are pptd. from extracts by EtOH. Both give a negative biuret and a positive Molisch reaction. One, the common antigenic factor in *P. vulgaris* X-19 and typhus *Rickettsia*, is stable to hot alkali, the other is quickly destroyed.

CH. ABS. (p)

**Oxidation-reduction potentials in *Salmonella* cultures.** I. Development of potential levels characteristic of species. W. BURROWS and E. O. JORDAN (J. Infect. Dis., 1934, 56, 255—263).—The potentials of cultures of individual strains differed only within narrow limits. Those of different species diverged considerably. Species-differences may be due to differences in bacterial substances synthesised.

CH. ABS. (p)

**Antigenic structure of the variants of *Staphylococcus aureus*.** I. Carbohydrates of the rough and smooth forms. R. E. HOFFSTADT and W. M. CLARK (J. Infect. Dis., 1935, 56, 250—254).—Type-sp. carbohydrates isolated from the two forms differed antigenically and in the manner in which they separated from the proteins of the respective organisms. That from the smooth type was more sol. in hot  $H_2O$ , and contained less N, than that from the rough type, from which it also differed in being pptd. by  $Ba(OH)_2$ .

CH. ABS. (p)

**Ingestion of *Staphylococcus* exotoxin by human volunteers with special reference to staphylococcic food poisoning.** C. E. DOLMAN (J. Infect. Dis., 1934, 55, 172—183).—Gastric disturbance followed the ingestion in some cases only. A staphylococcus metabolite rather than the exotoxin was probably the causal agent.

CH. ABS. (p)

**Influence of  $p_H$  on dissociation of *B. Friedlander* and *M. tuberculosis*.** W. STEENKEN (J. Infect. Dis., 1935, 56, 273—276).—The effects of the reaction of various media on attenuation are examined.

CH. ABS. (p)

**Effect of formaldehyde on growth of tubercle bacilli.** R. D. HERROLD (J. Lab. Clin. Med., 1935, 20, 1165—1167).—Tubercle bacilli are more susceptible to  $CH_2O$  than are other common organisms present in sputum.

CH. ABS. (p)

**Attenuated (R.I.) tubercle bacilli recovered from silicotic and normal guinea-pigs.** G. R. DOWD (Amer. Rev. Tuberc., 1935, 32, 62—72).

CH. ABS. (p)

**Ultra-violet absorption of phthiocol, a pigment of the human tubercle bacillus.** M. O'L. CROWE (J. Biol. Chem., 1936, 115, 479—484).—The absorption spectrum of synthetic phthiocol (A., 1934, 77)

in 95% EtOH (max. at 385, 334, 278, and 250 m $\mu$ ) is compared with those of other 1:4-naphthaquinones. F. A. A.

**Concentration and partial purification of bacteriophage.** J. H. NORTHROP (Science, 1936, 84, 90—91).—A protein prep. possessing the properties of bacteriophage has been isolated from lysed staphylococcus cultures. Method and properties are described. L. S. T.

**Feulgen reaction of the bacteriophage substance.** M. SCHLESINGER (Nature, 1936, 138, 508—509).—The particles of *coli* bacteriophage previously prepared (A., 1934, 1407) are extensively stained by Feulgen's reagent. L. S. T.

**Reactivation of thermally inactivated bacteriophage.** A. P. KRUEGER and J. H. MUNDELL (Proc. Soc. Exp. Biol. Med., 1936, 34, 410—413).—Bacteriophage inactivated by heating for 20 min. at 54° in a phthalate buffer mixture at  $p_H$  5.75 is partly reactivated when kept on ice at  $p_H$  8.1. W. O. K.

**Selective action of dyes and of other disinfectants on bacteriophage.** A. Y. WELLS and N. P. SHERWOOD (J. Infect. Dis., 1934, 55, 195—198).—The phagistatic action of gentian-violet, crystal-violet, PhOH, and NaOH is examined. In general, phages acting on Gram-negative bacteria are more resistant to inhibitory substances than are those which act on Gram-positive organisms. CH. ABS. (p)

**Immunological and chemical investigations of vaccine virus. II. Analysis of elementary bodies of vaccinia.** T. P. HUGHES, R. F. PARKER, and T. M. RIVERS (J. Exp. Med., 1935, 62, 349—352).—Washed elementary bodies contain protein 83.1, fat 8.5, ash 0.7, residual H<sub>2</sub>O 5.6%. The 2% of undetermined matter includes a trace of carbohydrate. CH. ABS. (p)

**Resistance of the virus of infectious laryngo-tracheitis to certain chemical and physical factors.** O. W. SCHALM and J. R. BEACH (J. Infect. Dis., 1935, 56, 210—223).—Effects of temp., exposure to sunlight,  $p_H$ , desiccation, and treatment with PhOH, cresol, and NaOH are examined. CH. ABS. (p)

**Attenuation of avian plague virus by X-rays.** B. S. LEVIN and I. LOMINSKI (Compt. rend., 1936, 203, 287—288).—A dose of X-rays of 2500—3000 kiloroentgen is required to attenuate plague virus as tested in cockerels. This dose is > that required to kill bacteria (300 kiloroentgen). X-Rays may therefore be used for purification of an ultravirus. P. G. M.

**Thermostable activators of bacterial growth from cryptogams.** A. SARTORY, R. SARTORY, J. MEYER, and M. J. MERGLEN (Compt. rend., 1936, 203, 280—282).—H<sub>2</sub>O-sol. bacterial activators in culture filtrates of *Aspergillus fumigatus*, *Schizosaccharomyces hominis*, *Mucor nigricans*, and *M. plumbeus* manifest themselves only on heating to <80°. They resist prolonged heating at 120°. The two *Mucor* strains give the best growth with all the cocci used. The growth of *B. diphtheriae* is only slightly affected by any of the filtrates, and that of *B. subtilis* not at all. P. G. M.

**Different effects of some disinfectants on bacterial growth.** K. DIERNHOFFER (Milch. Forsch., 1936, 18, 83—86).—On growing a mixture of types of bacteria isolated from cow dung in lactose broth containing various low concns. of KCN, OH·C<sub>6</sub>H<sub>3</sub>(NO<sub>2</sub>)<sub>2</sub>, *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·OH, and theophylline-Na salicylate, a differentiation in the growth of streptococci and Gram-negative bacteria was obtained. 0.05—0.10% of nitrophenols did not affect the growth of streptococci but KCN favoured the growth of Gram-negative organisms. W. L. D.

**Antiseptic and bactericidal action of urea.** J. H. FOULGER and L. FOSHAY (J. Lab. Clin. Med., 1935, 20, 1113—1117).—Many bacteria lose viability in 2 hr. in media half-saturated with urea. Staphylococci have a high resistance. Dry urea may be applied directly to suppurating wounds etc. CH. ABS. (p)

**Germicidal properties of the soil nema, *Rhabditis pellio*.** Schneider. C. MORIYA (Proc. Imp. Acad. Tokyo, 1936, 12, 195—197).—Various pathogenic organisms are destroyed by *R. pellio*. A. G. P.

**Culture media for non-acid products.** E. J. CAMERON (J. Assoc. Off. Agric. Chem., 1936, 19, 433—438).—Five media are described and recommended for the detection of all organisms commonly found in such products. E. C. S.

**Culture media for acid products.** B. A. LINDEN (J. Assoc. Off. Agric. Chem., 1936, 19, 440—445).—Five media are described and recommended for the detection of bacteria and one for the detection of yeasts and moulds. E. C. S.

**Meker burner with auxiliary flame for bacteriological use.** M. E. HIGHLANDS and P. K. BATES (Amer. J. Publ. Health, 1936, 26, 928). C. J.

**Use of micro-organisms in sugar analysis.**—See this vol., 1363.

**Effect of prolonged administration of hyperglycaemia-producing hormones.** F. SERIO (Boll. Soc. ital. Biol. sperim., 1936, 11, 270—271).—Prolonged administration of adrenaline, thyroxine, or pituitary preps. to dogs produces a hypoglycaemia and not a condition simulating diabetes. The mechanism of this phenomenon is discussed. F. O. H.

**Adrenal cortex and cholesterol metabolism.** S. THADDEA and W. FASSHAUER (Arch. exp. Path. Pharm., 1936, 182, 477—498).—Intravenous injection of adrenal cortex preps. (I) into dogs decreases the total cholesterol (II) content of the serum, the diminution being mainly of cholesteryl ester (III). The effect does not occur after damage of the reticulo-endothelial system. Bilateral extirpation of the adrenal cortex in cats increases serum-(II) [especially the (III) fraction] and decreases liver- and muscle-(II); subsequent treatment with (I) produces a return to normal vals. and also corrects the absence of hypercholesterolaemia (due to disturbance of fat-absorption) following oral administration of (II). Increased serum-(II) and -(III) occur in Addison's disease. The adrenal cortex probably has a fixative action on (II). F. O. H.

**Adrenal cortex and endogenous carbohydrate formation.** G. EVANS (Amer. J. Physiol., 1936, 114, 297—308; cf. A., 1935, 777).—The increase of glycogen (I) in fasting rats exposed to reduced pressure is prevented by hypophysectomy. A parallel increase in N excretion and R.Q. and a fall in O<sub>2</sub> consumption are observed in intact rats. Adrenalectomy abolishes the increase in N excretion; it also reduces excretion of sugar and N in phloridzinised rats. Adreno-medullectomised rats respond to low O<sub>2</sub> tension and phloridzin as do intact rats. The cortical extract of Swingle and Pfiffner does not alter sugar and N excretion of adrenalectomised phloridzinised rats, nor raise (I) in rats exposed to reduced pressure. Ketosis in phloridzinised rats and rats exposed to reduced pressure is diminished by adrenalectomy. It is concluded that the cortex is concerned with the conversion of protein into carbohydrate.

R. N. C.

**Constituents of the adrenal gland. V. Chemical identification of the androstane skeleton.**—See this vol., 1382.

**Constituents of the adrenal gland. VI. Methods of separation and isolation of the substances Fa, H, and J.**—See this vol., 1382.

**Carbohydrate and electrolyte changes in the opossum and marmot following adrenalectomy.** H. SILVETTE and S. W. BRITTON (Amer. J. Physiol., 1936, 115, 618—626).—Serum- and muscle-Na and -Cl are increased and muscle-H<sub>2</sub>O decreased. Na<sup>+</sup> and Cl<sup>-</sup> excretion in the urine is < normal. The changes produced in dogs, cats, and rats are strikingly opposite to these. In all species blood-sugar and liver- and muscle-glycogen are decreased. The life-maintaining cortical hormone affects NaCl balance only indirectly, being directly concerned in regulation of carbohydrate metabolism.

R. N. C.

**Changes in the rat incisor following bilateral adrenalectomy.** I. SCHOUR and J. M. ROGOFF (Amer. J. Physiol., 1936, 115, 334—344).—Calcification of dentine is disturbed.

R. N. C.

**Increased salt appetite of adrenalectomised rats.** C. P. RICHTER (Amer. J. Physiol., 1936, 115, 155—161).

R. N. C.

**Lactation in adrenalectomised rats.** R. GAUNT and C. E. TOBIN (Amer. J. Physiol., 1936, 115, 588—598).

R. N. C.

**Role of potassium in adrenaline action.** W. J. R. CAMP and J. A. HIGGINS (J. Pharm. Exp. Ther., 1936, 57, 376—387).—K effects all the typical changes in systems which are produced by adrenaline, and the action of K is obtained after decerebration, bilateral adrenalectomy, and injection of atropine and ergotoxine. K is liberated from the heart by vagus stimulation. The adrenals maintain a const. distribution of K.

J. N. A.

**Effect of adrenaline on arterial and venous plasma-sugar and blood flow in dogs and cats.** C. F. CORI, R. E. FISHER, and G. T. CORI (Amer. J. Physiol., 1935, 114, 53—68).—The rate of continuous injection of adrenaline (I) solution necessary to produce hyperglycemia in dogs is > that required for cats. Rates of injection can be found which increase

plasma-sugar (II) without affecting blood-flow. The arterio-venous (II) difference is slightly increased during a period of even (I) hyperglycemia; insulin injected at the conclusion of the (I) injections causes a considerable increase. The increase of (II) in cats is > in dogs for the same rate of injection of (I).

R. N. C.

**Formation of an adrenaline-like substance in autolysing adrenal glands.** A. R. LARRAIN, R. G. ROBERTS, and M. M. KUNDE (Amer. J. Physiol., 1936, 115, 662—664).—Autolysis produces a dialysable pressor substance that resembles adrenaline in its chemical reactions, but is not pptd. by conc. aq. NH<sub>3</sub>. Its formation continues until the gland is almost completely disintegrated; KCN inhibits its formation.

R. N. C.

**So-called virtual adrenaline of the adrenal cortex.** J. DEVINE (Biochem. J., 1936, 30, 1768—1774; cf. Abelous and Argaud, A., 1934, 1038, 1143).—Chemical and physiological assays of extracts of adrenal cortex and medulla give no support to the hypothesis of the existence in the gland of "virtual" adrenaline (I) but the distribution of derivatives of *o*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> in the gland suggests that the cortex may be concerned in the production of (I).

W. McC.

**Adrenaline and urine formation in the dog.** E. F. ADOLPH (Amer. J. Physiol., 1936, 115, 200—209).

R. N. C.

**Changes in the circulatory effect of potassium salts due to adrenaline.** H. A. MCGUIOAN and J. A. HIGGINS (Amer. J. Physiol., 1935, 114, 207—211).—K<sup>+</sup> injected intravenously after adrenaline in the dog is as effective in raising the blood-pressure as when injected intra-arterially; an increase in blood-K<sup>+</sup> is necessary before the action can occur.

R. N. C.

**Regulation of oxygen output by erythrocytes. III. Blood glycolysis, insulin, and adrenaline.** F. HEMMERICH and F. S. TSCHERNJAK (Biochem. Z., 1936, 286, 344—359).—In men and rabbits, insulin (I) accelerates and adrenaline (II) inhibits glycolysis. After administration of (I) or (II), the opposing hormone is mobilised by the organism and secreted into the blood. In man, activation of glycolysis by (I) is > and of longer duration than inhibition by (II). Since increased glycolysis is bound up with increased output of O<sub>2</sub> by the erythrocytes (this vol., 494), (I) and (II) may be regarded as regulators of the blood respiratory function.

P. W. C.

**Enteral absorption of insulin. Protection of insulin against trypsin.** F. LASCH and E. SCHONBRUNNER (Arch. exp. Path. Pharm., 1936, 182, 452—458; cf. this vol., 525).—Certain basic dyes (I) (e.g., malachite-green), but not acid dyes, protect insulin from inactivation *in vitro* by trypsin (II). Pptn. (indicated by an opalescence when protection is max.) of (I) and (II) occurs.

F. O. H.

**Response of the rabbit to insulin.** L. B. DORTT (Amer. J. Physiol., 1936, 114, 538—550).—The % fall in blood-sugar (I)  $\frac{1}{2}$  hr. after administration of a fixed dose of insulin (II) is related to the time of onset

of convulsions; the latter, however, is not related to the initial (I). Animals with great sensitivity to (II) require larger injections of glucose to prevent convulsions. The female is more sensitive to (II) and more const. in its responses than the male.

R. N. C.

**Protamine insulinate.** H. C. HAGEDORN, B. N. JENSEN, N. B. KRARUP, and I. WODSTRUP (J. Amer. Med. Assoc., 1936, 106, 177—180).—Fish sperm protamines combine with insulin (I) to form complexes which have isoelectric points at about  $p_H$  7.3, at which point they are only very slightly sol. in  $H_2O$  but somewhat more sol. in serum. The low solubility in body-fluids results in slow absorption of (I) from subcutaneously administered complexes, with hypoglycaemic action about twice as long as that due to the same dose of ordinary (I). The use of protamine insulinate permits a greater stabilisation of the diabetic blood-sugar level than is possible with ordinary (I) and considerably decreases the risk of hyper- and hypo-glycaemia.

NUTR. ABS. (m)

**Contrary actions of epiphyseal extracts on blood-ketones.** L. CANNARO (Boll. Soc. ital. Biol. sperim., 1936, 11, 273—274).—Aq. and glycerol extracts of fresh pineal gland and  $Et_2O$  extracts of  $COMe_2$ -dried gland contain a thermolabile principle which lowers blood-ketones (I) whilst  $CHCl_3$  extracts of  $COMe_2$ -dried gland contain a thermostable substance which increases (I).

F. O. H.

**Effect of irradiated ergosterol and parathyroid extract on the rate of disappearance of intravenously-injected calcium chloride.** S. FREEMAN (Amer. J. Physiol., 1936, 115, 701—705).—The rate of removal of  $CaCl_2$  in normal dogs is uniform. It is decreased by injection of sufficient parathyroid extract or irradiated ergosterol to produce a fasting hypercalcaemia.

R. N. C.

**Response of thyroid glands of hypophysectomised newts to injections of phyone and their reaction after cessation of treatment.** A. E. ADAMS and F. MARTINDALE (Anat. Rec., 1936, 65, 319—331).

R. N. C.

**Thyroid glands of hypophysectomised newts after treatment with anterior pituitary, thyroid, and iodine.** A. E. ADAMS and B. GRAY (Anat. Rec., 1936, 65, 69—81).—Only the pituitary hormones stimulate the gland.

R. N. C.

**Effects of thyrotropic and adrenotropic principles on hypophysectomised amphibia.** W. J. ATWELL (Anat. Rec., 1935, 62, 361—379).—Thyrotropic hormone causes rapid and complete metamorphosis, but adrenotropic hormone produces only slight changes.

R. N. C.

**Metabolic aspects of thyroid-adrenal interrelationship.** S. B. BARKER, J. F. FAZIKAS, and H. E. HIMWICH (Amer. J. Physiol., 1936, 115, 415—418).—The rise of  $O_2$  consumption produced by adrenaline in rats is increased by thyroid feeding and decreased by thyroidectomy, this decrease being abolished by thyroid feeding.

R. N. C.

**Effect of antithyroidal protective substance on the Reid Hunt test.** K. FELLINGER and O. HOCHSTÄDT (Klin. Woch., 1935, 14, 1250—1251;

Chem. Zentr., 1935, ii, 3790).—By means of the MeCN reaction in mice it is shown that the antagonistic action of the protective substance in respect of the thyrotropic hormone is  $>$  in respect of the thyroid. The substance acts directly on the gland or on its regulating factors.

A. G. P.

**Detection of thyrotropic hormone in tissues other than of the pituitary.** A. STURM and W. SCHÖNING (Endokrinol., 1935, 16, 1—8; Chem. Zentr., 1935, ii, 3941).—Many tissues (notably of ovary and kidneys) contain a substance which regulates thyroid secretion. The presumed pituitary-sp. property of the thyrotropic hormone is discussed.

A. G. P.

**Effect of thyroxine on the tissue metabolism of excised *Limulus* heart.** J. E. DAVIS and A. B. HASTINGS (Amer. J. Physiol., 1936, 114, 618—619).—Metabolism *in vitro* is increased under suitable conditions. This is not due to increased work by the heart.

R. N. C.

**Comparison of the calorogenic potencies of *l*- and *dl*-thyroxine and thyroid gland.** Thyroxine content of the acid-soluble fraction of the peptic digest of thyroid protein. G. L. FOSTER, W. W. PALMER, and J. P. LELAND (J. Biol. Chem., 1936, 115, 467—477).—*l*-Thyroxine,  $[\alpha]_D -4.4^\circ$ , isolated from pig's thyroid, and equiv. doses of thyroid extract, have twice the calorogenic activity of *dl*-thyroxine in guinea-pigs. Thus only the *l*-compound is biologically active. The acid-sol. fractions of a peptic digest of thyroid protein still contain thyroxine, which may be carried down with protein ppt.

F. A. A.

**Glycogen content of liver and muscle in the completely hypophysectomised dog.** I. L. CHAIKOFF, G. F. HOLTOM, and F. L. REICHERT (Amer. J. Physiol., 1936, 114, 468—472).—Liver- and muscle-glycogen in well-nourished dogs is not altered by hypophysectomy.

R. N. C.

**Maintenance of carbohydrate levels in fasted hypophysectomised rats treated with anterior pituitary extracts.** J. A. RUSSELL and L. L. BENNETT (Proc. Soc. Exp. Biol. Med., 1936, 34, 406—409).—The abnormal fall in carbohydrate stores which occurs in fasting hypophysectomised rats is prevented by administration of anterior pituitary extracts. The muscle-glycogen may then reach vals.  $>$  those of the normal fasting level.

W. O. K.

**Relation of the pituitary gland to muscle-creatine.** B. G. SHAPIRO and H. ZWARENSTEIN (Proc. Roy. Soc. Edin., 1936, 56, 164—168).—The hamstring muscles of the right and left legs of *Xenopus laevis* contain on an average 0.399% of creatine (I). Muscle-(I) decreases by 15% 18 to 22 weeks after hypophysectomy, whilst daily injections of 0.2 c.c. of anterior lobe extracts cause an increase of approx. 30% 3 to 5 weeks after commencing injection. The anterior lobe of the pituitary and muscle-(I) may be indirectly related through some other endocrine organ.

J. N. A.

**Source of the blood-acetone resulting from administration of the ketogenic principle of the anterior pituitary gland.** I. A. MIRSKY (Amer. J.

Physiol., 1936, 115, 424—428).—The hormone acts only on the liver, without stimulating extra-hepatic fat oxidation. The muscles play no part in the accumulation of blood-ketones, production of which is probably due to decreased carbohydrate utilisation by the liver cells in presence of an increased catabolism of fatty acids arising from accelerated glycogenolysis in the liver. R. N. C.

**Effects of oestrus and spaying on pituitary metabolism.** J. VICTOR and D. H. ANDERSEN (Amer. J. Physiol., 1936, 115, 130—137).—The respiratory rate *in vitro* of the anterior pituitary is max. in pro-oestral, and min. in dioestral and spayed, animals. Anaerobic glycolysis and total pituitary metabolism in pro-oestral and oestral are > those in dioestral and spayed animals. R. N. C.

**Action of preparations from the posterior lobe of the pituitary gland on the imbibition of water by frogs.** F. K. OLDHAM (Amer. J. Physiol., 1936, 115, 275—280).—The oxytocic and, to a smaller extent, the pressor hormone cause imbibition; the melanophore-dilating hormone is not involved. R. N. C.

**Hormones and pregnancy.** W. C. MILLER (Vet. Rec., 1936, 48, 903—911).—A review. A. G. P.

**Biological assay of "international standard" oestrin and of certain commercial preparations.** F. E. D'AMOUR and R. G. GUSTAVSON (J. Pharm. Exp. Ther., 1936, 57, 472—481).—The rat unit of international standard oestrin is as follows: single injection in oil,  $1.3 \times 10^{-6}$  g.; multiple injection in oil  $1.5 \times 10^{-6}$  g.; single aq. injection  $3.8 \times 10^{-6}$  g., and multiple aq. injection  $0.74 \times 10^{-6}$  g. Aq. commercial preps. decrease considerably in activity on keeping. J. N. A.

**Effect of oestrin on the prostate gland of the albino rat and mouse.** D. WELLER, M. D. OVERHOLSER, and W. O. NELSON (Anat. Rec., 1936, 65, 149—163). R. N. C.

**Effect of oestrin on the activity of the anterior lobe of the pituitary.** H. L. FEVOLD, F. L. HISAW, and R. GREEP (Amer. J. Physiol., 1936, 114, 508—513).—Secretion of luteinising hormone is augmented, but not that of follicle-stimulating hormone. R. N. C.

**Gonad-hypophyseal complex in oestrin-injected rats.** S. R. HALPERN and F. E. D'AMOUR (Amer. J. Physiol., 1936, 115, 229—238). R. N. C.

**Persistence of corpora lutea in the pseudo-pregnant rabbit.** W. M. ALLEN and G. P. HECKEL (Science, 1936, 84, 161—162).—The persistence of corpora lutea produced by injection of oestrin (I) after a sterile mating indicates that in the rabbit the placenta elaborates (I) which, rather than a placental gonadotropic hormone, causes the corpora to persist. L. S. T.

**Comparative assay of oestrone in the rat and mouse.** A. M. HAIN and J. M. ROBSON (J. Pharm. Exp. Ther., 1936, 57, 337—346).—When oestrone (I) is given in 4 doses in oil, the rat unit is approx. 0.0033 mg., when similarly administered in 10% EtOH,

0.0025 mg. For the mouse the units are 0.00009 mg. and 0.00025 mg., respectively. Using oestrone benzoate (II), the rat unit is 0.005—0.01 mg., and for the mouse slightly < 0.0005 mg. With both species a single injection of (II) produces less effect than the same wt. of (I) given in 4 injections. The duration of the oestrus response and the relation between the rat and mouse units are discussed. J. N. A.

**Influence of oestrone on galactin content of male rat pituitaries.** R. P. REECE and C. W. TURNER (Proc. Soc. Exp. Biol. Med., 1936, 34, 402—403).—The pituitaries of normal male rats contain a definite quantity of galactin which is increased by subcutaneous injection of hydroxyoestrin benzoate (Oestroform B). W. O. K.

**Sterility in rabbits produced by injection of oestrone and related compounds.** G. PINCUS and R. E. KIRSCH (Amer. J. Physiol., 1936, 115, 219—228). R. N. C.

**Spectrophotometric determination of  $\alpha$ -oestrone and its derivatives.** M. SUREAU and P. GRANDADAM (Compt. rend., 1936, 203, 440—442).—The technique of Chevallier (A., 1935, 906) is adapted. Ultra-violet adsorption coeffs. are determined for  $\alpha$ -oestrone and for dihydro-oestrone and its benzoate. A. G. P.

**Isolation of principal oestrogenic substance of liquor folliculi.** D. W. MACCORQUODALE, S. A. THAYER, and E. A. DOISY (J. Biol. Chem., 1936, 115, 435—448).—Dihydrotheelin (I), previously isolated from sow ovaries as the *m*-bromobenzoate (Proc. Soc. Exp. Biol. Med., 1935, 32, 1182), is more easily isolated as the di- $\alpha$ -naphthoate. On hydrolysis (I) is obtained in pure cryst. form. (I) isolated from sow ovary is identical with that obtained from theelin. E. M. W.

**Action of a synthetic oestrogenic agent [9 : 10-dihydroxy-9 : 10-di-*n*-propyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthrene] on the anterior pituitary of the castrated female rat.** J. M. WOLFE (Amer. J. Physiol., 1936, 115, 665—669). R. N. C.

**Changes in tissue metabolism in oestral, dioestral, and spayed rats.** J. VICTOR, D. H. ANDERSEN, and M. R. PREST (Amer. J. Physiol., 1936, 115, 121—129).—O<sub>2</sub> consumption of the liver *in vitro* is max. in oestral and min. in spayed animals; the R.Q. is unaltered. Kidney metabolism does not vary. Infection increases O<sub>2</sub> consumption and the R.Q. of liver but not kidney. R. N. C.

**Effect of ovarian hormone on the basal metabolism of experimental hyperthyroidised rats.** T. C. SHERWOOD and L. M. BOWERS (Amer. J. Physiol., 1936, 115, 645—650).—The hormone induces a greater fall in basal metabolism when injected in oil solution than in aq. solution. It accelerates the return of basal metabolism to normal after thyroid feeding. R. N. C.

**Effects of two hypophyseal gonadotropic hormones on the reproductive system of the male rat.** R. O. GREEP, H. L. FEVOLD, and F. L. HISAW (Anat. Rec., 1936, 65, 261—271).—Follicle-stimulating hormone stimulates the germinal epithelium,

whilst luteinising hormone stimulates the interstitial cells to secrete the male hormone. R. N. C.

**Concentration and purification of the gonadotropic substance in urine of ovariectomised and post-menopausal women.** L. LEVIN and H. H. TYNDALE (Proc. Soc. Exp. Biol. Med., 1936, **34**, 516—518).—Gonadotropic material may be almost quantitatively pptd. by tannic acid from urine acidified by AcOH to  $p_H$  5.0. The ppt. is extracted with EtOH and then with COMe<sub>2</sub>. Purification of the crude tannate is described. W. O. K.

**Quantitative relation between follicle-stimulating and luteinising effects in castrate and menopause urine.** U. J. SALMON and R. T. FRANK (Proc. Soc. Exp. Biol. Med., 1936, **34**, 463—466).—Extracts from the urine of female castrates or women past the menopause produced follicle-stimulating and luteinising effects in rats' ovaries according to the dose given. W. O. K.

**Effect of divided dosage of gonadotropic extracts in the immature male rat.** F. BISCHOFF (Amer. J. Physiol., 1936, **114**, 483—487).

R. N. C.

**Industrial extraction of crystalline folliculin. Physical and biological determination.** D. VAN STOLK, H. PÉNAU, and R. L. DE LENCÈRE (J. Pharm. Chim., 1936, [viii], **24**, 249—266).—Pregnant mares' urine gives max. yields of the hormone (I) at the 5th—7th month of gestation (cf. Cole and Saunders, A., 1935, 1426). Colorimetric determination of (I) (Kober, A., 1931, 1195) is unsatisfactory with crude preps. A spectrometric method [(I) in EtOH has an absorption max. at 277.5 and min. at 247.5 mμ] and its application to the various stages of purification of (I) during its isolation from urine are described. F. O. H.

**Corpus luteum hormone.** K. EHRHARDT and A. HAGEN (Endokrinol., 1935, **16**, 51—60; Chem. Zentr., 1935, ii, 3788).—Impure extracts of human placenta give a positive Clauberg-Hohlweg reaction in 20% of cases examined, whereas after removal of follicular hormone 60% of positive tests are obtained. Extracts from pregnancy urine or that from tumour cases seldom contain the corpus luteum hormone; it could not be detected in urine after parenteral administration. A. G. P.

**Effect of progestin on the *in vitro* response of the rabbit's uterus to pituitrin.** A. W. MAKEPEACE, G. W. CORNER, and W. M. ALLEN (Amer. J. Physiol., 1936, **115**, 376—385). R. N. C.

**Preparation of non-toxic urine fractions for assay of male hormone by the female bitterling test.** I. S. KLEINER, A. I. WEISMAN, and D. I. MISHKIND (Science, 1936, **84**, 142).—Dialysis removes the factor toxic to fish in certain urines. L. S. T.

**Increasing the effectiveness of testosterone.** A. S. PARKES (Lancet, 1936, **231**, 674—676).—Testosterone acetate (I) and propionate (II) are much more effective than the free hormone in restoring the atrophic prostate and seminal vesicles of castrated rats. (II) has a more intense and prolonged action than (I). L. S. T.

**Sexual hormones. XVI. Esters of the testosterone and androsterone series. XVII. Bromination of sterol and androstene derivatives.**—See this vol., 1382.

**Effects of androgenic substances in the rat.** W. O. NELSON and T. F. GALLAGHER (Science, 1936, **84**, 230—232).—The effect of male hormone extracts on the testes of hypophysectomised rats, and the effect of androsterone, androstanediol, and androstenedione on the pituitary, mammary gland, and uterus of the spayed rat are described. L. S. T.

**Proposed synthesis of equilenin.**—See this vol., 1382.

**Inter-relationship of vitamins.** M. MITOLO (Boll. Soc. ital. Biol. sperim., 1936, **11**, 334—336).—The symptoms occurring in animals fed on diets rich in certain vitamins and lacking in others are described. Those of avitaminosis-*D* are modified by concomitant hypervitaminosis-*A*, -*B*, -*C*, or -(*A*+*B*+*C*) in the last case, a rachitic condition does not occur. F. O. H.

**Experimental polyavitaminosis.** G. PERETTI (Boll. Soc. ital. Biol. sperim., 1936, **11**, 338—339).—Symptoms of deprivation of one or more of the vitamins-*A*, -*B*, and -*C* in guinea-pigs are described. F. O. H.

**Choice of diet and production of experimental avitaminosis.** G. RIGOBELLO (Boll. Soc. ital. Biol. sperim., 1932, **7**, 825—830; Chem. Zentr., 1935, ii, 3791).—Suitable diets for inducing avitaminosis-*A*, -*B*, and -*D* are given. A. G. P.

**Relation of vitamin-*A* to eye development in the pig.** F. HALE (Amer. Soc. Animal Prod. Rec. Proc. 27th Ann. Meet., 1934, 126—128).—Defective eyes may result from -*A* deficiency in the mother or in the ration. CH. ABS. (*p*)

**Vitamin-*A* as a prophylactic against the common cold in groups of school children.** E. M. TRESS (Amer. J. Digest. Dis. Nutrition, 1935, **1**, 795—796).—Beneficial effects of feeding -*A* are recorded. CH. ABS. (*p*)

**Vitamin-*A* storage by chickens.** A. D. HOLMES, F. TRIPP, and P. A. CAMPBELL (Poultry Sci., 1936, **15**, 71—78).—The -*A* contents of livers of chickens of varying age and receiving -*A* supplements are recorded. High-producing flocks receiving a vitamin-rich diet can maintain a sufficient body reserve of -*A* through the reproductive period. A. G. P.

**Cytological study of the action of vitamin-*A*.** P. JOYET-LAVERGNE (Bull. Soc. Chim. biol., 1936, **18**, 1041—1054).—Vitamin-*A* as determined by the Carr-Price test is present in the nucleolus and chondriome of animal and vegetable cells. A. L.

**Photo-chemical decomposition of vitamin-*A* in alcoholic solution. II. Secondary reaction.** A. CHEVALLIER and P. DUBOULOZ (Bull. Soc. Chim. biol., 1936, **18**, 1115—1124; cf. this vol., 1159).—One of the two products produced by irradiation of vitamin-*A* with light of 365 mμ is further decomposed with shorter waves giving a series of products. A. L.

**Spectrophotographic studies on the antimony trichloride reaction for vitamin-A.** I. Relation between tintometer readings and spectral absorption of the blue solution. O. NOTEVARP and H. W. WEEDON (Biochem. J., 1936, 30, 1705—1718).—The absorption spectrum of the  $\text{SbCl}_3$ -vitamin-A complex changes with time and the variation in the intensity of the 618 and 572  $\mu$  bands depends on the prep. used. Empirical relations for the extinction coeffs. and the blue vals. are given for the different absorption max., and also a relation for the variation of the blue val. with -A concn. H. D.

**Determination of vitamins by chemical methods. I. Vitamin-A in vegetable and animal oils.** A. SANTOS RUIZ (Anal. Fis. Quim., 1934, 32, 1217—1224).—A review of the literature. Olive oil contains 3 "cod-liver-oil units" per 100 g. The vitamin-A content of animal and vegetable oils is related to the intensity and time of action of the solar rays to which they have been exposed. F. R. G.

**Nutritive effect of tunny, ox liver, and yeast on rats.** U. TANGE and K. MICHl (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 809—817).—Rats on a diet deficient in B vitamins do not grow so well when the ration is supplemented with tunny or ox liver as when with yeast. The growth-promoting actions of EtOH extracts of yeast were > those from fat-free ox liver, which in turn exceeded those from tunny liver. W. O. K.

**Intermediate metabolism of carbohydrates in avitaminosis-B.** I. G. PERETTI and F. PORRAZZO (Arch. Sci. biol., 1933, 19, 227—248; Chem. Zentr., 1935, ii, 3791).—Vitamin-B affects carbohydrate metabolism at a stage preceding that of lactic acid production. A. G. P.

**Multiple nature of the third factor of the vitamin-B complex.** S. LEFKOVSKY, T. H. JUKES, and M. E. KRAUSE (J. Biol. Chem., 1936, 115, 557—566).—Component I (separated from II by adsorption on fuller's earth) of rice-bran extracts prevented dermatitis in rats but was without effect on chickens, whereas II prevented the latter and aggravated the former in absence of I. The deficiency in rats with an EtOH extract of white corn as a source of vitamin-B was multiple in nature, the chief factor lacking being vitamin-B<sub>2</sub> (flavin). H. G. R.

**Extraction of vitamin-B<sub>1</sub> from adsorbates.** R. D. GREENE and A. BLACK (Science, 1936, 84, 185—186).—The best yields (< 90%) of vitamin from the adsorbate obtained in Seidell's method occur when aq., aq.-EtOH, or EtOH solutions of acid salts of  $\text{C}_6\text{H}_5\text{N}$ , quinine,  $\text{NH}_2\text{Ph}$ , etc. are used as extractants. The salt solutions have an effect > that of acid or base alone. L. S. T.

**Pathological changes in the eye in experimental vitamin-B<sub>2</sub> deficiency.** K. SEN, N. DAS, and B. C. GUHA (Sci. and Cult., 1935, 1, 59—60). CH. ABS. (p)

**Potassium in the brain in vitamin-B<sub>1</sub> deficiency.** H. W. KINNERSLEY (Nature, 1936, 138, 368).—No significant difference in the K content of the brains of normal and vitamin-B<sub>1</sub>-deficient pigeons has been detected (cf. A., 1934, 1042). L. S. T.

**Vitamin-B<sub>2</sub> concentrates as preventives of black-tongue.** L. E. BOOHER and G. H. HANSMANN (Amer. J. Physiol., 1936, 114, 429—435).—Vitamin-B<sub>2</sub> concentrate from low-lactose whey powder, which contains lactoflavin and at least one other thermostable vitamin necessary for growth of rats, prevents or cures black-tongue in dogs. It augments the inferior rate of growth produced in young rats by a diet causing black-tongue in dogs. Liberal quantities of nutritive protein in the diet apparently decrease the -B<sub>2</sub> requirements for growth of rats and prevention of black-tongue in dogs. R. N. C.

**Vitamin-B<sub>2</sub> from different sources and coccidian infection.** E. R. BECKER and N. F. MOREHOUSE (Proc. Soc. Exp. Biol. Med., 1936, 34, 437—439).—A substance promoting the development of the oocysts of *Eimeria mizairii* in rats is present in various vitamin-B<sub>2</sub> preps., but not in liver. W. O. K.

**Significance of vitamin-C in biological oxidation processes of the human lens.** P. WEINSTEIN (Orvosi Hetilap, 1935, 79, 874—875).—Vitamin-C, like cystine (I), disappears from the cataractous lens and is found in the covering. Reduced -C acts as a protective agent and retards the oxidation of (I). CH. ABS. (p)

**Reversible oxidation of vitamin-C in biological medium or pure solution.** N. BEZSSONOFF and M. WOLOSZYŃ (Compt. rend., 1936, 203, 275—277).—The decolorisation of dichlorophenol-indophenol by ascorbic acid in lemon juice is unaffected by change of  $p_H$ , but varies in pure solutions. The stability of the vitamin is increased in biological solutions by the presence of other reducing agents. The existence of an oxidised compound of -C,  $(\text{C}_6\text{H}_7\text{O}_6)_2$ , is postulated. P. G. M.

**Meat diet: blood as an antiscorbutic factor.** V. STEFANSSON (Science, 1936, 84, 227—228).—A discussion. L. S. T.

**Histochemistry. IX. Quantitative distribution of vitamin-C in the adrenal gland at various stages of development.** D. GLICK and G. R. BISKIND (J. Biol. Chem., 1936, 115, 551—555).—The concn. is highest in the fascicular zone. It increases in all portions of the gland during growth of the foetus and reaches a max. in the calf. The size and vitamin-C content of the cells increase regularly to the adult stage. H. G. R.

**Vitamin-C in an oestrin-producing ovarian tumour.** G. R. BISKIND and D. GLICK (Science, 1936, 84, 186).—The relatively low vitamin-C concn. of this tissue supports the view (this vol., 530) that -C is unrelated to oestrin formation in the human ovary. L. S. T.

**State of ascorbic acid in plant tissues.** G. L. MACK (Nature, 1936, 138, 505—506).—Repetition of the work of Guha and Pal (this vol., 1033) failed to reveal an increase in ascorbic acid (I) content on heating. The cabbages examined did not contain appreciable amounts of combined (I). When the oxidation enzyme is inactivated by heat or EtOH, or inhibited by extraction with sufficiently strong acid,

the total (I) is obtained. The apparent increase on cooking is due to inactivation of the enzyme.

L. S. T.

**Variation of vitamin-C content in certain fruits and vegetables.**—See B., 1936, 953.

**Ascorbic acid oxidase in determining vitamin-C in lens and aqueous humour.** L. ROSNER and J. BELLOWS (Proc. Soc. Exp. Biol. Med., 1936, 34, 493—494).—Treatment of extracts of the lens of the eye or of the aq. humour with the enzyme from the Hubbard squash which promotes the oxidation of ascorbic acid (I) (A., 1935, 1023) completely destroys their power of reducing Tillmans' reagent (II). The reducing substance in the lens and humour determined by (II) is therefore (I).

W. O. K.

**Use of the phosphotungstic acid method of determining ascorbic acid in urines with low ascorbic acid content.** G. MEDES (Biochem. J., 1936, 30, 1753—1755; cf. A., 1935, 1430).—The application of the reagent to urines of ascorbic acid content of  $<4 \times 10^{-4}$  g.-mol. per 100 ml. is described.

W. McC.

**Determination of ascorbic acid by titration with 2:6-dichlorophenol-indophenol (Tillmans' method).** R. STROHECKER and R. VAUBEL (Angew. Chem., 1936, 49, 666—668; cf. A., 1932, 310).—Details of the method given include standardisation of the dye (0.001*N*) with  $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2$ , prep. of tissue extracts by dil. AcOH, application of  $\text{PhNO}_2$  (in which the dye is sol.) to highly-coloured extracts, and appearance of the end-point under varying conditions.

F. O. H.

**Determination of vitamin-C by means of its influence on the body-weight of guinea-pigs.** K. H. COWARD and E. W. KASSNER (Biochem. J., 1936, 30, 1719—1727).—A method similar to that used for vitamin-A (A., 1932, 886) is described. The derived relationship is  $y = 74.3 + 108.2 \log (\log 10x)$ , where  $y$  is the mean wt.-increase in g. in 6 weeks and  $x$  is the daily dose of ascorbic acid in mg.; that between severity of scurvy and dose is also curvilinear. The method, however, is somewhat inferior to the "tooth" method.

F. O. H.

**Value of the acid silver nitrate reaction as a test for ascorbic acid.** A. GROUND and C. P. LEBLOND (Nature, 1936, 138, 247—248).—The absence of a coloration by acid  $\text{AgNO}_3$  is not necessarily a proof of the absence of ascorbic acid (I), but a positive reaction in tissue is a sp. test for (I).

L. S. T.

**Differential threshold of reaction to vitamin-D deficiency in the house-sparrow and the chick.** H. FRIEDMANN (Biol. Bull., 1935, 69, 71—74).—The possible antirachitic properties of the irradiated secretion of the uropygial gland are examined. The threshold of reaction of house-sparrows and starlings to vitamin-D deficiency is markedly different.

CH. ABS. (p)

**Mechanism of the action of irradiated ergosterol.** I. Development of bone and its mineral content; calcæmia and phosphatæmia. II. Lipin content of bone. L. ROBUSHI (Boll. Soc. ital. Biol. sperim., 1932, 7, 1025—1028, 1029—1032;

Chem. Zentr., 1935, ii, 3791—3792).—I. Administration of irradiated ergosterol (I) increases the Ca and P contents of blood but not those of bone.

II. (I) affects the lipin content of bone marrow.

A. G. P.

**Effect on the antirachitic activity of their milk when ewes were exposed to sunshine and ultra-violet rays.** W. G. KIRK, B. H. THOMAS, and C. C. CULBERTSON (Amer. Soc. Animal Prod. Rec. Proc. 27th Ann. Meet., 1934, 182—188).—Treatments produced no appreciable effect.

CH. ABS. (p)

**Vitamin-D requirements of calves when natural milk is the sole source of the antirachitic factor.** J. W. LONG, C. F. HUFFMAN, and C. W. DUNCAN (Milk Plant Month., 1936, 25, No. 7, 30—36).—Growing calves developed rickets when fed a rachitogenic ration containing the same Ca/P ratio as milk. The vitamin-D requirement of a growing calf  $\propto$  the rate of gain in body-wt. When winter or early spring milk supplied the only source of -D, 0.3—0.4 U.S.P. unit per lb. of body-wt. daily was sufficient for the requirements of a growing calf provided that the normal level of plasma-Mg was maintained. The higher -D requirement of calves on summer milk is tentatively associated with a difference in Mg metabolism.

W. L. D.

**Effect of source of vitamin-D in the diet of chicken on storage of the antirachitic factor.** G. M. DEVANEY, H. E. MUNSELL, and H. W. TITUS (Poultry Sci., 1936, 15, 149—153; cf. A., 1935, 1287).—The -D storage of egg yolk was not affected by 8% of fat in the diet. 8% of cod liver-oil (I) in the diet reduced the no., size, and hatchability of eggs. The -D in yolk increases with the (I) or viosterol (II) content of the ration. With a ration containing 2—4% of (I) or 8% of (II), approx. 2% of the ingested -D appeared in the egg yolk. With 2—4% of (II) or 8% of (I), -D storage in yolks was appreciably less although the -D potency of the yolk was increased.

A. G. P.

**Determination of vitamin-D. III. Effect of calcification on growth and sex differences in white Leghorn chicks.** L. L. LACHAT and H. A. HALVORSON (Poultry Sci., 1936, 15, 127—135; cf. A., 1935, 417).—Deficiency of vitamin-D affects growth and calcification in females  $>$  in males. Females utilise -D more efficiently than do males, and are more suitable for laboratory tests. Seasonal variations, previously reported, in the calcification of rachitic chicks are now explained on the basis of association between body-wt. and bone-ash content. In faster growing birds greater amounts of skeleton are developed and show greater relative amounts of mineral deposition in the skeleton. Results of the A.O.A.C. method of assay are accurately interpreted by means of a simple formula.

A. G. P.

**Factors producing rickets present in cereals.** O. RYGH (Bull. Soc. Chim. biol., 1936, 18, 1091—1096).—The free fatty acids (I) isolated from oats are antagonistic to the antirachitic action of those from green plants. Concn. of the rachitic factor in the unneutralised fraction of (I) was effected after partial neutralisation.

A. L.

**Vitamin-D in Baltic herring.** (A) G. BLIX, H. RYDIN, and G. ENGLUND. (B) G. BLIX and G. ENGLUND (Upsala läkareforen. forh., 1936, 40, 175—182; 42, 203—207).—The vitamin-D content of the herring oil was about 200 international units per g., and therefore comparable with that of good cod-liver oil. The fat content of the herrings was a max. at 7—9% in Sept. to Nov. and a min. at 3—6% in Feb. to April. Boiling the herrings in a min. amount of H<sub>2</sub>O did not affect the -D val. of the oil.

NUTR. ABS.

**Chemistry of calciferol and vitamin-D<sub>3</sub>.** A. I. BACHARACH (Nature, 1936, 138, 387—389).—A summary of recent work. L. S. T.

**Purification of the antihæmorrhagic vitamin by distillation.** H. J. ALMQUIST (J. Biol. Chem., 1936, 115, 589—591).—The active fraction of the lucerne-meal concentrate (cf. this vol., 907) distils at 120—145°/1 × 10<sup>-6</sup> mm. H. G. R.

**New factor, not vitamin-B<sub>12</sub>, necessary for hatchability.** R. B. NESTLER, T. C. BYERLY, N. R. ELLIS, and H. W. TITUS (Poultry Sci., 1936, 15, 67—70).—A mixed grain-lucerne meal ration contains sufficient vitamin-B<sub>2</sub> for hatchability, but lacks a factor necessary for high hatchability. This factor is present in dried pigs' liver and green grass, and, to a smaller extent, in fish meal, desiccated meat meal, and dried buttermilk, but not in whey.

A. G. P.

**Electrophoresis of plant cell-contents.** A. GUILLIERMOND and N. CHOUCROUN (Compt. rend., 1936, 203, 225—229).—An external field exerts little effect on the contents so long as the cell is living, but prolonged application of a powerful field kills the cell and electrophoresis occurs. On death the nucleus is normally attracted to the positive pole; addition of neutral-red, which is localised during life in the vacuole and is transferred to the nucleus on death, causes migration to the negative pole. P. G. M.

**Permeability of membranes.**—See this vol., 1335.

**Breakdown of fruit and vegetable tissue due to an electric current.** W. SEIFRIZ (Plant Physiol., 1936, 11, 195—200).—Tissues of fruits and vegetables when made the cathode of a 110-volt circuit break down to a soft, dark-coloured mass and show a uniform  $p_H$  of 12.2. When placed at the anode the tissues remain practically unchanged. The degeneration is attributed to auto-proteolysis catalysed by intracellular enzymes rendered active by reducing conditions at the cathode. Proteolysis is followed by enzymic oxidation and discoloration accelerated by the alkaline medium surrounding the cathode. Phenolic compounds are probably concerned. Potato and onion tissues gelatinise at the cathode and are not discoloured. A. G. P.

**Vernalisation.** F. G. GREGORY and O. N. PURVIS (Nature, 1936, 138, 249).—Embryos of cereals separated completely from the endosperm can be vernalised in the same way as complete seeds, showing that the cause of vernalisation by low temp. is inherent in the embryo and independent of the metabolism of the endosperm or aleurone layer. L. S. T.

**Creeping movements of *Spirogyra*.** D. R. CHESTERMAN and C. L. FOSTER (Nature, 1936, 138, 403—404).—Solutions of electrolytes of concn.  $\geq 1\%$  reduce the creeping of *Spirogyra* up the sides of the containing vessel in the dark. Sucrose and glucose up to a crit. concn. reduce climbing and then increase it. The results appear to be related to effects on the respiratory activity of the algal cells. L. S. T.

**Changes of apparent ionic mobilities in protoplasm. I. Effects of guaiacol on *Valonia*.** W. J. V. OSTERHOUT (J. Gen. Physiol., 1936, 20, 13—43).—On treatment with 0.01M-guaiacol the order of the apparent mobilities ( $K > Cl > Na$ ) in the non-aq. protoplasmic surface is reversed. On adding the same concn. to sea-H<sub>2</sub>O the p.d. of the cell changes from -10 to +28 mv. and then slowly returns, due to changes in the apparent mobilities of the org. ions in the protoplasm. H. G. R.

**Yield and composition of eared and earless maize plants in a selfed line segregating barren stalks.** R. J. GARBER, R. B. DUSTMAN, and C. R. BURNHAM (J. Amer. Soc. Agron., 1936, 28, 85—91).—The wt. and sugar content of stems and leaves of earless plants were > those of eared plants. In the entire plants eared individuals showed greater wt., carbohydrate content, and Et<sub>2</sub>O extract, but less crude protein. A. G. P.

**Dry matter production and metabolism in certain cultivated plants. III. Causes of nitrogen intake and protein formation.** S. ODÉN and K. SJOBERG (Kung. Landtbruks.-Akad. Handl. Tidskr., 73, 780—821; Chem. Zentr., 1935, ii, 3939).—In oats, beans, and cress, increasing N supplies cause increases in yield and total and % N, up to limiting vals. Small additions of N are converted almost completely into protein. The proportional conversion is smaller when large amounts of N are assimilated. A. G. P.

**Tissue function and organic solute movement in the sunflower.** O. A. LEONARD (Plant Physiol., 1936, 11, 25—61).—Diurnal and seasonal variations in the carbohydrate distribution in the plants are examined. Variation in concns. of simple sugars in leaves correspond with much smaller variations in sucrose (I). The (I) gradient is positive in bark and negative from head to seed. Storage of (I) occurs chiefly in bark, and that of simple sugars in pith. The starch content of all organs is very low except in leaves during the day. Acid-hydrolysable carbohydrate is a temporary storage form and is nearly all translocated from leaves at night. Pith effects storage of NO<sub>3</sub><sup>-</sup> and some synthesis of NH<sub>2</sub>-acids. Gradients of sol. N are positive from leaves to bark but those of total sol., NH<sub>2</sub><sup>-</sup>, and NH<sub>4</sub><sup>+</sup>-N are negative up the stem. Amide-N is never abundant and often absent. A. G. P.

**Production and physiology of Concord grape vines as affected by variations in the severity of pruning.** T. J. MANEY and H. H. FLAGGE (Proc. Amer. Soc. Hort. Sci., 1934, 32, 392—396).—No correlation was found between chemical composition and differences in fruitfulness. CH. ABS. (p)

**Influence of the chloride ion on the chlorophyll content of potato leaves.** S. BASSLAVSKAJA and M. SIROESCHKINA (Plant Physiol., 1936, 11, 149—157).—The chlorophyll (I) content of field-grown plants was 2—3 times that of pot-cultured plants. Heavy applications of Cl-containing fertilisers lowered the (I) content of field plants to an extent related to their increased  $H_2O$  content. The decrease in (I) content (%) of the dry matter of leaves occurred towards the end of the vegetative period. A. G. P.

**Chlorolytic action of serum.** M. E. SAUER (Plant Physiol., 1936, 11, 159—166).—Serum causes a liberation of chlorophyll (I) from cells of *Euglena gracilis* or *Protosiphon botryoides* if these have been sufficiently altered by contact with strong serum or by heat. The action is related to the lipin content of the serum. Immune serum does not increase the permeability of the cell to (I). A. G. P.

**Exudation in cucurbits.** A. S. CRAFTS (Plant Physiol., 1936, 11, 63—79).—The mechanism of phloem and xylem exudation is examined.

A. G. P.

**Absorption of water by the foliage of some common fruit species.** W. G. BRIERLEY (Proc. Amer. Soc. Hort. Sci., 1934, 32, 277—283).

CH. ABS. (p)

**Effect of ammonium- and of nitrate-nitrogen on the composition of the tomato plant.** H. E. CLARK (Plant Physiol., 1936, 11, 5—24).—In sand cultures the use of  $Ca(NO_3)_2$  as N source produced greater fresh wt. of plants but a slightly smaller % dry matter in fresh material.  $NO_3$ -fed plants contained more  $NO_3$ , ash, oxalic, malic, citric, and total org. acids, but less glutamine, asparagine, total  $NH_2-N$ , sol. org. and insol. protein-N than those receiving  $NH_4$ . The  $NH_4$  content was high in plants supplied with media of higher  $[NH_4]$ . Relations between absorption and assimilation of N, accumulation of ash constituents, and the synthesis of org. acids by plants are discussed.

A. G. P.

**Total nitrogen in developing flowers and young fruits of Valencia oranges.** S. H. CAMERON and D. APPLEMAN (Proc. Amer. Soc. Hort. Sci., 1934, 32, 304—207).—Flowers developing early contain more N than those developing later. The petals, stamens, and pistil of mature blossoms contain approx. 45, 30, and 25%, respectively, of the total N and dry matter.

CH. ABS. (p)

**Translocation of nitrogen in woody plants.** W. E. LOOMIS (Proc. Amer. Soc. Hort. Sci., 1934, 32, 61—64).—Much protein-N accumulated in the wood and bark of trees and was subsequently utilised in early spring growth. Movement of N from wood and bark was delayed by phloem rings and sol. org. N accumulated below the rings. Inorg. N can pass through normal cell membranes but org. N does not readily penetrate. Its upward and downward movement is confined to the plasmodesmal connexions between living cells, especially in phloem.

CH. ABS. (p)

**Mechanism of symbiotic nitrogen fixation.** A. I. VIRTANEN (Suomen Kem., 1936, 9, A, 69).—The N excreted by root nodules in sterile sand

culture consists of aspartic acid and lysine, with small amounts of  $NO_2$  derived from oximes. The first compound formed in N fixation is probably  $NH_2OH$ , which reacts with oxalacetic acid (derived from plant sugars) to produce the oxime and thence, by reduction, aspartic acid. A. G. P.

**Diagnosis of plant troubles with diphenylamine.** L. H. JONES (Plant Physiol., 1936, 11, 207—209).—Applications of the  $NHPh_2$  test in the examination of physiological disturbances involving N are described. Indications of a photochemical conversion of  $NH_4$  into  $NO_3$  within the plant are recorded.

A. G. P.

**Effect of boron on growth of certain green plants.** A. R. GÄIGEL (J. Agric. Univ. Puerto Rico, 1935, 19, 5—28).—In  $H_2O$  cultures of *Spirodela polyrrhyza* B was toxic at concns.  $>1$  p.p.m. and lethal at  $>5$  p.p.m. B caused chlorosis not corr. by Fe but partly cured by K tartrate. *Chlorella* was stimulated by 10 p.p.m. of B, larger proportions of which did not cause chlorosis. B did not lower the availability of Fe. Resistance of plants to B was increased by addition of glucose or sucrose to media.

CH. ABS. (p)

**Chemical and enzymic studies of the uneven ripening of Concord grapes.** J. E. WEBSTER, E. ANDERSON, and F. CROSS (Proc. Amer. Soc. Hort. Sci., 1934, 32, 365—369).—The principal chemical difference between green and coloured grapes is the lower sugar content of the former. CH. ABS. (p)

**Seasonal changes in Bartlett pear-leaves.** L. D. DAVIS and N. P. MOORE (Proc. Amer. Soc. Hort. Sci., 1934, 32, 131—138).—Ash constituents and N of leaves are examined at various growth stages. There was a consistent loss of N throughout the season especially after yellowing of leaves. CH. ABS. (p)

**Absorption, distribution, and seasonal movement of potassium in young apple trees: effect of potassium fertiliser on the potassium and nitrogen contents and growth of trees.** R. F. CHANDLER, jun. (J. Agric. Res., 1936, 53, 19—42).—Absorption of K by young trees  $\propto$  dry wt. increases. Relative amounts of K in new growth tended to increase and those of 1- and 2-year tissue to decrease throughout the season. In roots K decreased during rapid growth but increased in the later part of the season. The abs. amount of K in all parts of the tree increased with growth; that in leaves decreased after abscission began. New wood added by diameter growth corresponded with current twig growth in respect of [K]. The K content of old leaves was  $<$  that of new leaves. The increased intake of K by tissues following use of K fertilisers was in the order leaves  $>$  bark  $>$  wood. No growth differences could be attributed to the fertiliser. N absorption by trees continued late in the season, whereas K absorption ceased at leaf-fall. The N content of wood and bark decreased during summer through translocation to leaves, but K vals. remained approx. const.

A. G. P.

**Transformation of sugars in plants.** M. NURMIA (Suomen Kem., 1936, 9, A, 70).—Wheat, clover, oats, and horse beans, deprived of starch by storage

in darkness, when cut and placed in sugar solutions absorbed glucose or fructose, partly converted either sugar into the other, and synthesised sucrose (I). (I) was also produced in varying amounts from galactose and maltose, but not from xylose,  $\text{CO}(\text{CH}_2\text{OH})_2$ , or glycerol. The changes were not affected by PhMe and only slightly retarded by KCN. A. G. P.

**Changes in carbohydrate content of wheat plants during the process of hardening for drought-resistance.** I. M. VASSILIEV and M. G. VASSILIEV (Plant Physiol., 1936, 11, 115—125).—Hardening of wheat plants by growth with insufficient  $\text{H}_2\text{O}$  until wilting occurs resulted in an initial (24 hr. after wilting) increase in monosaccharides (I) and sucrose (II) and decrease in hemicellulose (III) contents. Subsequently, (II) decreased but (I) and (notably) (III) increased. Immediately after watering (I) decreased and (II) remained at a low level. Fully recovered plants showed lower  $\text{H}_2\text{O}$  and (I) but higher (II) and (III) contents than control plants. The significance of (III) in drought-resistance is discussed. A. G. P.

**Distribution of acetaldehyde and alcohol in the apple fruit.** E. V. MILLER (J. Agric. Res., 1936, 53, 49—55).—Vals. for various parts of different varieties of apples are given. Storage of prepared samples in refrigerators results in marked increase in  $\text{MeCHO}$  (I) content. Fruit affected with soft scald or soggy breakdown showed increased amounts of (I) in the peel. Recorded high vals. for (I) in peel are in part due to its production in cells ruptured in paring but accumulation of (I) in peel always follows injury by mechanical means or by physiological abnormality. A. G. P.

**Distribution of total soluble solids and catalase in different parts of Jonathan apples.** P. L. HARDING (J. Agric. Res., 1936, 53, 43—48).—The sol. solid content of apples was highest in the skin and decreased towards the pith. In fruit affected with soft scald all vals. tended to be < normal. Catalase activity in healthy apples was highest in skin and lowest in the region immediately beneath; in those showing soft scald max. activity occurred in the pith and min. vals. in the diseased portions. A. G. P.

**Photosynthesis of formaldehyde from "nascent carbon dioxide" in vitro: importance of respiration in photosynthesis.** A. RAM (Proc. Acad. Sci. U.P., 1934, 4, 83—94).—Solutions of  $\text{AcOH}$ , citric, malic, and lactic acids, glycine, glycogen,  $\text{COMe}_2$ , etc., malachite-green, Me-violet, methylene-blue, etc. produce  $\text{CH}_2\text{O}$  (I) on exposure to sunlight. Other simple acids, sugars, and starch produce much smaller amounts. The first group of substances probably produce (I) directly and the second group indirectly through  $\text{CO}_2$  and  $\text{H}_2\text{O}$  formed on oxidation. The bactericidal action of dyes may be due to formation of (I). Photosynthesis in plants is aided by energy derived from respiration. (I) is obtained photochemically from  $\text{CO}_3''$  or  $\text{HCO}_3'$  solutions much more readily in the presence of suitable exothermic reactions. CH. ABS. (p)

**Photosynthesis in relation to light and carbon dioxide.** E. L. SMITH (Proc. Nat. Acad. Sci., 1936, 22, 504—511).—A mathematical relationship is derived and compared with that applicable to other recorded data. The photosynthetic rate is the same function of both  $[\text{CO}_2]$  and light intensity.

A. G. P.

**Fluorescence of chlorophyll and its relation to photochemical processes in plants and organic solutions.**—See this vol., 1320.

**Oxidative metabolism of the colourless alga, *Prototheca zopfii*.** H. A. BARKER (J. Cell. Comp. Physiol., 1936, 8, 231—250).—Data are given for the  $\text{O}_2$  consumption and  $\text{CO}_2$  production corresponding with the assimilation of simple org. compounds by *P. zopfii*. The primary process of assimilation is the oxidation of the substrate to a carbohydrate, which is stored as glycogen, followed by a slower decomp. in the processes of cell synthesis. 50—80% of the substrate C is assimilated. E. A. H. R.

**Determination of carbon dioxide production in physiological plant studies.** F. L. WYND (Ann. Missouri Bot. Gdns., 1935, 22, 361—363).—Apparatus capable of detecting several g. of  $\text{CO}_2$  with an error of  $\pm 1$  mg. over a 12-hr. period is described.

CH. ABS. (p)

**Growth and respiration of the *Avena coleoptile*.** J. BONNER (J. Gen. Physiol., 1936, 20, 1—11).—During growth the rate of elongation decreases more rapidly than the respiration;  $\text{HCN}$  or phenylurethane affects both to the same degree. Transport of the hormone into the cell and its action on elongation depend on aerobic metabolism, the cryst. hormone having no effect on respiration. H. G. R.

**Respiration of ripening tomatoes.** B. N. SINGH and P. B. MATHUR (Current Sci., 1936, 5, 76—78).—The increased liberation of  $\text{CO}_2$  by ripening tomatoes is due to an accumulation of  $\text{CO}_2$  in the tissues together with a lessened resistance of the peripheral tissues to diffusion. Subsequently  $\text{CO}_2$  evolution declines, but the accumulation of  $\text{CO}_2$  in the fruit is still marked. Usual methods of measuring respiration rates are thus open to error. J. L. D.

**Effect of sulphur on rate of respiration and respiratory quotient in *Chilomonas paramecium*.** S. O. MAST, D. M. PACE, and L. R. MAST (J. Cell. Comp. Physiol., 1936, 8, 125—139).—S (present as  $\text{MgSO}_4$ ) is required for the respiration of *C. paramecium*, and probably functions in the oxidation of fat. Starch is transformed into fat, and S prevents the accumulation of the latter by causing its oxidation immediately on formation. E. A. H. R.

**Measurement of respiratory exchange in plants.** B. N. SINGH and P. B. MATHUR (Current Sci., 1936, 5, 20—22).—A simplification of the Haldane gas-analysis apparatus and the technique, as applied to these measurements, are described. D. C. J.

**Vegetable growth-promoting hormones.** F. KOGL (Svensk Kem. Tidskr., 1936, 48, 145—155).—A lecture. H. W.

**Action of  $\beta$ -indolylacetic acid on the development of seedlings.** T. SOLACOLU and D. CONSTAN-

TINESCO (Compt. rend., 1936, 203, 437—440).—Certain concns. of  $\beta$ -indolylacetic acid (I) retard the development of the radicle of *Phaseolus vulgaris*. Cultures in Knop's solution on cotton to which (I) is added produce a filamentous mycelium-like structure, the normal development of the radicle being entirely suspended. The filaments are derived from proliferations of superficial and meristematic tissue following disturbance of the orientation of tissues effected by (I). A. G. P.

Effect of phenylacetic acid on the growth of tomato plants. H. L. PEARSE (Nature, 1936, 138, 363—364).—Tomato plants sprayed with an aq. 0.1% solution of  $\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{H}$  show increased length of stem and petioles. The % of total dry wt. present as leaf and root are decreased whilst those as stem and petiole are increased. The  $\text{H}_2\text{O}$  content, but not the total dry wt., is increased. L. S. T.

Formation of nodules in legume roots. K. V. THIMANN (Proc. Nat. Acad. Sci., 1936, 22, 511—514).—Experimental data quoted indicate that the formation of nodules may result from the production of auxin in bacterially infected cells. A. G. P.

Relation of root pressure to plant disease. J. JOHNSON (Science, 1936, 84, 135—136).—A discussion. Internal  $\text{H}_2\text{O}$  relations of the host as determined by root pressure may be an important determining factor in predisposition to infection and development of disease. L. S. T.

Adaptation of the micro-Kjeldahl method for determining nitrogen in plant tissues. N. W. STUART (Plant Physiol., 1936, 11, 173—179).—Pregl's method gives results for the total and non-protein-N of plant materials with the same accuracy as does the macro-method. Basic N in plant extracts may be determined without digestion of the phosphotungstates and filter-paper. Amides are partly hydrolysed during distillation but total amide- $+\text{NH}_3\text{-N}$  may be satisfactorily determined. A. G. P.

Determination of basic nitrogen. Semi-micro-method applicable to plant tissues. W. W. UMBREIT and P. W. WILSON (Ind. Eng. Chem. [Anal.], 1936, 8, 361—362).—After removing peptides,  $\text{NH}_3$ , and amides the sap is treated with phosphotungstic acid in 5%  $\text{H}_2\text{SO}_4$  and cooled at 0—5° for 48 hr. The ppt. is filtered, dissolved in NaOH, and digested in a semi-micro-Kjeldahl flask with  $\text{H}_2\text{SO}_4$  containing 0.25% of  $\text{CuSO}_4$  and  $\text{SeO}_2$ . The method is accurate to 0.1—0.2 mg. of N. S. C.

Determination of small amounts of copper, especially in plants. E. STOLZE (Bodenk. Pflanzenernahr., 1936, 1, 115—132).—The dithiocarbazon (I) method (Fischer, A., 1934, 381) is applied to the examination of plant ash. Small amounts of  $\text{Fe}^{\text{III}}$  salts oxidise (I) and the product forms a Cu compound sol. in  $\text{CCl}_4$  and not removed with excess of (I) by washing with aq.  $\text{NH}_3$ . Treatment with  $\text{Na}_2\text{S}_2\text{O}_3$  reduces the oxidation product. The ratio of Cu in plants to Cu in soil is lower in Cu-rich areas. In the latter, snails have higher Cu and Mn contents. In pot cultures application of  $\text{CuSO}_4$  increased the Cu content of plants. The Mn content increased less uniformly. Spraying vines with Bordeaux mixture

increased the Cu and decreased the Mn in washed leaves. A. G. P.

Some ash constituents of alternate-bearing sugar prune trees. L. D. DAVIS (Proc. Amer. Soc. Hort. Sci., 1934, 32, 125—130).—The crop depletes the K and P in wood, bark, and spurs, but only K in leaves. The Ca and Mg contents of leaves are higher in bearing than in non-bearing trees.

CH. ABS. (p)

Correlation of organic and mineral matter contents of mulberry leaves. K. KATO (J. Agric. Chem. Soc. Japan, 1936, 12, 745—748).—The contents of  $\text{K}_2\text{O}$ ,  $\text{P}_2\text{O}_5$ , and  $\text{SO}_4$  are directly and those of CaO and  $\text{SiO}_2$  are inversely related to the amount of crude protein, whilst  $\text{Na}_2\text{O}$  is related to the carbohydrate sol. in HCl (*d* 1.15). J. N. A.

Plant roots give off organic acids. J. C. RATSEK (Proc. Amer. Soc. Hort. Sci., 1934, 32, 632—634).—When *Oxalis repens* was grown in  $\text{H}_2\text{O}$  cultures with media containing 100 and 250 p.p.m. of Ca (as  $\text{CaCl}_2$ ),  $\text{CaC}_2\text{O}_4$  was formed in the medium.

CH. ABS. (p)

Unsaturated fatty acids of hemp oil. Fixed oil from the seeds of *Celastrus paniculatus*, Willd.—See B., 1936, 1003.

Chemical investigation of the leaves of *Epi-medium macranthum* (Yin Yen Ho). Y. F. CHU and Y. S. KAO (J. Chinese Chem. Soc., 1936, 4, 312—321).—The EtOH extract of the leaves contains glucose, ceryl alcohol, hentriacontane, phytosterol, palmitic, stearic, oleic, and linoleic acids, and icarisside (?),  $\text{C}_{27}\text{H}_{32}\text{O}_{12}$ , m.p. 273—274° (Ac derivative, m.p. 149—151°), hydrolysed to anhydroicaritin (?), m.p. 219—220°. F. N. W.

Carbohydrates of *Allium* bulbs. V. Carbohydrates of *A. odorum* and *A. cepa*. VI. Chemical and physical properties of scorodose. Y. KIHARA (J. Agric. Chem. Soc. Japan, 1935, 11, 548—551, 552—557; cf. A., 1935, 1435).—V. The carbohydrate distribution is recorded for both species. The principal cold- $\text{H}_2\text{O}$ -sol. carbohydrate of bulbs of *A. odorum* is scorodose (I). None occurred in the leaves. (I) was not detected in bulbs of *A. cepa*.

VI. (I) from *A. scorodoprasum* has  $[\alpha]_D^{25} -41.54^\circ$  in  $\text{H}_2\text{O}$ , is pptd. by  $\text{Ba}(\text{OH})_2$  and  $\text{Ca}(\text{OH})_2$ , and is easily hydrolysed by dil.  $\text{H}_2\text{C}_2\text{O}_4$ . 0.3—0.5% HCl at 37° produced fructose from (I). Intestinal extracts and pancreatin hydrolysed (I) only very slowly.

CH. ABS. (p)

Polysaccharides of *Iridaea laminarioides*. III. T. TADOKORO and K. YOSHIMURA (J. Chem. Soc. Japan, 1935, 56, 655—658; cf. this vol., 534).—Polysaccharides sol. in 2% NaOH gave *d*- and *l*-erythrose on hydrolysis with 5%  $\text{H}_2\text{SO}_4$ .

CH. ABS. (p)

Constituents of *Actinidia callosa*, Lindl., var. *rufa*, Makino. Y. KIHARA (J. Agric. Chem. Soc. Japan, 1936, 12, 721—725).—An analysis of the bark and of sugars extracted with cold and hot  $\text{H}_2\text{O}$ , hot EtOH, and 5% KOH is given. The mucilage contains galactose and arabinose; the tannin from bark belongs to the pyrocatechol series. J. N. A.

Chile seed. W. A. BUSH (J. Amer. Chem. Soc., 1936, 58, 1821).—The seeds contain  $H_2O$  6.25, oil 26.1, and meal 67.65% (protein 28.92, fibre 29.1, ash 5.61, and carbohydrates 36.37%). The oil, which resembles tomato-seed oil, has  $d_{25}^{25}$  0.918,  $n_D^{25}$  1.4738, acid val. 2.18, I val. (Hanus) 133.5, Ac val. 7, sap. val. 192, and contains 1.7% of unsaponifiable matter. H. B.

Cyanogenetic glucosides in Australian plants. III. *Eucalyptus cladocalyx*. H. FINNEMORE, S. K. REICHARD, and D. K. LARGE (J. Proc. Roy. Soc. New South Wales, 1936, 68, 209—214; cf. A., 1930, 1627).—Fresh loppings of the young branches gave 0.32% (dried 0.5%) of HCN by maceration with  $H_2O$ , and no more by addition of the enzyme (I) of sweet almonds. After 7 years they gave only 0.06% (dried) in  $H_2O$  and 0.105% after addition of (I). Another fresh sample of young suckers gave after drying 0.5% of HCN. The isolation of prunasin (II) by percolation with  $COMe_2$  is described. One sample of *E. viminalis* leaves gave no HCN, another gave 0.09%. 10% of (II) is obtained from *Eremophila maculata*, best by  $COMe_2$ . R. S. C.

Reduced glutathione content of certain oil-bearing nuts. D. ZIMMET (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 135—136).—The reduced glutathione content of (peeled) walnuts, brazil nuts, hazel nuts, almonds, and arachis nuts was 20—40 mg. per 100 g. G. H. B.

Chemical examination of the Chinese drug, Tu Hao. Y. F. CHI and Y. M. LEE (J. Chinese Chem. Soc., 1936, 4, 305—311).—The  $EtOH$ -sol. portion contains glucose, phytosterol, palmitic, stearic, oleic, and linoleic acids. F. N. W.

Constitution of the Chinese drug, Hseh Tsuang seed. T. H. TANG (J. Chinese Chem. Soc., 1936, 4, 324—334).—From the light petroleum extract a basic unsaturated aromatic compound,  $C_{11}H_{10}(OH) \cdot OMe$ , m.p. 82.5—83.5° (*Ac* derivative, m.p. 85°; *Bz* derivative, m.p. 69°; *hydrochloride*, m.p. 102°; *dibromide*, m.p. 147.5—148°), is obtained. The  $Et_2O$ -sol. fraction consists of the glycerides of the following acids: saturated 4.56, oleic 46.25, and  $\beta$ -linoleic 45.81, and unsaponifiable matter 0.38%. F. N. W.

Dragon's blood. G. HESSE [with W. KLINGEL] (Annalen, 1936, 524, 14—24).—Extraction of the crude material with  $Et_2O$  followed by addition of light petroleum yields the crude resin (I). The acids which remain in the mother-liquors are transformed by boiling  $AcOH$  into abietic acid, m.p. 155—163°,  $[\alpha]_D^{25}$  —80.0° in 96%  $EtOH$ , whereas by crystallisation from  $COMe_2$  a product, m.p. 155—162°,  $[\alpha]_D^{25}$  —40.6° to —42.3° in  $EtOH$ , is obtained. Enrichment of (I) in pigment is effected by pptg. it from amyl alcohol-HCl by  $Et_2O$ , and chromatographic analysis (Brockmann's  $Al_2O_3$ ) of the product in  $CHCl_3$  affords the following substances: *dracocarmine*,  $C_{31}H_{26}O_5$  (also  $+1CHCl_3$ ), m.p. 293° (decomp.) somewhat dependent on the rate of heating (*hydrochloride*, m.p. >350°); *dracorubin*,  $C_{28}H_{24}O_7$ , decomp. 270—280° after changing colour at 220° (*hydrochloride*, decomp. 295°); an unidentified violet pigment. The substances do not appear to contain a sugar component. H. W.

Colouring matter of the corolla of *Rhododendron obtusum* f. *hinode*. I. Isolation of quercetin. K. HAYASHI (J. Pharm. Soc. Japan, 1933, 53, 1093—1098).—Quercetin is obtained from the  $MeOH-HCl$  extract after pptn. of anthocyanin with Ph. CH. ABS. (p)

Anthocyanin pigment of the winesap apple. I. J. DUNCAN and R. B. DUSTMAN (J. Amer. Chem. Soc., 1936, 58, 1511—1514).—The pigment, isolated from the skins by a modification of Willstätter and Burdick's method (A., 1917, i, 44), is idæin chloride (Willstätter and Mallinson, A., 1915, i, 282). H. B.

Polyene pigments of the orange. I. L. ZECHMEISTER and P. TUZSON (Ber., 1936, 69, [B], 1878—1884).—The ethereal oil from the skin is removed by steam-distillation in vac. or chromatographically if the isolation of cryptoxanthin (I) is not required. Partial success is achieved by chromatography of the total hydrolysed extract or by chromatography followed by hydrolysis of the separated zones. Whereas the native pigment is stable, certain polyene alcohols become changed immediately after separation from the pigment wax, probably owing to  $CO_2$  or traces of acid in the laboratory air. Many fractions resinify in  $CS_2$ . (I), zeaxanthin+lutein, and violaxanthin have been isolated, with a new carotenoid, *citraurin* [*oxime*, m.p. 181—182° (corr.)], probably a polyene OH-aldehyde formed by oxidation of a  $C_{40}$  compound in the tissue. H. W.

Composition of orange skins. P. R. v. d. R. COPEMAN (J. Pomology, 1936, 14, 205—215).—Spraying with Pb arsenate had no direct action on the skin constituents examined. Metabolic activity is greater in the pulp during the growing season. Supplies of Ca and P to the skin are probably accumulated during the early growth stages. Ca is associated with the structure of cell wall material. In the skin pectin is probably almost as important as sugar in metabolic processes. Sugar predominates in the pulp. A. G. P.

Isomerisation of carotenes by chromatographic adsorption. I.  $\psi$ - $\alpha$ -Carotene.—See this vol., 1369.

Carotenoid pigments of *Oscillatoria rubrescens*.—See this vol., 1369.

Pipi (Brazilian drug). R. A. D. DA SILVA (Rev. Flora med. Brasil., 1935, 1, 477—487; Chem. Zentr., 1935, ii, 3946).—The plant, *Petiveria tetrandra*, Gomes, contains a non-cryst. substance, *petiverin*, of alkaloid character. A. G. P.

Highly-active constituent of the bark of *Piscidia erythrina*. F. HAUSCHILD (Arch. exp. Path. Pharm., 1936, 182, 317—323).—Fractionation of the light petroleum-sol. substances gives a yellow amorphous prep. which is extremely toxic (approx. 20% < rotenone) to fish, rats, etc. (min. lethal dose in rats 0.1—0.3 mg. per 100 g.). Saponins present are not concerned in the toxicity excepting with fish. F. O. H.

New derivatives of the lignin from Spanish *Pinus sylvestris*. III. Spectroscopic study of the wood. L. LEMMEL (Anal. Fis. Quím., 1935, 33, 39—44).—An account of work previously reviewed (A., 1934, 335; 1935, 84). F. R. G.

**Examination by dark-ground illumination of the nuclei of cells grown *in vitro* and treated with hypotonic solutions.** O. M. OLIVO and M. BOSKOVICH (Boll. Soc. ital. Biol. sperim., 1936, 11, 243—245).—Hypotonic aq. NaCl renders invisible the nuclei and, more slowly, the nucleoli of fibroblasts of chick embryo; the effect is due to change in osmotic pressure. F. O. H.

**Influence of grain size, separation, and distribution on the capability of enlargement of photomicrographs of biological objects.**—See this vol., 1348.

**Relative acidity of histological fixing fluids.** A. PETRUNKEVITCH and G. E. PICKFORD (Anat. Rec., 1936, 65, 461—465).—The  $p_H$  of a no. of fluids are listed. R. N. C.

**Staining of the nuclei of cells grown *in vitro*, treated with hypertonic solution, and examined under dark-ground illumination.** O. M. OLIVO and M. BOSKOVICH (Boll. Soc. ital. Biol. sperim., 1936, 11, 245—247).—Modifications occurring in stained preps. are described. F. O. H.

**Isotonic solutions of colloidal silver.** R. DESCHASSEAUX (J. Pharm. Chim., 1936, [viii], 24, 268—269).—A stable prep. is afforded by adding 1.4 c.c. of 5% aq.  $Na_2S_2O_4$  ( $Na_2S_2O_3$  ?) and 0.10 g. of colloidal Ag (French Codex) to 90 c.c. of 10% aq. NaCl, the vol. being made up to 100 c.c. with  $H_2O$ . F. O. H.

**Ashing of plant material.** W. D. STEWART and J. M. ARTHUR (Contr. Boyce Thompson Inst., 1936, 8, 199—215).—Ashing at 450° in  $O_2$  gives more trustworthy results than ashing in a muffle at 650°. Volatilisation losses at the higher temp. were due to  $CO_2$  and  $Cl$ . At 450° there was no loss of KCl,  $K_2CO_3$ ,  $MgCO_3$ ,  $CaCl_2$ , or  $CaCO_3$ . At higher temp. some KCl and  $CaCl_2$  were lost. All sulphates were stable at all temp. examined. Addition of  $H_2SO_4$  to facilitate ashing in the determination of total bases was unsatisfactory owing to non-volatilisation of  $H_3PO_4$ . A method of ashing in an electric furnace in a current of  $O_2$  is described. A. G. P.

**Macro-Kjeldahl nitrogen determination.**—See this vol., 1397.

**Nitrogen not titratable by Kjeldahl's method.** F. SERIO and S. FIANDACA (Biochim. Terap. sperim., 1933, 20, 201—215; Chem. Zentr., 1935, ii, 3956).—Determination of N by elementary analysis gives higher results with urine (especially diabetic) than a wet method; the difference is ascribed to compounds containing nuclear N. H. N. R.

**Prevention of foaming in distillations.** W. M. BENDIEN (Chem. Weekblad, 1936, 33, 547).—Troublesome foaming in micro-Kjeldahl determinations of blood-albumin is prevented by the addition of 3—5 drops of a 0.5% solution of cholesterol in EtOH to each 20 c.c. of liquid. S. C.

**Determination of lactic acid, and, in particular, lactacidæmia.** C. PI-SUNER BAYO and J. F. PI (Anal. Fis. Quim., 1934, 32, 843—857).—The influence on the method of Friedemann *et al.* (A., 1927, 800; 1929, 677; 1933, 488) of the procedure for removing

proteins (the Folin-Wu method is recommended), duration of the oxidation by  $KMnO_4$ , and the efficiency of the cooling of the receiver is discussed, and the necessity for a blank determination is emphasised. The technique used is described and typical analyses of Zn lactate and blood are recorded. F. R. G.

**Determination of formic, acetic, and propionic acids in bacteriological culture media.** A. TASMANN (Chem. Weekblad, 1936, 33, 574—576).—The sample is acidified with  $H_2SO_4$  and phosphotungstic acid to ppt. proteins, centrifuged, and the clear solution steam-distilled. Total acids are determined in the distillate by titration, and  $HCO_2H$  by pptn. with  $HgCl_2$ . A separate sample of distillate is treated with  $K_2Cr_2O_7$ — $H_2SO_4$  to remove  $HCO_2H$ , and  $AcOH$  and  $EtCO_2H$  are determined by the "half distillation val." method. S. C.

**Colorimetric determination of uric acid (Folin) with delayed colour-formation.** G. BERGANI, E. BOERI, and P. BAER (Boll. Soc. ital. Biol. sperim., 1936, 11, 277—279).—Curves giving the increase in colour with time for standard amounts of uric acid (I) are applied to the determination of (I) by Folin's method (A., 1933, 845). F. O. H.

**Nickel nitroprusside as external indicator for iodometric determination of reduced glutathione.** D. ZIMMET (Arch. Sci. phys. nat., 1936, [v], 18, Suppl., 132—134).—The indicator is added to a series of tubes each containing 2 c.c. of the neutralised tissue extract with amounts of 0.002N-I differing by 1 drop, the approx. amount of I required being determined by preliminary titration. The end point is reached when the ppt. after centrifuging is no longer coloured rose. The sensitivity, 1 in  $4 \times 10^6$ , is dependent on exact neutralisation to bromothymol-blue. G. H. B.

**Determination of glutathione in biological material.** F. HARTNER and E. SCHLEISS (Mikrochem., 1936, 20, 163—179; cf. A., 1935, 422).—The quantity of I which reacts with glutathione (I) varies with the conditions, but Br from  $NaBr + KBrO_3$  gives const. vals. (I) in biological fluids is adsorbed on  $Cd(OH)_2$  or  $AgCl$  and determined by the Br method. Details of macro- and micro-methods are given. R. S.

**Micro-determination of cholesterol as pyridine cholesteryl sulphate.** A. E. SOBEL, I. J. DREKTER, and S. NATELSON (J. Biol. Chem., 1936, 115, 381—390).—Free cholesterol (I) is separated from its esters and other lipins by conversion into  $C_5H_5N$  cholesteryl sulphate and pptn. with light petroleum. The (I) in the ppt. is determined by the Liebermann-Burchard reaction. The (I) obtained from hydrolysis of the esters is separately determined. The advantages of this over the digitonin method are discussed. E. M. W.

**Electrolytic enrichment of arsenic in biological fluids.** J. VAN CALKER and A. PITTONI (Biochem. Z., 1936, 286, 297—300).—A method is described whereby traces of As in biological fluids can be collected at the anode and so conc. prior to determination. P. W. C.

# BRITISH CHEMICAL ABSTRACTS

## A.—PURE CHEMISTRY

DECEMBER, 1936.

### General, Physical, and Inorganic Chemistry.

**Effects of pressure and current on the intensities of the Balmer lines of hydrogen.** W. W. JACKSON (Phil. Mag., 1936, [vii], 22, 633—654).—A detailed investigation indicates that thermodynamic equilibrium is not established in a discharge tube; the excitation function governs the variation of the intensities of the lower members of the Balmer series. The ratio of the no. of dispersion electrons associated with  $H_\alpha$  and  $H_\beta$  is 5.07 at 0.18 mm. and 675 ma. N. M. B.

**Spectrum of doubly excited helium.** A. T. KIANG, S. T. MA, and T. Y. WU (Physical Rev., 1936, [ii], 50, 673).—None of the calc. strongest lines was found when electrons from a hot cathode were accelerated through low-pressure He with 1100—1800 volts corresponding with an electron energy on impact of 500—700 volts, for which the calc. excitation cross-section is a max. Probable explanations of the failure are discussed. N. M. B.

**Zeeman effect in the first negative oxygen bands.** L. BOZÓKY and R. SCHMID (Physical Rev., 1935, [ii], 48, 466).—The Zeeman effect in the 5631 Å. band has been photographed. L. S. T.

**Additional first negative oxygen bands.** L. BOZÓKY and R. SCHMID (Physical Rev., 1935, [ii], 48, 465).—Nine additional bands have been recognised. L. S. T.

**Dependence of intensities of rotation lines of a band on the conditions of excitation.** H. BRINKMAN (Physikal. Z., 1936, 37, 726—728).—The anomaly in the intensity distribution of rotation lines of  $N_2$  bands with different conditions of excitation, noticed by Herrmann (this vol., 261), is due to experimental error. The individual rotation lines of a band have the same abs. efficiency. A. J. M.

**Dependence of intensities of rotation lines of a band on the conditions of excitation.** O. HERRMANN (Physikal. Z., 1936, 37, 729).—A reply to Brinkman (preceding abstract). A. J. M.

**Effect of temperature on absorption of resonance radiation by sodium atoms.** J. L. TUCK and E. WARHURST (Trans. Faraday Soc., 1936, 32, 1501—1503).—The variation with temp. of absorption of resonance radiation by Na atoms has been determined for const. atom density between 140° and 320°. The absorption decreases linearly with temp. over this range. A. J. E.

**Absorption of sulphur vapour between 3600 and 5000 Å.** B. ROSEN and L. NEVEN (Compt.

rend., 1936, 203, 663—665; cf. A., 1928, 687).—The C bands are attributed to the principal system of  $S_2$ , and are present even at 1100°, when the band intensity depends only on the no. of  $S_2$  mols. and not on the concn. Recorded contradictory observations may be reconciled by the existence of a continuous region of absorption due to polyat. S situated in the same spectral region as the predissociated bands of the principal system. R. S. B.

**Glow spectra of halogen molecules.** Y. UCHIDA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 30, 71—82).—The vapours of  $I_2$  at >1200°,  $Br_2$  at >450°, and  $Cl_2$  at >1200° emit a glow consisting of emission bands superimposed on an independent continuum. The emission bands are due in each case to the transition  $O_u^+ \rightarrow$ , the  $O_u^+$  mols. arising from thermally dissociated  $^2P_{3/2}$  atoms by the successive ternary collision processes  $3X(^2P_{3/2}) \rightarrow X_2(^1\Sigma^+) + X(^2P_{1/2}) + \text{kinetic energy}$ ;  $X(^2P_{1/2}) + X(^2P_{3/2}) + \text{wall} \rightarrow X_2(O_u^+) + \text{wall} + \text{kinetic energy}$ . J. S. A.

**Absorption spectrum of chlorine.** C. F. GOODEVE and B. A. STEPHENS (Trans. Faraday Soc., 1936, 32, 1517—1518).—The absorption of thick layers of  $Cl_2$  between 600 and 1150 m $\mu$  has been investigated. The band system at 579—614 m $\mu$  (A., 1923, ii, 48) was not confirmed. Additional bands conforming to Birge and Weizel's analysis are given. A. J. E. W.

**New terms in the arc spectrum of tellurium.** S. G. KRISHNAMURTY (Indian J. Physics, 1936, 10, 365—373).—Full data for the range 1600—5000 Å. arc tabulated, and 8 new odd levels in addition to those due to 5d and 6s configurations are reported. N. M. B.

**Near ultra-violet band spectra of iodine.** O. STUHLMAN, jun. (Physical Rev., 1935, [ii], 48, 381).—The results of an examination of the emission spectrum of I vapour under high-frequency electrodeless discharge conditions are given. L. S. T.

**Arc spectrum of tungsten.** D. D. LAUN (Physical Rev., 1935, [ii], 48, 572).—The structure obtained from the Bureau of Standards measurements is summarised. S. T.

**Characteristics of mercury-rare gas discharge tubes.** H. W. MELVILLE (Trans. Faraday Soc., 1936, 32, 1525—1531).—The characteristics have been determined to find optimum conditions for a tube taking an input of 400 watts and emitting the resonance line at 2537 Å. For an input of 70 watts it is possible to obtain an output of  $10^{19}$  quanta per

sec. The mechanism of the collision processes occurring is discussed. E. S. H.

Characteristics of mercury arc between solid electrodes. W. ENDE (Z. tech. Physik, 1934, 15, 601—604; Chem. Zentr., 1936, i, 511).—The characteristics of an arc between oxide electrodes were studied. H. J. E.

Forbidden lines in the spectrum of neutral lead with high-frequency excitation. H. NIEWONNICZANSKI (Acta phys. polon., 1934, 2, 375—382; Chem. Zentr., 1936, i, 505; cf. A., 1935, 138). H. J. E.

Photographic and spectroscopic investigation of arcs with high current density. B. KIRSCHSTEIN and F. KOPPELMANN (Z. tech. Physik, 1934, 15, 604—606; Chem. Zentr., 1936, i, 511). H. J. E.

Change of striking potential on illumination. I. W. FÜCKS and W. SEITZ (Z. Physik, 1936, 103, 1—17).—The striking voltage in A, He, N<sub>2</sub>, and air for the electrode materials Ag, Cu, Ni, and Zn has been determined. Under most conditions the voltage was increased by illumination with Hg lamp ultra-violet light, that of short  $\lambda$  alone being effective. A. E. M.

Disappearance of spectral lines in strong electric fields. V. FABRIKANT (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 215—217; cf. A., 1930, 828; 1931, 1203).—Theoretical. Lanczos' wave-mechanical treatment is based on incorrect assumptions; Smurov's classical expression  $0.086e/\rho^2$  ( $e$ =electronic charge,  $\rho$ =orbital radius) for the potential required to ionise an H atom yields vals. agreeing with those required to cause the disappearance of the corresponding spectral lines. R. C. M.

Light wave-length measurements with a divergent beam and plane grating. D. L. DAS (Z. Physik, 1936, 101, 447—455). A. B. D. C.

Luminescence of solid substances produced by direct excitation in a Geissler tube. M. SERVIGNE (Compt. rend., 1936, 203, 581—583).—Ultra-violet Hg light is produced in the tube containing the solid by passing a discharge through the contained Ne or A saturated with Hg vapour. The specimen emits cathode luminescence when the pressure is 0.01 mm. The spectral bands emitted by a substance under the influence of these different radiations are generally the same, but the distribution of intensity is changed. J. G. A. G.

Townsend coefficients and spark discharge. D. Q. POSIN (Physical Rev., 1936, [ii], 50, 650—658).—A quant. study has been made of the pre-spark current between plane parallel electrodes in purified N<sub>2</sub>. Data for  $X/p$ ,  $\alpha/p$ , and  $\beta/p$ , where  $X$  is the field strength, and  $\alpha$  and  $\beta$  the Townsend coeffs., are tabulated and plotted, and are discussed in relation to the Townsend equation. N. M. B.

Yield of the characteristic X-rays of aluminium (Al K lines) excited by protons. O. PETER (Ann. Physik, 1936, [v], 27, 299—311).—The yield of emitted quanta per proton falling on Al has been found to be  $(6.22 \pm 0.31) \times 10^{-6}$  for excitation of the Al K lines by protons of 132 e.k.v. energy. This is in

agreement with the theory of Henneberg (A., 1934, 127). O. D. S.

Röntgen emission spectra and chemical combination. IV.  $K\alpha_1\alpha_2$  lines of phosphorus compounds. O. LUNDQUIST (Z. Physik, 1936, 102, 768—771).—In compounds of P the  $K\alpha_1\alpha_2$  doublet is shifted towards shorter  $\lambda$ . Compared with red P the mean shifts are, 1.58 X for hypophosphite, 2.19 X for phosphite, and 2.49 X for phosphate. H. C. G.

Fine structure in the K X-ray edge of gallium. W. W. MUTCH (Physical Rev., 1935, [ii], 48, 569—570).—A preliminary report of absorption spectra near the Ga K edge investigated at  $-150^\circ$  and  $-67^\circ$ . L. S. T.

Probability of K-shell ionisation of silver by cathode rays. H. S. W. MASSEY and E. H. S. BURHOP (Physical Rev., 1935, [ii], 48, 468; cf. this vol., 656). L. S. T.

L-Series for uranium. H. CLAESSON (Z. Physik, 1936, 499—508). A. B. D. C.

X-Ray satellites, relative intensities, and line widths. L. G. PARRATT (Physical Rev., 1936, [ii], 50, 598—602; cf. this vol., 1041).—Preliminary data on the  $L\alpha_{1,2,3,4,5,6,7}$  lines for Ag (47), and on the  $M\alpha, \beta$  lines for Au (79), recorded with a two-crystal spectrometer, are reported and discussed. N. M. B.

Feeble emissions in the L spectrum of radium (88). H. HULUBEI (Compt. rend., 1936, 203, 665—667; cf. this vol., 1169, 1311).—Satellites of  $\alpha_1, \beta_2$ , and  $\gamma_2$  rays have been observed with Ra. R. S. B.

$M_{IV, V}$  Absorption edges of protoactinium (atomic number 91). V. DOLEJŠEK and V. KUNZL (Nature, 1936, 138, 590). L. S. T.

Atomic dispersion and absorption of X-rays according to the relativistic wave mechanics of Dirac. I. K. SEILER (Ann. Physik, 1936, [v], 27, 329—372).—Mathematical. The component of at. absorption and dispersion of X-rays due to the K level is calc. Agreement with experimental vals. of the scattering coeff. in the neighbourhood of K lines is good for light and medium atoms. For heavy atoms relativity and spin effects must be taken into account. O. D. S.

Absorption of X-rays in the anticathode of the ion tube at low voltage. V. KUNZL (Acta phys. polon., 1934, 2, 447—457; Chem. Zentr., 1936, i, 718).—The  $M_{II}$  lines of Ta, Tm, and Pt and the  $L_I, L_{II}$ , and  $L_{III}$  lines of Sn were not observed in absorption. Only the  $L_I$  line of Mo was observed. H. J. E.

Production of polarised X-rays. W. H. GEORGE (Proc. Roy. Soc., 1936, A, 156, 96—107).—An account is given of the method used to get a  $10^3$ -fold increase in the intensity of the polarised beam obtainable from a given initial X-ray intensity, so that the beam is strong enough to use for the study of vectorial phenomena in the interactions of X-rays and matter. L. L. B.

Intensity of the central spot produced by X-rays penetrating piezoelectrically oscillating

quartz crystals. G. E. M. JAUNCEY and A. T. JAKES (Physical Rev., 1936, [ii], 50, 672).—Causes of variation of intensity and area of the central spot were investigated. The increases found by Fox (cf. A., 1935, 1059) were probably due to an accidental combination of photographic reversal and halation.

N. M. B.

Double Compton scattering. F. BORP (Naturwiss., 1936, 24, 680—681).—The scattered radiation from Pb at an angle of  $114^\circ$  is considered. The intensity of double scattered radiation for thin films increases more rapidly than with the square of the distance.

A. J. M.

Photo-electric properties of barium and calcium. N. C. JAMISON and R. J. CASHMAN (Physical Rev., 1936, [ii], 50, 624—631).—With repeated fractional distillation of Ba in a photo-electric cell, the work function at room temp. was 2.520 and 2.510 e.v., the difference being attributed to differences in crystal structure or in purity. Measurements at room temp. to  $100^\circ$  gave a temp. coeff. of  $(2.2 \pm 0.7) \times 10^{-5}$  e.v. per  $1^\circ$ . The abs. photo-electric yield of the surface was determined. The optical reflexion coeff. varied 43—63% over 4000—7000 Å. The work function of a Ca surface prepared by single distillation was 2.706 e.v. After repeated surface heating to  $100^\circ$ , the data did not fit Fowler's theoretical curve, the discrepancy indicating surface inhomogeneity. Analysis of data indicates two emitting surfaces having work functions differing by approx. 0.2 e.v.

N. M. B.

Dependence of the field electron stream on the work of emission. E. W. MULLER (Z. Physik, 1936, 102, 734—761).—Measurements were made of electron emission from Ba, Mg, and Cs on W. The results are somewhat at variance with wave-mechanical theory.

A. E. M.

Irregularities in thermionic emission from tungsten. F. L. YERZLEY (Physical Rev., 1936, [ii], 50, 610—616; cf. Johnson, this vol., 553).—A tube with a moving electrode is used to investigate variations in emission density over a length of W filament. Above a crit. temp. range positive ion emission is limited to narrow regions near the wire connections. Electron emission, even after careful filament ageing, is not uniform from point to point, but occurs in a stable pattern, with irregularities, the causes of which are discussed.

N. M. B.

Where can negative protons be found? F. ZWICKY (Physical Rev., 1935, [ii], 48, 169).—Negative protons should be sought in cloud chambers at high altitudes.

L. S. T.

Free atoms and molecular dissociation in high frequency discharges. A. A. BALANDIN and J. EIDUS (Acta Physicochim. U.R.S.S., 1936, 4, 527—546).—The instantaneous pressure increase on starting a high-frequency discharge was studied for discharges through a no. of pure and mixed bimol. gases and Ne. The effect, observed with all bimol. gases, is dependent on the nature of the electrodes, the initial pressure of the gas, and the current and voltage in the secondary. No effect is observed with Ne. The presence of H atoms in the discharge

through  $H_2$  is indicated by the reduction of  $MoO_3$  in the discharge tube.

O. D. S.

Possibility of a unified interpretation of electrons and protons. V. ROJANSKY (Physical Rev., 1935, [ii], 48, 108—109).—Theoretical.

L. S. T.

Polarisation of electrons by double scattering. O. HALPERN and J. SCHWINGER (Physical Rev., 1935, [ii], 48, 109—110).

L. S. T.

Absorbability of energy-rich electrons. M. WALDMEIER (Helv. phys. Acta, 1935, 8, 517—518; Chem. Zentr., 1936, i, 9).—The mass absorption coeff. of high-speed electrons in Pb is much  $>$  in Al, in qual. agreement with the theory of Bethe and Heitler.

J. S. A.

Behaviour of oxygen on electron bombardment. N. NEKRASSOV and I. STERN (Acta Physicochim. U.R.S.S., 1936, 4, 283—300).— $O_2$  in a three-electrode discharge tube at pressures 0.01—0.03 mm. is adsorbed on metal surfaces at 150—200°. On electron bombardment activated  $O_2$  mols. are formed and the pressure sinks rapidly. The velocity of decrease is greatly reduced by decreasing the surface of the Pt anode. The nature of the excited  $O_2$  mols. and the behaviour of secondary electrons are discussed.

R. S. B.

Space charge for electrons with initial velocities. G. PLATO, W. KLEEN, and H. ROTHE (Z. Physik, 1936, 101, 509—520).

A. B. D. C.

Scattering of high-speed electrons of varying energy. H. J. YEARIAN and J. D. HOWE (Physical Rev., 1935, [ii], 48, 381—382).—The atom factor of Au and Ag at different voltages has been investigated.

L. S. T.

Electron diffraction by gas molecules. I. Structure of phosphorus. II. Valency angle of oxygen. L. R. MAXWELL, V. M. MOSLEY, and S. B. HENDRICKS (Physical Rev., 1935, [ii], 48, 476; cf. this vol., 17).

L. S. T.

Electron velocity distribution in gases. K. G. EMELEUS and R. J. BALLANTINE (Physical Rev., 1936, [ii], 50, 672—673).—Druyvesteyn's method of analysis, applied to probe data for arcs and glows with electron concns. of  $10^7$ — $10^9$  per c.c., shows the frequent existence of a wide depression in the distribution function for electron velocities rather  $>$  the mean, as predicted by Morso (cf. A., 1935, 1294), and the common occurrence of a fairly distinct group of electrons of mean energy order 5—10 e.v., in accordance with the quantum theory of ionisation.

N. M. B.

Use of complex Riemannian geometry in the theory of the electron. U. KAKINUMA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 30, 83—98).

J. S. A.

Carbon reactions and the corrected mass scale. M. A. TUVE and L. R. HAFSTAD (Physical Rev., 1935, [ii], 48, 106—107).—The reactions of C under deuteron bombardment are discussed in relation to the new mass vals. (cf. this vol., 1171).

L. S. T.

At. wt. of molybdenum. Analysis of molybdenum pentachloride. O. HONIGSCHMID and G.

WITTMANN (Z. anorg. Chem., 1936, 229, 65—75).—The mean of 19 nephelometric titrations of  $\text{MoCl}_3$  with  $\text{AgNO}_3$  gives Mo  $95.95 \pm 0.004$  (Ag 107.880, Cl 35.457). F. L. U.

At. wt. of erbium. O. HÖNIGSCHMID (Naturwiss., 1936, 24, 619).—By titration of impure  $\text{ErCl}_3$  with  $\text{AgNO}_3$ , and correcting for Y and Tm content, the val. 167.24 was obtained for the at. wt. of Er. This is in agreement with the mass-spectrograph val. The previous low val. (165.2) is ascribed to impurity in the Er prep. A. J. M.

At. wt. of tungsten. Analysis of tungsten hexachloride. O. HÖNIGSCHMID and W. MENN (Z. anorg. Chem., 1936, 229, 49—64).—The purification of W by fractional sublimation of  $\text{WCl}_6$  is described. Nephelometric titration of purified  $\text{WCl}_6$  by  $\text{AgNO}_3$  gives, as the mean of 22 experiments, W  $183.92 \pm 0.014$  (Ag 107.880, Cl 35.457). F. L. U.

Double-focussing mass spectrograph and the masses of  $^{15}\text{N}$  and  $^{18}\text{O}$ . J. MATTAUCH (Physical Rev., 1936, [ii], 50, 617—623).—The theory and description of an instrument working as an "achromatic lens" for all masses are given. The differences of packing fraction of doublets containing  $^{15}\text{N}$  and  $^{18}\text{O}$  were determined. Isotopic wts. referred to  $^{16}\text{O} = 16$  are  $^{15}\text{N} = 15.0040 \pm 0.0008$ , and  $^{18}\text{O} = 18.0037 \pm 0.0007$ . N. M. B.

Evidence for the existence of an isotope of potassium of mass 40. A. O. NIER (Physical Rev., 1935, [ii], 48, 283—284).—The data obtained with a mass spectrograph of increased resolving power are considered to establish the existence of  $^{40}\text{K}$ . The abundance ratio  $^{39}\text{K} : ^{40}\text{K}$  is 8600 approx. L. S. T.

Further evidence for the existence of  $^{40}\text{K}$ . A. K. BREWER (Physical Rev., 1935, [ii], 48, 640).—Mass spectra of positive thermions emitted from various K sources confirm the existence of  $^{40}\text{K}$  (cf. preceding abstract). The  $^{39}\text{K} : ^{40}\text{K}$  abundance ratio calc. is  $8300 \pm 100$ . L. S. T.

Separation of mercury isotopes. K. ZUBER (Helv. phys. Acta, 1935, 8, 488—490; Chem. Zentr., 1936, i, 494).—The III and IV components of the 2537 Å. Hg line excite respectively the 200 and the 202 Hg isotopes. Irradiation of a Hg- $\text{O}_2$  mixture with either of these lines causes selective oxidation of one isotope. The method gave positive results. H. J. E.

Evidence against  $^5\text{He}$ . R. D'E. ATKINSON (Physical Rev., 1935, [ii], 48, 382).—Evidence against the view that  $^5\text{He}$  should be stable is discussed. L. S. T.

Self-excitation of Geiger-Müller counters. G. MEDICUS (Z. Physik, 1936, 103, 76—112).—Of two  $\text{H}_2$ -filled counter tubes with Cu cathodes, one exhibited self-excitation, probably due to  $\text{H}_2\text{O}$  adsorbed on the glass walls. The influence of light, temp., and the presence of Hg vapour on the no. and distribution of impulses recorded over a given time was investigated. H. C. G.

Range of  $\alpha$ -particles and chemical linking. M. FÖRSTER (Ann. Physik, 1936, [v], 27, 373—388).—

The stopping power of  $\text{H}_2\text{O}$  vapour for  $\alpha$ -particles has been found to be about 3% < that of the  $\text{H}_2\text{-O}_2$  mixture from which it was formed. O. D. S.

Separation of  $\beta$ - and  $\gamma$ -radiation of radioactive preparations. H. STAUB (Helv. phys. Acta, 1935, 8, 512—513; Chem. Zentr., 1936, i, 14).—The material is placed at one end of a solenoid, by means of which  $\beta$ -rays of uniform velocity are focussed at a point outside the solenoid, and shielded by a Pb cylinder from direct  $\gamma$ -radiation. J. S. A.

Cloud chamber experiments with  $\gamma$ - and  $\beta$ -rays in xenon and krypton. H. KLARMANN and W. BOTHE (Z. Physik, 1936, 101, 489—498). A. B. D. C.

Liberation of electrons from solids by hard  $\gamma$ -rays. T. G. KUJUMZELIS (Z. Physik, 1936, 102, 762—767).—Measurements were made of the nos. of electrons liberated from C, Al, Cu, Sn, and Pb in forward and backward directions by  $\gamma$ -rays with energies between  $2.6 \times 10^6$  and  $7.7 \times 10^6$  e.v. Results plotted against at. no. give characteristic curves which indicate a possible method for determining the energy of unknown  $\gamma$ -radiation. H. C. G.

Effect of a magnetic field on the visible light produced in liquids by  $\gamma$ -rays. P. A. TSCHERENKOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 413—416; cf. A., 1934, 938).—Vavilov's theory that " $\gamma$ -luminescence" is due to Compton electrons liberated by the primary photons is supported by the asymmetric distribution of intensity of this light in a 9500 gauss magnetic field. R. C. M.

Excitation of secondary  $\gamma$ -rays by  $\beta$ -rays. E. STAHEL and P. KIPFER (Helv. phys. Acta, 1935, 8, 508—511; Chem. Zentr., 1936, i, 10).—The intensity of the secondary  $\gamma$ -radiation excited in Pb by the primary  $\beta$ -radiation from U-X has the same intensity as the primary  $\gamma$ -radiation of U-X, and is shown by absorption measurements to consist of two (possibly three) components. J. S. A.

Energy differences on addition of neutrons. R. FLEISCHMANN (Z. Physik, 1936, 103, 113—124).—Quantum energies of  $\gamma$ -rays resulting from the bombardment of H, Al, Fe, Cu, Se, Ag, Cd, Sm, Gd, Hg, and Pb by slow neutrons have been measured by a coincidence method using two Geiger-Müller counters. Results plotted against at. no. show max. for Fe and flat min. for rare earths, and then a further rise. The min. corresponds with a max. in the effective cross-section for the addition of slow neutrons. Cd was shown to emit  $\gamma$ -rays. H. C. G.

Neutrons from different sources. R. LADENBURG, R. ROBERTS, and M. B. SAMPSON (Physical Rev., 1935, [ii], 48, 467).—A preliminary report of the yields of neutrons obtained from targets of D compounds, Be metal, and LiF bombarded by accelerated deuterons under various conditions. L. S. T.

Slow neutrons. W. M. BRUBAKER and T. W. BONNER (Physical Rev., 1935, [ii], 48, 470).—Measurements of the tracks of the short-range recoil protons which are projected by neutrons in the energy interval 0.03—0.6 m.e.v. indicate no anomalous absorption within this range. L. S. T.

**Scattering of neutrons in matter.** L. S. ORNSTEIN (Proc. K. Akad. Wetensch. Amsterdam, 1936, **39**, 810—812).—The statistics of the scattering of neutrons by protons and nuclei are discussed.

D. C. J.

**Absorption of slow neutrons in silver.** L. N. RIDENOUR and D. M. YOST (Physical Rev., 1935, [ii], **48**, 383—384).—Data for the absorption by Ag of slow neutrons from B+Rn and Be+Rn sources as measured by detectors of Ag, Cu, V as  $\text{NH}_4\text{VO}_3$ , Br as  $\text{NH}_4\text{Br}$ , and I as  $\text{CHI}_3$  are recorded and discussed.

L. S. T.

**Absorption of neutrons in silver, cadmium, and boron.** II. N. DOBROTIN (Compt. rend. Acad. Sci. U.R.S.S., 1936, **3**, 291—293; cf. this vol., 1314).—The absorption of neutrons (from Ra and Rn on Be) by B has been studied as a function of the thickness ( $l$ ) of paraffin used to slow down the neutrons; results are similar to those with Cd. Filtration through Cd reduces the coeff. of absorption of neutrons in Ag. The relations between the activities of the two Ag isotopes have been studied, using different filters and vals. of  $l$ ; half periods of 24 sec. and 2.33 min. have been obtained. The ratio of the activities depended very little on  $l$ .

R. S. B.

**Slowing down of neutrons by the nuclei of heavy elements.** P. I. LUKIRSKI and T. CAREVA (Compt. rend. Acad. Sci. U.R.S.S., 1936, **3**, 411—412; cf. A., 1935, 141; this vol., 132, 402).—Neutrons from a Rn+Be source are slowed down to thermal velocities when passing through an enclosing Pb sphere of 7.4 cm. diameter.

R. C. M.

**Coincidence experiments with neutrons and  $\gamma$ -rays of beryllium.** H. MAIER-LEIBNITZ (Z. Physik, 1936, **101**, 478—485).—Disintegration of Be with  $\alpha$ -rays gives coupled neutrons and  $\gamma$ -rays, and  $\gamma$ -ray quanta in pairs.

A. B. D. C.

**$\gamma$ -Rays from nitrogen bombarded with deuterons.** H. R. CRANE, L. A. DELSASSO, W. A. FOWLER, and C. C. LAURITSEN (Physical Rev., 1935, [ii], **48**, 100).—The energy spectrum of recoil electrons from N, as  $\text{NH}_4\text{Cl}$ , bombarded with deuterons at 900 kv. indicates that the principal  $\gamma$ -ray lines are 1.9, 3.1, 4.0, 5.3, and 7.0 m.e.v.

L. S. T.

**$\alpha$ -Radioactivity of argon formed by radio-chlorine.** W. F. LIBBY, M. D. PETERSON, and W. M. LATIMER (Physical Rev., 1935, [ii], **48**, 571—572).—Radio-Cl from Ag radiochloride gives active A which yields a radiation, probably an  $\alpha$ -particle, of approx.  $3.1 \pm 0.2$  mm. range in air. Probable reactions are  $^{38}\text{Cl} = ^{38}\text{Ar} + e^-$  and  $^{38}\text{Ar} = ^{34}\text{S} + \alpha$ ,  $^{38}\text{Cl}$  being formed by  $^{37}\text{Cl} + \frac{1}{2}n = ^{38}\text{Cl}$ .

L. S. T.

**$\beta$ -Ray spectra of radioactive manganese, arsenic, and indium.** M. V. BROWN and A. C. G. MITCHELL (Physical Rev., 1936, [ii], **50**, 593—598; cf. Gaertner, this vol., 918).—The  $\beta$ -ray spectra were obtained by measuring tracks produced in a cloud-chamber in a magnetic field. Mn and As spectra were resolved into two components, the end-points being: Mn, 1.2 and 2.9; As, 1.09 and 3.4 m.e.v. The end-point for In is 1.45 m.e.v.

N. M. B.

**$\gamma$ -Rays from boron bombarded with protons.** H. R. CRANE, L. A. DELSASSO, W. A. FOWLER, and

C. C. LAURITSEN (Physical Rev., 1935, [ii], **48**, 102—103).—Bombardment of B by protons gives a  $\gamma$ -radiation of intensity  $\ll$  than obtained with deuterons as projectiles. The energy spectrum of recoil electrons indicates  $\gamma$ -ray lines at 2.5, 4.2, 5.7, 7.5, 9.8, and 13 (?) m.e.v. The upper limit of the  $\gamma$ -ray spectrum is at 14.5 m.e.v. approx. The probable reaction is  $^{11}\text{B} + ^1\text{H} \rightarrow ^{12}\text{C}$ .

L. S. T.

**Heavy particle component of the cosmic radiation.** R. B. BRODE, H. G. MACPHERSON, and M. A. STARR (Physical Rev., 1936, [iii], **50**, 581—588).—Investigation with a large Wilson cloud-chamber showed, in 8500 pictures, about 80 heavy tracks, of which 21 were made by particles of about the ionisation of slow protons. About 1% of the sea-level cosmic ionisation is due directly to heavy particles.

N. M. B.

**Artificial transmutation of light elements bombarded by ions of hydrogen and heavy hydrogen.** I. B. ARAKATSU, K. KIMURA, and Y. UEMURA (Mem. Fac. Sci. Agric. Taihoku, 1936, **18**, 75—94).—With apparatus of the type used by Oliphant and Rutherford, the relative probability of two alternative types of disintegration of  $^6\text{Li}$  and of  $^{11}\text{B}$  was measured.

A. E. M.

**Temporary excess of 10% in the cosmic radiation.** J. CLAY, E. M. BRUNS, and J. T. WIERSMA (Proc. K. Akad. Wetensch. Amsterdam, 1936, **39**, 813—815).—A sudden temporary increase in cosmic-ray intensity is reported.

D. C. S.

**Cosmic-ray showers produced by electrons.** E. C. STEVENSON and J. C. STREET (Physical Rev., 1935, [ii], **48**, 464—465).—Photographs of showers produced by an electron and by a non-ionising ray are reproduced.

L. S. T.

**Heavy particles from lead.** J. C. STREET, E. G. SCHNEIDER, and E. C. STEVENSON (Physical Rev., 1935, [ii], **48**, 463).—Heavy particles from a Pb plate have been observed in cloud-chamber photographs of cosmic-ray showers.

L. S. T.

**Cosmic-ray measurements with a Wilson chamber on Jungfraujoch.** G. HERZOG and P. SCHERRER (Helv. phys. Acta, 1935, **8**, 514—515; Chem. Zentr., 1936, i, 279).

J. S. A.

**Apparatus for prolonged registration of intensity course of cosmic radiation.** P. SCHERRER, H. STAUB, and H. WAFFLER (Helv. phys. Acta, 1935, **8**, 516—517; Chem. Zentr., 1936, i, 279).

J. S. A.

**Energy distribution of cosmic rays.** A. LONG-ACRE (Physical Rev., 1936, [ii], **50**, 674).—Statistical variations in Anderson and Neddermeyer's data are discussed. Analysis indicates that a sample of 100 vertical cosmic rays will contain 37 negative and 63 positive rays, the latter containing 18 in a low, and 45 in a higher, energy distribution.

N. M. B.

**Residual current in ionisation-pressure chamber, and variation with pressure of ionisation due to cosmic rays.** W. MESSERSCHMIDT (Z. Physik, 1936, **103**, 18—26).—Ionisation due to  $\alpha$ -particles was eliminated by working at 10—25 atm. -Rays and cosmic rays show differences of ionisation between 0 and 25 atm.

A. E. M.

**Effect of paraffin and lead on the rate of production of very large cosmic-ray bursts.** D. HEYWORTH and R. D. BENNETT (Physical Rev., 1936, [ii], 50, 589—593; cf. Doan, this vol., 265).—Using an intensity meter, data are given for the effects, at sea level for bursts  $> 15 \times 10^6$  ion pairs, on the rate of production of bursts of different magnitudes of degree of shielding of the ionisation chamber, heavy building structure above the instrument, and Pb and paraffin placed immediately above the ionisation chamber. The effect of paraffin is much  $<$  that of Pb. N. M. B.

**Cosmic-ray bursts.** W. MESSERSCHMIDT (Z. Physik, 1936, 103, 27—56).—Collision distribution curves as regards size and frequency are given for Al, Fe, Pb, and C. A. E. M.

**Dependence of nuclear forces on velocity.** J. A. WHEELER (Physical Rev., 1936, [ii], 50, 643—649).—Mathematical. The Majorana force may be considered as a special case of a neutron-proton interaction dependent on velocity and angular momentum. The most general dependence of two-particle forces on spin, separation, and velocity, consistent with the conservation laws, is determined. N. M. B.

**Structure of atomic nuclei.** N. S. JAPOLSKY (Phil. Mag., 1936, [vii], 22, 537—581; cf. A., 1935, 1442).—Mathematical. The theory previously reported is developed and extended. N. M. B.

**Modification of the Moseley law.** V. DOLEJSEK (Acta phys. polon., 1934, 2, 439—446; Chem. Zentr., 1936, i, 503).—A general equation, valid for all the elements and all electron shells, is given. H. J. E.

**Must neutron-neutron forces exist in the  $^3\text{H}$  nucleus?** R. D. PRESENT (Physical Rev., 1936, [ii], 50, 635—642; cf. White, this vol., 400; Tuve, *ibid.*, 539).—Mathematical. Evidence points to the existence of direct like-particle forces in the nucleus. N. M. B.

**The neutron and structure of the atomic nucleus.** C. LOREY (J. pr. Chem., 1936, [ii], 147, 78—82).—Since, with the exception of  $^1\text{H}$ , all known isotopes have an at. wt.  $<$  double the nuclear charge ( $z$ ), it is suggested that each proton is associated with one neutron (neutron of the first kind). Since, however, most isotopes have an at. wt.  $> 2z$ , these must contain neutrons of the second kind, or "ballast neutrons." The nos. of protons and of neutrons of the two kinds are tabulated for a no. of isotopes. The no. of neutrons in the outermost quantum group of the at. nucleus has a bearing on the at. stability. J. W. S.

**Higher-order derivatives in the interaction "Ansatz" of the Fermi theory.** E. J. KONOPINSKI and G. E. UHLENBECK (Physical Rev., 1935, [ii], 48, 107—108; cf. A., 1935, 1048).—Mathematical. L. S. T.

**Recombination of neutrons and protons.** E. FERMI (Physical Rev., 1935, [ii], 48, 570).—Theoretical. L. S. T.

**Self-interaction of neutrons and protons.** D. IVANENKO and A. SOKOLOV (Nature, 1936, 138, 684).—The interaction between two heavy nuclear particles is computed on Fermi's theory, assuming

the interaction transfer by one pair and also by an arbitrary no. of pairs of electrons and neutrinos.

L. S. T.

**Relativity corrections in the theory of the deuteron.** E. FEENBERG (Physical Rev., 1936, [ii], 50, 674; cf. Margenau, this vol., 1175).—Mathematical. N. M. B.

**Comparison of Majorana-Heisenberg and velocity-dependent forces.** K. WAY and J. A. WHEELER (Physical Rev., 1936, [ii], 50, 675). N. M. B.

**Magnetic nuclear moment of platinum,  $^{195}\text{Pt}$ .** T. SCHMIDT (Z. Physik, 1936, 101, 486—488).—This moment is  $+0.6$  nuclear magneton. A. B. D. C.

**Quadrupole moment and magnetic moment of  $^{75}\text{As}$ .** H. SCHULER and M. MARKETU (Z. Physik, 1936, 102, 703—708).—From fine structure measurements, the quadrupole moment  $q$  is  $+0.3 \times 10^{-24}$  and the mean val. for the magnetic moment  $\mu$  is  $+1.5$  nuclear magnetons. L. G. G.

**Dissociative equilibrium and pair generation.** J. KISHEN (Indian J. Physics, 1936, 10, 389—397).—Mathematical. A general formula for the dissociative equilibrium in an external radiation field is developed and applied to thermal ionisation and to the formation and annihilation of pairs of electrons and positrons existing in statistical equilibrium with radiation. N. M. B.

**Self-consistent field, with exchange, for  $\text{Cl}^-$ .** D. R. HARTREE and W. HARTREE (Proc. Roy. Soc., 1936, A, 156, 45—62).—Fock's equations for the self-consistent field, with exchange, for the  $\text{Cl}^-$  ion have been solved, and the results are compared with those of the self-consistent field without exchange. The inclusion of exchange terms causes a contraction of the  $(3p)$  radial wave function. The effects of the inclusion on the X-ray scattering factor, the diamagnetic susceptibility, and the electrical polarisability are discussed. L. L. B.

**Fundamental frequencies and energy constants.** H. S. ALLEN (Proc. Roy. Soc., 1936, A, 156, 85—96).—The sp. heat of solids, energy, and optical data are considered. L. L. B.

**Fundamental physical constants.** W. N. BOND (Phil. Mag., 1936, [vii], 22, 624—632).—Estimates of numerical vals. of the consts. are deduced from Eddington's theories concerning  $M/m$ ,  $hc/2\pi e^2$ , and the universal gravitational const. Confirmatory experimental evidence is given, and the remaining discrepancies are pointed out. Full data and deductions are tabulated. N. M. B.

**Lorentz contraction of a liquid.** L. COURVOISIER (Z. Physik, 1936, 101, 422—436).—Observation of the Lorentz contraction through 1934 and 1935 showed a contraction of the correct frequency but of small amplitude. A. B. D. C.

**Lorentz contraction determined with levelled apparatus free to rotate.** L. COURVOISIER (Z. Physik, 1936, 101, 437—446).—Contractions observed agree with theory. A. B. D. C.

**Isotope relations in the spectra of  $\text{LiH}$  and  $\text{LiD}$ .** F. H. CRAWFORD and T. JORGENSEN, jun.

(Physical Rev., 1935, [ii], 48, 475; cf. A., 1935, 1051).

L. S. T.

**Spin coupling in  $^3\Sigma$  states of PH and PD.** M. ISHAQUE and R. W. B. PEARSE (Proc. Roy. Soc., 1936, A, 156, 221—232).—The spectrum of PD, like that of PH, consists of one intense band near  $\lambda$  3400 containing five max., which are more sharply defined in PD. The spin fine structure of the  $^3\Sigma$  states of PH and PD are compared with Kramers' formulæ and the consts.  $\epsilon$  and  $\gamma$  evaluated.  $\epsilon$  remains almost unchanged by the substitution of D for H, whilst  $\gamma$  is reduced to almost half.

L. L. B.

**Molecular spectra of magnesium deuteride.** Y. FUJIOKA and Y. TANAKA (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 30, 121—137).—Seven  $^2\Pi \rightarrow ^2\Sigma$  bands of MgD between 4900 and 5500 Å. have been analysed, and the mol. consts. evaluated.

J. S. A.

**Spectrum of indium oxide.** W. W. WATSON and A. SHAMON (Physical Rev., 1936, [ii], 50, 607—609; cf. Guernsey, A., 1934, 1055).—Wave no. data and assignments and intensities of the complex spectrum of InO lying between the two In resonance lines at 4102 and 4511 Å. are tabulated. An expression for the band heads is given.

N. M. B.

**New ultra-violet bands of  $\text{SO}_2$  in emission.** G. KORNFIELD (Trans. Faraday Soc., 1936, 32, 1487—1492).—59 bands between 2443 and 2123 Å., degraded to the red, are recorded in the spectrum of a blue electrodeless discharge in  $\text{SO}_2$ , 49 being known  $\text{SO}_2$  bands. None can be added to the known band system of  $\text{SO}$ . All the bands are attributed to  $\text{SO}_2$  in emission; a proposed classification is given.

A. J. E. W.

**Absorption spectrum of chlorine heptoxide.** C. F. GOODEVE and B. A. M. WINDSOR (Trans. Faraday Soc., 1936, 32, 1518—1519).—The spectrum consists of a single continuous band, setting in at about 3000 Å., and increasing in intensity to 2000 Å., the limit of observation. An extinction coeff. curve is given. Parallelism between the absorption spectra of Cl and N oxides is noted.

A. J. E. W.

**Ultra-violet absorption spectrum of hydrogen fluoride.** K. SIGA and H. J. PLUMLEY (Physical Rev., 1935, [ii], 48, 105).—With HF at 2 to 76 cm. pressure, band systems from 3200 to 2400 Å., with a max. at approx. 2800 Å., and from 2300 Å. to shorter  $\lambda\lambda$  have been found. The structure of both systems indicates that the absorbing mol. is a polymeride of HF.

L. S. T.

**Spectra of tellurium halides.** M. WEHRLI (Helv. phys. Acta, 1935, 8, 487—488; Chem. Zentr., 1936, i, 506).—The absorption bands of  $\text{TeCl}_2$  at  $\lambda\lambda$  6400—4700 Å. are diffuse. At 170° continuous absorption occurs at 2450 Å.  $\text{TeBr}_2$  has a similar band system at  $\lambda\lambda$  6500—5270 Å.

H. J. E.

**Band spectra of  $\text{MgCl}$ ,  $\text{MgBr}$ , and  $\text{MgI}$  in absorption.** F. MORGAN (Physical Rev., 1936, [ii], 50, 603—607).—Data, and analyses consistent with the respective isotope shifts, are recorded for single systems of four-headed bands in the range 3600—3950 for  $\text{MgCl}$  and 3800—4000 Å. for  $\text{MgBr}$ . All the bands degrade towards the violet. The analysis

of the  $\text{MgCl}$  system disagrees with that of Parker (cf. A., 1935, 562). A band system in the region 4040—4200 Å., degrading towards the violet, was observed for  $\text{MgI}$ .

N. M. B.

**Ultra-violet absorption spectra of  $\text{Pr}^+$  and  $\text{Nd}^{+++}$  ions in solution.** P. C. MUKHERJI (Indian J. Physics, 1936, 10, 319—323).— $\text{Pr}_2(\text{SO}_4)_3$  solution gave a broad diffuse band in the region 2750—2530 Å., resolving at increased dilution into components at 2730, 2605, and 2560 Å.  $\text{Nd}_2(\text{SO}_4)_3$  gave four new lines, 2775, 2730, 2600, and 2505 Å. The band 2280—2100 Å., reported by Freed (cf. A., 1932, 211), was not observed with  $\text{Nd}_2(\text{SO}_4)_3$  or  $\text{NdCl}_3$ . In  $\text{PrCl}_3$  and  $\text{NdCl}_3$  the bands are partly masked by continuous ultra-violet absorption.

N. M. B.

**Absorption spectrum of cobalt chloride in presence of magnesium chloride in aqueous solution.** O. R. HOWELL and A. JACKSON (J.C.S., 1936, 1268—1273).—Graphs show the absorption spectra of a series of solutions containing a fixed amount of  $\text{CoCl}_2$  with increasing concns. of  $\text{MgCl}_2$ . The extinction coeffs. at the max. of the chief bands, plotted against the concns. of  $\text{MgCl}_2$ , show that no blue constituent is formed until a crit. concn. of  $\text{MgCl}_2$  is reached; the amount of blue constituent then increases rapidly. The mechanism is similar to that caused by the addition of  $\text{HCl}$  to aq.  $\text{CoCl}_2$ .

W. R. A.

**Absorption spectra. I. (MILLER) C. L. HARBERTS, P. M. HEERTJES, L. J. N. VAN DER HULST, and H. I. WATERMAN (Bull. Soc. chim., 1936, [v], 3, 1916—1917; cf. this vol., 661).—A new method of calculating the mean absorption coeff. is developed and applied to the results reported previously.**

J. W. S.

**Spectrum of the cold flame of ether.** V. KONDRATEEV (Acta Physicochim. U.R.S.S., 1936, 4, 556—558).—The measurements by Emeleus of the bands in the spectrum of the cold flame of  $\text{Et}_2\text{O}$  (A., 1929, 1215) are similar to those by Herzberg and Franz of the fluorescence spectrum of  $\text{CH}_2\text{O}$  (A., 1932, 896). It is concluded that the emitters in the cold flame of  $\text{Et}_2\text{O}$  are  $\text{CH}_2\text{O}$  mols.

O. D. S.

**Absorption spectra of polyatomic molecules containing methyl and ethyl radicals. III.** H. W. THOMPSON and J. W. LINNETT (Proc. Roy. Soc., 1936, A, 150, 108—129; cf. A., 1934, 828; 1935, 1188).—All the mols. examined had all the linkings of a given element combined with an alkyl radical. Most of such compounds show continuous absorption in the region studied (2000—7000 Å.), but band systems, which have been analysed, are found for the Et derivative of Zn, Cd, and Hg, and for the thioethers. The photochemical significance of the continua is discussed.

L. L. B.

**Ultra-violet absorption spectrum of pyridine vapour. Relation to Raman spectrum.** V. HENRI and P. ANGENOT (J. Chim. phys., 1936, 33, 641—665).—The ultra-violet absorption spectrum of 0.01—910 mm. of  $\text{C}_5\text{H}_5\text{N}$  at 0—308° has been photographed. Fine bands extend from 3105 to 2750 Å. At shorter  $\lambda$ , the bands are broader and

absorption is continuous at  $< 2510 \text{ \AA}$ . Light of  $\lambda < 2750 \text{ \AA}$ . causes decomp. The bands of longer  $\lambda$  appear only as the temp. is raised, and correspond with higher vibration states of the normal mol. Analysis of the spectrum shows that the unexcited mol. has five fundamental frequencies: 600, 857, 993, 1031, and  $1159 \text{ cm}^{-1}$ , corresponding closely with the Raman spectrum vals., and, for each of the five series of bands, the normal frequency is 600 and that of the excited state,  $542 \text{ cm}^{-1}$ . The frequencies are assigned to appropriate vibrations of the mol. J. G. A. G.

**Optical absorption of porphyrins. VIII.** A. STERN and H. MOLVIG. **IX. Ultra-violet absorption. I.** F. PRUCKNER and A. STERN (Z. physikal. Chem., 1936, 177, 365—386, 387—397; cf. this vol., 1318).—VIII. Introduction of one or two  $\text{NO}_2$  into the aetioporphin mol. shifts the absorption max. towards the red, but the curve is still of the aetio type. Therefore the  $\text{NO}_2$  are not attached to a C of the methine bridge of the porphin system (I). If a Br is introduced into each of two adjacent nuclei in (I) the type of the absorption curve is unaltered, but if the substitution is in nuclei I and III the curve changes to the rhodo type, which supports the view that these nuclei have a pyrrolenine structure.  $\cdot\text{SO}_3\text{Me}$  influences the light absorption of (I) in the same way as a group containing CO, the absorption curves of these derivatives being of the rhodo type. The free porphinsulphonic acids apparently are inner salts, the  $\cdot\text{SO}_3\text{H}$  reacting with one of the N of nucleus III. Comparison of the absorption spectra of the Cu salts shows that the Cu in the phorbin (i.e., dihydroporphin) system (II) is bound in the same way as in (I), but by the action of secondary valencies between the C:N in (II) and the metal atom the chromophoric power of this group is intensified. The absorption curve of *Spirographis-haemin* (cf. *ibid.*, 1273) is of the rhodo type.

**IX.** In the ultra-violet down to  $240 \text{ m}\mu$  various normal porphyrins have only one absorption band, the mol. extinction coeff.,  $\epsilon$ , of which is high. The band is shifted appreciably only by the introduction into (I) of large chains or of groups containing CO. In the ultra-violet the absorption curve of porphin has a single band, and substitution even of alkyl groups only shifts the band max. and min. towards the red and depresses  $\epsilon$ . Monoimido- and  $\beta\delta$ -diimido-porphyrins have only one band, the max. of which is at a much shorter  $\lambda$  than that of the corresponding porphyrin. The absorption spectra of the octasubstituted porphins and phorbins have the same no. of bands, the red band of the porphin being much intensified and shifted towards longer  $\lambda\lambda$  in the phorbins. R. C.

**Ultra-violet absorption of phthiocol.**—See this vol., 1423.

**Infra-red absorption spectrum of heavy phosphine ( $\text{PD}_3$ ).** G. B. B. M. SUTHERLAND and G. K. T. CONN (Nature, 1936, 138, 641—642).—This spectrum agrees with the Raman spectrum but not with the frequencies predicted from the spectrum of  $\text{PH}_3$ , indicating that a simple valency force field

is not satisfactory for correlating the vibration frequencies of a mol. of this type. L. S. T.

**Rotation-vibration spectrum of acetylene ( $\text{C}_2\text{H}_2$ ).** R. MECKE and R. ZIEGLER (Z. Physik, 1936, 101, 405—417).—Eight new bands have been examined between 11,000 and 5700  $\text{\AA}$ ., and an analysis is given that accounts for 35 of the observed bands. A. B. D. C.

**Absorption spectra in the near infra-red of [saturated and] ethylenic hydrocarbons.** M. L. SHERRILL and P. MOLLET (J. Chim. phys., 1936, 33, 701—718).—The absorption spectra have been investigated at  $1.3\text{--}3.6 \mu$ , and absorption coeffs. are recorded. The substances conform to four types: (i)  $n\text{-C}_5\text{H}_{12}$ ,  $n\text{-C}_7\text{H}_{16}$ , (ii)  $\text{CH}_3\text{:CHPr}^a$ ,  $\text{CH}_3\text{:CH-C}_5\text{H}_{11}$ ,  $\text{CH}_3\text{:CHPr}^b$ ,  $\text{CH}_3\text{:CMeEt}$ , (iii)  $\text{CHMe:CHEt}$ ,  $(\text{CHEt})_2$ ,  $\text{CHEt:CHPr}^a$ , and (iv)  $\text{CHMe:CMe}_2$ ,  $\text{CHMe:CET}_2$ ,  $(\text{CMe}_2)_2$ , and all have strong absorption bands at  $7143\text{--}7246$ ,  $5715\text{--}5847$ ,  $4210\text{--}4264$ ,  $2906\text{--}2949$ , and  $2853\text{--}2877 \text{ cm}^{-1}$ . The  $2906\text{--}2949 \text{ cm}^{-1}$  bands of 'CRR' compounds are double, and compounds of type (ii) also have a strong band at  $3072\text{--}3091 \text{ cm}^{-1}$  which is attributed to C-H vibrations in the  $\text{:CH}_2$  group. The interpretation of the results is discussed. J. G. A. G.

**"Wing" accompanying the Rayleigh line in liquid mixtures. II.** S. C. SIRKAR and B. K. MOOKERJEE (Indian J. Physics, 1936, 10, 375—387; cf. this vol., 777, 923).—The distribution of intensity in the wing accompanying the Rayleigh line due to  $\text{CS}_2$ ,  $\text{CHCl}_3$ ,  $\text{PhCl}$ ,  $\text{COMe}_2$ , and xylene has been compared microphotometrically with that due to the solution of each in MeOH. The relative intensity of the wing with respect to that of any particular vibrational Raman line increases for solutions in MeOH, except in the case of  $\text{PhCl}$  where there is no appreciable change. In no case is there any marked diminution in intensity of any portion of the wing due to dissolution. Theoretical explanations are discussed. N. M. B.

**Polarisation of Raman lines in some inorganic acids.** C. S. VENKATESWARAN (Proc. Indian Acad. Sci., 1936, 4, A, 174—185).— $\text{HNO}_3$ ,  $\text{HIO}_3$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SeO}_4$ , and  $\text{H}_2\text{SeO}_3$  were investigated. The lines of conc.  $\text{HNO}_3$  showed depolarisations  $< 6/7$ . Polarisation of the lines due to  $\text{NO}_3'$  support the plane equilateral structure. Six lines of the undissociated  $\text{HNO}_3$  mol. were identified with those of an unsymmetrical pyramidal model.  $\text{H}_2\text{SO}_4$ ,  $\text{HSO}_4'$ ,  $\text{SO}_4''$ , and  $\text{H}_2\text{SeO}_3$  are tetrahedral and structural formulæ are discussed. Bands of  $\text{HIO}_3$  and  $\text{H}_2\text{SeO}_3$  are assigned to different mol. species. W. R. A.

**Raman effect of non-aqueous solutions of electrolytes. I. Solutions of arsenic halides.** V. FINKELSTEIN and P. KURNOSOVA (Acta Physicochim. U.R.S.S., 1936, 4, 123—134).—The Raman spectra of  $\text{AsCl}_3$  and  $\text{AsBr}_3$  in  $\text{Et}_2\text{O}$  and  $\text{C}_6\text{H}_6$  consist of the spectra of the pure solute and pure solvent only, indicating that the solvate is not a chemical compound. It is suggested that solvation occurs by dipole association. R. S.

**Raman spectra of trimethylamine and some compounds of hydroxylamine and hydrazine.**

R. ANANTHAKRISHNAN (Proc. Indian Acad. Sci., 1936, 4, A, 204—212).—The observed frequencies are discussed with the aid of polarisation data. A comparison with the spectrum of isobutane assists in the assignment of frequencies. The hydrochlorides of  $\text{NH}_2\text{OH}$  and  $\text{N}_2\text{H}_4$  in the cryst. state show a single line which remains strong in aq. solution. Possible structures are discussed. W. R. A.

**Raman effect of a complex tungstotartrate in water.** (Mlle.) M. THEODORESCO (Compt. rend., 1936, 203, 668—669).—The Raman spectra of aq. solutions of NaH tartrate (I),  $\text{Na}_2\text{WO}_4$  (II), and  $\text{Na}_2\text{T}_2\text{WO}_3$  (III) (T=tartrate) have been studied. Strong lines appear at 321, 832, and 934 (II), 837 and 943  $\text{cm}^{-1}$  (III). The lines 362, 837, 1088, and 1273 of (I) are not displaced in (III); the C=O line 1730 in (I) appears as 1606 and 1646 in (III); other lines of tartaric acid are displaced. The results favour the existence of (III) in solution. R. S. B.

**Raman spectrography and its importance in chemical investigations.** M. NORIEGA DEL AGUILA (Bol. Soc. Quim. Peru, 1936, 2, 86—125).—A review.

**Second-order lines in Raman spectra.** G. S. LANDSBERG and V. J. MALISHEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 365—368).—Six new lines were found in the Raman spectrum of  $\text{CCl}_4$  (529, 625, 919, 989, 1091, 1225  $\text{cm}^{-1}$ ) and nine new lines in that of  $\text{SnBr}_4$  (132, 144, 176, 193, 305, 370, 386, 438, 497  $\text{cm}^{-1}$ ). The frequencies, except 144, 386 of  $\text{SnBr}_4$ , are in agreement with calc. combination frequencies. The intensity of the second-order lines is approx.  $3 \times 10^{-3}$  that of the first order. O. D. S.

**Depolarisation of Raman lines of tetrachloroethylene.** T. Y. WU (J. Chinese Chem. Soc., 1936, 4, 402—405).—A discussion of the fundamental vibrations of the mol., based on the depolarisation measurements and the infra-red data (cf. A., 1934, 1288). D. C. J.

**Raman spectra. I. Benzoyl chloride and its substitution products.** D. D. THOMPSON and J. F. NORRIS (J. Amer. Chem. Soc., 1936, 58, 1953—1957).—Data are recorded for  $\text{BzCl}$  and for *o*-, *m*-, and *p*-methyl-, -methoxy-, -chloro-, and -nitrobenzoyl chloride. E. S. H.

**Structure by means of the Raman effect (2 phenylacetic acid-1 sodium phenylacetate) (2 acetic acid-1 sodium acetate).** E. VITALE (Gazzetta, 1936, 66, 566—570).—The Raman spectra of the compounds  $2\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{H}\cdot\text{CH}_2\text{Ph}\cdot\text{CO}_2\text{Na}$  and  $2\text{AcOH}\cdot\text{NaOAc}$  have been measured. In both spectra the line characteristic of the C=O group is missing. Structural formulæ are suggested. O. J. W.

**Raman spectra of *cis*- and *trans*-isoeugenol.** B. SUSZ and E. PERROTTET (Helv. Chim. Acta, 1936, 19, 1158—1163; cf. this vol., 923).—Data for the Raman spectra of purified commercial isoeugenol and for the *cis*- (I) and *trans*- (II) isomerides separated by fractional distillation are recorded and discussed. The frequency for the ethylenic linking is lowered by 25  $\text{cm}^{-1}$  in passing from (II) to (I), in conformity with observations on similar isomerides. F. L. U.

**Raman effect of organic substances. VI. Raman effect of sesquichamene and other terpenes.** K. MATSUNO and K. HAN (Bull. Chem. Soc. Japan, 1936, 11, 576—586).—Raman spectra of sesquichamene (I), *d*-sabinene, *d*- $\alpha$ -pinene, *d*-verbenol, *dl*- $\Delta^1$ -terpinen-4-ol, menthyl and isobornyl acetates have been studied. From a comparison of their spectra, it is thought that if cedrene has a 1-methyl- $\Delta^1$ -cyclopentene ring, (I) has a 1-methyl- $\Delta^1$ -cyclohexene ring. C. R. H.

**Raman spectrum and constitution of ozonides. Raman spectrum of ozonides of ethyl maleate and fumarate.** E. BRINER, E. PERROTTET, and B. SUSZ (Helv. Chim. Acta, 1936, 19, 1163—1168; cf. this vol., 839).—Data for the Raman spectra of  $\text{Et}_2$  maleate and fumarate and their ozonides are recorded and discussed. The mol. refractions observed are  $>$  those calc. by 4—5 units. F. L. U.

**Light-scattering of crystalline-liquid *p*-azoxyanisole.** W. DE BRAAF and L. S. ORNSTEIN (Kolloid-Beih., 1936, 44, 427—475).—The variation of scattering with the strength of a superimposed magnetic field has been determined. The results are in accordance with the swarm theory. E. S. H.

**Sensitisation of phosphors. II. S. ROTH-SCHILD (Physikal. Z., 1936, 37, 757—764; cf. A., 1934, 1056).—The sensitising effect of small amounts of Bi, Pb, Ag, Cu on Sm and Pr phosphors with CaS and SrS, and of Pr and Sm+Nd+Y on CaS-Ag and SrS-Ag phosphors has been investigated. Bi is effective in sensitising Sm but not Pr phosphors, Pb sensitises both, whilst Cu is ineffective in both cases. In most cases the sensitising effect is observable only during excitation. The theory is discussed. A. J. M.**

**Fluorescence of rare earths in glasses.** O. DEUTSCHBEIN (Z. Physik, 1936, 102, 772—780).—The fluorescence spectra of glasses activated with rare earths are generally similar to those of the corresponding rare-earth compounds. L. G. G.

**Influence of molecular rotations on measurements of the duration of fluorescence.** W. KESSEL (Z. Physik, 1936, 103, 125—132).—Jabłoński's theory of influence of mol. rotations has been tested by measurements with fluorescein in glycerol and  $\text{H}_2\text{O}$ . A. E. M.

**Quenching of fluorescence of dye solutions by foreign substances. I. B. SVESHNIKOV (Acta Physicochim. U.R.S.S., 1936, 4, 453—470).—The quenching of fluorescent dye solutions by inorg. and org. quenchers has been followed by observing the increase of polarisation. It is independent of the  $\lambda$  of the exciting light, confirming the view that in the excited state the mols. have the same energy level. Some quenchers exercise a selective action on some dyes. The results indicate that quenching action is produced by factors depending on time, and in many cases is due to deactivation through collisions of the second kind. C. R. H.**

**Quenching of fluorescence due to solution medium.** S. I. VAVILOV and A. N. SEVTSCH (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 277—284).—The intensity ( $\rho$ ) and degree of polarisation ( $p$ ) of fluor-

escence from rhodamine-*B* (I) have been studied in glycerol,  $\text{iso-C}_5\text{H}_{11}\cdot\text{OH}$ , and  $\text{Bu}^n\text{OH}$  at 289—363° abs.  $1/p$  is a linear function of  $T/\eta\rho_1$ , where  $T$  is the abs. temp.  $\eta$  the viscosity, and  $\rho_1$  is the val. of  $\rho$  at room temp.  $\tau_1$  and  $\rho$  have been determined for (I) in  $\text{H}_2\text{O}$  and org. solvents at room temp. Two types of quenching of fluorescence are discussed. R. S. B.

**Fluorescence intensity and duration.** S. I. VAVILOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 271—276).—The intensity ( $\rho$ ) and mean life of fluorescence phenomena are discussed. The relation  $\rho = s\tau/\tau_0$  is deduced, where  $s$  is the fraction of the absorbed energy which is quenched by collisions of the second kind,  $\tau$  the mean life of the excited state, and for  $s = 1$ . R. S. B.

**Photodissociation of gallium halides.** A. PETROVA (Acta Physicochim. U.R.S.S., 1936, 4, 559—566).—The first doublet, 4033 and 4172 Å., of the principal series of Ga is observed in the fluorescence excited in GaI vapour above 200° by  $\lambda\lambda < 2200$  Å. This fluorescence is ascribed to  $\text{GaI} + h\nu = \text{Ga}^+ + \text{I}$ . The fluorescence excited in GaBr vapour by  $\lambda\lambda > 1850$  Å. does not contain the resonance lines of Ga. O. D. S.

**Photo-electric phenomena at the surface of electronic semi-conductors.** G. LIANDRAT (Ann. Physique, 1936, [xi], 6, 391—454; cf. A., 1935, 1303).—On the basis of a crit. study of available experimental and theoretical data a simple description of the mechanism of the action of photo-elements is developed. The three essentials determining the direction and order of magnitude of the photo-electric effect are: in the cryst. lattice of a semi-conductor or insulator the photo-electrons traverse the surface with a kinetic energy, the max. val. of which satisfies the Einstein relation, they originate in the semi-conductor, and the high yield can be related to a sp. property of the lattice; in a metallic lattice they rapidly lose energy and become ordinary conductivity electrons; between the semi-conductor and the metal a thin cryst. layer of high resistivity controls the appearance of a p.d. Secondary modifications of the conductivity of the surface layer can be attributed to the ultimate behaviour of the electrons originating in the semi-conductor but stopped in the surface layer by the opposing electric field. N. M. B.

**Electrical investigation of oxidic semi-conductors.** W. HARTMANN (Z. Physik, 1936, 102, 709—733).—The variation of the electrical conductivity with temp. of  $\text{Al}_2\text{O}_3$ ,  $\text{Ta}_2\text{O}_5$ ,  $\text{UO}_2$ , and  $\text{CuO}$  is expressed by a simple exponential relation.  $\text{Al}_2\text{O}_3$  and  $\text{Ta}_2\text{O}_5$  showed changes of resistance after heating in vac., in  $\text{O}_2$ , or in  $\text{H}_2$ . The variation of the Hall const. with temp. of  $\text{UO}_2$  and  $\text{CuO}$  was also investigated. A. E. M.

**Electrical conductivity of thin metals, particularly of molybdenum layers.** J. H. DE BOER and H. H. KRAAK (Rec. trav. chim., 1936, 55, 941—953).—The conductivity of thin Mo layers deposited on glass increases with temp. in a reversible manner up to the temp. of deposition, above which there is an irreversible change to the properties of a layer deposited at the highest temp. attained. Unimol.

layers of Mo have appreciable conductivity, whereas a thickness of 16 mols. is required before that of Ag can be determined, owing to the difference in mol. mobility. The distribution of electron levels in a thin metallic layer, which is regarded as a state intermediate between vapour and massive solid, has been studied. R. S.

**Conductivity of copper oxide.** G. KAPP and M. TREU (Sitzungsber. physik.-med. Soz. Erlangen, 1935, 65—66, 215—228; Chem. Zentr., 1936, i, 285).—The electrical conductivity of thin CuO layers between 20° and —100° is recorded. J. S. A.

**Electrical energy set free on melting electrets.** H. FREI and G. GROETZINGER (Physikal. Z., 1936, 37, 720—724).—When an electret, with no electric field associated with it, is melted between two electrodes, a current flows, the total quantity of which is independent of the time which has elapsed between the polarisation and melting (depolarisation) of the electret. The current in the case of an electret which was formed by the action of an electric field on the substance in the solid state is much smaller. If a non-polar substance, such as paraffin, is submitted to the action of an electric field when it is solidifying, or when it is solid, the amount of electricity obtained on melting is the same in both cases. The results agree with the theory that a permanent electric polarisation independent of time has occurred in electrets. A. J. M.

**Variation of the dielectric constant of mercury with density at different temperatures.** P. WUSTHOFF (Ann. Physik, 1936, [v], 27, 312—328).—The dielectric const. of Hg vapour has been measured at several temp. between 401° and 470° and pressures up to 3 atm. No deviation from the Clausius-Mosotti relationship was observed. The dielectric const. of Hg at atm. pressure and 0° is calc. to be 1.00170. O. D. S.

**Dielectric coefficients of gases. III. Allene, allylene, butanes, butylenes, cyanogen, and hydrogen cyanide.** H. E. WATSON and K. L. RAMASWAMY. **IV. Fluorides of boron, nitrogen, and carbon.** H. E. WATSON, G. P. KANE, and K. L. RAMASWAMY (Proc. Roy. Soc., 1936, A, 156, 130—143; cf. A., 1934, 347).—The measurements were made by means of the "parallel condenser" method used previously. *n*- and *iso*- $\text{C}_4\text{H}_8$ , allene, allylene, and  $\text{NF}_3$  have small moments, and  $\text{HCN}$  a large one, whilst the remaining gases are electrically neutral. L. L. B.

**Electric moments of aliphatic diamines.** P. TRUNEL (Compt. rend., 1936, 203, 563—565).—Measurements were made in  $\text{C}_6\text{H}_6$  at 25°, 45° and 75°. The dipole moments at 25° are:  $(\text{CH}_2\cdot\text{NH}_2)_2$  1.90,  $\text{NH}_2\cdot[\text{CH}_2]_1\cdot\text{NH}_2$  1.94,  $\text{NH}_2\cdot[\text{CH}_2]_4\cdot\text{NH}_2$  1.93,  $\text{NH}_2\cdot[\text{CH}_2]_5\cdot\text{NH}_2$  1.91, and  $\text{NH}_2\cdot[\text{CH}_2]_6\cdot\text{NH}_2$  1.98 *D*, and the vals. are not affected significantly by the changes of temp. There is negligible interaction between the  $\cdot\text{NH}_2$  groups and their rotation is not restricted. J. G. A. G.

**Structure of coumarin.** M. A. G. RAU (Current Sci., 1936, 5, 132).—The dipole moment of coumarin

at 20° ( $4.51 \times 10^{-18}$  e.s.u.) indicates a state of resonance between the normal and an excited state.

F. N. W.

**Evidence of wave-mechanical resonance in the carboxylic ester and lactone group, from electric dipole moments.** R. J. B. MARSDEN and L. E. SUTTON (J.C.S., 1936, 1383—1390).—The calc. moments for the two extreme possible configurations of the CO<sub>2</sub>R group are given. From these vals. and the moment of  $\gamma$ -butyrolactone it is shown that the esters have the *trans* configuration. This cannot be due to electrostatic forces alone but to stiffening produced by resonance with another structure. The resonance interaction of phenolic and benzoic esters with the benzene ring supports the Robinson-Ingold theories. The configuration of nitrous esters is discussed.

W. R. A.

**Carbon valency angle and dipole induction in benzyl compounds.** F. C. FRANK (J.C.S., 1936, 1324—1327).—Solvent effects do not invalidate stereochemical calculations from dipole moment data. In considering benzyl compounds, it is assumed that, in compounds of the type CH<sub>2</sub>Ph·Y, the induced moment in the Ph due to the C·Y moment lies parallel to the Ph·C linking, and that, in compounds of the type C<sub>6</sub>H<sub>4</sub>X·CH<sub>2</sub>·Y, vector addition is permissible only if X and Y are each outside the sphere of induction of the other. Equations are given from which, by a graphical method, the induced moment along Ph·C and the C valency angle are obtained. The valency angle of aliphatic C is 110°.

W. R. A.

**Theory of polarisation of dipole moments.** J. FRENKEL (Acta Physicochim. U.R.S.S., 1936, 4, 341—356).—Expressions for the elastic (static) and frictional (kinetic) effects in the orientation of dipole mols. are derived mathematically and considered in relation to Debye's recent theories.

C. R. H.

**Dipole moments and the fixation of aromatic double linkings.** Bromohydrindenes and bromotetralins.—See this vol., 1497.

**Volume of an anisotropic liquid in a magnetic field.** D. BENESZEVICZ (Acta Physicochim. U.R.S.S., 1936, 4, 607—612).—No change in vol. is observed in the anisotropic phase of dibenzylidenebenzidine and *p*-azoxyanisole under the influence of magnetic fields from 3000 to 17,000 gauss.

O. D. S.

**Refractive index of deuterium.** W. J. C. ORR (Trans. Faraday Soc., 1936, 32, 1556—1559).—The difference in *n* of H<sub>2</sub> and D<sub>2</sub> has been measured. Assuming *n*=1.00013966 for H<sub>2</sub> at  $\lambda$  5462, *n* for D<sub>2</sub> is 1.0001378(7).

E. S. H.

**Refractive index, dispersion, and polarisation of gases.** H. E. WATSON and R. L. RAMASWAMY (Proc. Roy. Soc., 1936, A, 156, 144—157).—The refractions and dispersions of CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>, C<sub>3</sub>H<sub>8</sub>, *n*- and *iso*-C<sub>4</sub>H<sub>10</sub>, C<sub>2</sub>H<sub>4</sub>, C<sub>3</sub>H<sub>6</sub>, *n*-, *iso*-, and *sec*-C<sub>4</sub>H<sub>8</sub>, C(CH<sub>3</sub>)<sub>2</sub>, C<sub>2</sub>H<sub>2</sub>, CMe<sub>2</sub>CH, SiH<sub>4</sub>, Si<sub>2</sub>H<sub>6</sub>, HCN, (CN)<sub>2</sub>, BF<sub>3</sub>, NF<sub>3</sub>, CF<sub>4</sub>, SiF<sub>4</sub>, SF<sub>6</sub>, and CO<sub>2</sub> have been measured and the electronic polarisations calc. The vals. are compared with the polarisations deduced from dielectric measurements of the same samples of gas. The at. polarisations are obtained by deduction,

and vary from 0 for the rare gases and most bimol. gases to 70% of the electronic polarisation for (CN)<sub>2</sub>. For the aliphatic hydrocarbons, they follow the sequence acetylenes > olefines > paraffins, and increase with the size of the mol.

L. L. B.

**Streaming double refraction of high-molecular substances.** IV. Polystyrenes with different degrees of branching. R. SIGNER (Helv. Chim. Acta, 1936, 19, 897—899; cf. A., 1933, 902).—The fluxional birefringence of polystyrenes is the lower, the higher is the temp. at which polymerisation occurred. A similar relation holds with regard to the extinction angle. These observations support the conclusion of Staudinger and Schulz (this vol., 146) that the degree of branching increases with rise of the temp. of polymerisation.

F. L. U.

**[Optical] dispersion of natural and mercerised cellulose.** A. FREY-WYSSLING (Helv. Chim. Acta, 1936, 19, 900—914; cf. this vol., 140).—The *n* of fibres of ramie cellulose varies with the liquid in which they are immersed in consequence of adsorption, especially with glycerol and with CH<sub>2</sub>Ph·OH. The dispersion, *n<sub>D</sub>*—*n<sub>C</sub>*, is 0.0070—0.0077 both for natural (I) and mercerised (II) fibres. The *n<sub>D</sub>* vals. for (I) are >1.596 and 1.528 for the extraordinary and ordinary ray, respectively, the corresponding vals. for (II) being <1.574 and 1.525. The decrease in refraction on mercerisation is consistent with the resulting broadening of the cryst. lattice.

F. L. U.

**Optical rotatory dispersion in the glucal series.**—See this vol., 1363.

**Optical rotatory dispersion of bridged derivatives of alkyltartrates.** Y. TSUZUKI (Bull. Chem. Soc. Japan, 1936, 11, 586—592).—The rotatory dispersion between 6708 and 4358 Å. of Et<sub>2</sub> and Me<sub>2</sub> isopropylidenedioxysuccinate, Et<sub>2</sub> and Me<sub>2</sub> ethylidenedioxysuccinate, and Et<sub>2</sub> methylenedioxysuccinate (cf. A., 1935, 1106; this vol., 967) in the pure state has been measured. The vals. can be expressed by a one-term Drude equation, and this, together with the dispersion ratio and the characteristic  $\lambda$ , appears to indicate that the rotatory dispersion is simple.

C. R. H.

**Optical rotatory power of solutions in an electric field.** J. KUNZ and S. H. BABCOCK (Phil. Mag., 1936, [vii], 22, 616—624; cf. this vol., 13).—When various optically active menthyl compounds were subjected to an electric field no Kerr effect was observed, but the rotation of the plane of polarisation depended on the angle between that plane and the field, and was a function of the field strength quite different from the Kerr effect.

N. M. B.

**Magneto- and electro-optical properties of *p*-azoxyanisole.** (MRS.) J. Z. K. EISENMANN (Ann. Physique, 1936, [xi], 6, 455—501).—A detailed description and discussion of an investigation previously reported (cf. A., 1935, 568).

N. M. B.

**Magnetic birefringence in solutions of organic substances.** L. D. MAHAJAN (Phil. Mag., 1936, [vii], 22, 717—725).—Results are tabulated for the following substances, the solvent being shown in parentheses; *o*-, *m*-, and *p*-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub> (Et<sub>2</sub>O); phloro-

glucinol, durene, and  $C_6Me_6$  ( $COMe_2$ );  $C_6Et_6$  ( $CCl_4$ );  $C_6(HCl)_6$  ( $Et_2O$ );  $C_6Cl_6$  ( $CS_2$ ); *o*-toluidine ( $COMe_2$ ); *m*-nitroaniline ( $Et_2O$ ); *p*-benzoquinone, chloranil, and bromanil ( $COMe_2$ ); dimesityl ( $CCl_4$ ); diphenylene oxide ( $CCl_4$  and  $COMe_2$ );  $\alpha$ - $C_{10}H_7NH_2$ , and phenanthraquinone ( $COMe_2$ );  $\alpha$ -naphthaquinone and anthraquinone ( $CCl_4$ );  $C_6H_6$ . Results are discussed in relation to mol. structure and the influence of the structure on magnetic and optical anisotropy of the mols.  
N. M. B.

**Natural classification of chemical compounds.** F. M. SCHEMJAKIN (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 49—54).—Previous theories (A., 1935, 569) are developed.  
R. T.

**Valency problem of the quinquevalent phosphorus atom.**—See this vol., 1377.

**Constitution of phosphorous, hypophosphorous, and sulphurous acids.** G. SCHWARZENBACH (Helv. Chim. Acta, 1936, 19, 1043—1052; cf. this vol., 680).—From consideration of the several dissociation consts. of  $H_3PO_3$ ,  $H_3PO_2$ , and  $H_2SO_3$  it is concluded that  $H_3PO_3$  contains one, and  $H_3PO_2$  two H atoms linked directly to P, and that  $H_2SO_3$  has a symmetrical structure. These conclusions do not apply to their metal or alkyl derivatives. F. L. U.

**Maximum valency of elements and atomic structure.** VI. Quantum characteristics of valency electrons and the m.p. of simple substances. VII. Quantum characteristics of valency electrons and the structure and lattice strength of simple substances. B. ORMONT (Acta Physicochim. U.R.S.S., 1936, 4, 409—426, 427—440).—A discussion on the deviations from the Grimm-Sommerfeld law and on the quantum characteristics of valency electrons as revealed by a study of the m.p. and lattice structure of the elements (cf. A., 1935, 1058; this vol., 141).  
C. R. H.

**Interaction of atoms and molecules with solid surfaces.** III, IV. Condensation and evaporation of atoms and molecules. J. E. LENNARD-JONES and A. F. DEVONSHIRE. V. Diffraction and reflexion of molecular rays. A. F. DEVONSHIRE (Proc. Roy. Soc., 1936, A, 156, 16—28, 29—36, 37—44; cf. A., 1935, 1070).—III. Theoretical. Formulae have been found for the probability that an impinging particle will condense on to a solid surface, and for the length of time it will remain there. The theory thus provides explicit formulae for the consts.  $C$  and  $T$  of Langmuir's adsorption isotherm. Evaporation may, even at low temp., take place in two stages, an atom first being excited to a higher vibrational level and then receiving another quantum of thermal energy from the solid sufficient to cause evaporation. To illustrate the effect of mass, the probabilities of evaporation and condensation of the isotopic mols.  $H_2$ ,  $HD$ , and  $D_2$  have been calc. The coeff. of condensation is in some cases quite small (of the order of 0.1).

IV. A model is considered in which an adsorbed atom can vibrate both radially and laterally about its point of attachment, but cannot migrate. Evaporation is controlled by the rate at which thermal energy is communicated from the solid to the adsorbed atom.

V. The theory of the reflexion and diffraction of mol. rays from crystal surfaces is worked out. The minima found by Frisch and Stern in the reflexion and diffraction curves of He and Li (A., 1933, 994) are explained. The experimental curves may be used to give information about the potential field in the neighbourhood of the solid.  
L. L. B.

**Relation between the tension  $\tau$  of Baeyer and the characteristic Raman frequency for cyclic hydrocarbons.** M. AUBERT (Compt. rend., 1936, 203, 661—663).—Baeyer's tension  $\tau$  for a cyclic hydrocarbon with  $n$  C atoms, defined by  $\tau = 1/2[109^\circ 28' - 180^\circ(n-2)/n]$ , or  $\tau = (10800 - 2116n)/n$  in min., is related to the characteristic Raman frequency  $\nu$  according to  $\nu = 0.2266\tau + 868$  cm.<sup>-1</sup> for  $n=2-8$ , when there is no side-chain. The combination of the formulae for  $\nu$  and  $\tau$  gives  $(2447.3 + 388.5n)^2/n$  which gives a min. for  $n^2$  at  $n=6.29$ .  $n\nu^2$  is const. for vals. of  $n$  near to 6, as found by Godchot *et al.* (A., 1932, 213).  
R. S. B.

**Atomic and ionic radii.** II. E. HERLINGER (Z. Krist., 1936, 93, 399—408).—The radii of action of atoms and ions are compared, and the constancy of radius of ions not built on the pattern of the noble gases is derived.  
B. W. R.

**Relation between internuclear distances and the force constants of diatomic molecules.** R. M. BADGER (Physical Rev., 1935, [ii], 48, 284—285; cf. A., 1936, 14).  
L. S. T.

**Energy levels in crystals of samarium salts.** C. B. ELLIS (Physical Rev., 1936, [ii], 50, 675; cf. Spedding, A., 1934, 1154).—The more than fourfold increase in the no. of lines in a close group in Sm over the no. in similar groups of Gd is attributed to the coupling of a set of vibrational levels to the crystal field levels, and the presence of higher coupling frequencies different for each compound in addition to crystal field splitting.  
N. M. B.

**Theory of movable voids and inter-lattice atoms in crystals.** J. FRENKEL (Acta Physicochim. U.R.S.S., 1936, 4, 567—574).—The mechanism of void formation in crystals is discussed. The dependence of the no. of voids and of the no. of dissociated atoms in monat. crystals on temp. is calc. statistically. The result of a similar calculation for binary ionic crystals is in agreement with that of Schottky (A., 1935, 1302).  
O. D. S.

**Approximation method in the problem of many electrons.** II. H. HELLMANN (Acta Physicochim. U.R.S.S., 1936, 4, 225—244; cf. A., 1935, 278).—Mathematical. A wave-mechanical discussion is given.  
R. S. B.

**Solving variational problems in quantum chemistry.** A. SCHUCHOVITZKI (Acta Physicochim. U.R.S.S., 1936, 4, 803—818).—Theoretical.  
H. J. E.

**Quantisation of a theory arising from a variational principle for multiple integrals with application to Born's electrodynamics.** P. WEISS (Proc. Roy. Soc., 1936, A, 156, 192—220).—Mathematical.  
L. L. B.

**Spectroscopic investigation of molecular association.** M. V. VOLKENSTEIN (*Acta Physicochim. U.R.S.S.*, 1936, 4, 357—364).—The influence of mol. association on mol. symmetry as deduced from infra-red and Raman spectra is discussed. If the association forces are weak, corresponding with energies  $> 10$  kg.-cal. per mol., the mols. can be regarded as unassociated but having their symmetry distorted. If association energy approaches that of homo- or hetero-polar linking, the product is intermediate between a chemical compound and a van der Waals complex. The existence of a frequency band at  $622\text{ cm.}^{-1}$  in the Raman spectrum of AcOH and its weakening with dilution is attributed to the association of two AcOH mols. C. R. H.

**Parachors of some metal carbonyl compounds.** J. S. ANDERSON (*J.C.S.*, 1936, 1283—1286).—Surface tensions and parachors of  $\text{Ni(CO)}_4$ ,  $\text{Co(CO)}_3(\text{NO})$ ,  $\text{Fe(NO)}_2(\text{CO})_2$ , and  $\text{Fe(CO)}_5$  have been measured. As with other co-ordination compounds the apparent parachor of the central atom shows an anomaly for which no adequate explanation has so far been advanced. W. R. A.

**Combination of fatty acids with nitrogen bases. I. Piperidine and lower fatty acids: surface tensions, molecular volumes, and parachors.** E. B. R. PRIDEAUX and R. N. COLEMAN (*J.C.S.*, 1936, 1346—1353).—The salts formed by mixing piperidine with the lower fatty acids (acetic to octoic) have been prepared and examined. The effect of chemical combination on the densities of pairs of liquids having a similar polar constitution has been measured. Variations of surface tension with temp. have been determined. Salt formation is accompanied by considerable diminution of the parachors, although association also produces diminutions but of a much small order. W. R. A.

**Cleavage and X-ray planes of calcite crystals.** J. A. BEARDEN and H. H. ROSEBERRY (*Physical Rev.*, 1935, [ii], 48, 110).—In many cleaved calcite crystals which have good optical surfaces, the cleaved surface does not coincide with the at. or X-ray plane. The angle between the cleavage and X-ray planes is not the same for all crystals. L. S. T.

**Elimination of errors in Debye-Scherrer pictures—experiment or calculation?** A. LEVINŠ and M. STRAUMANIS (*Z. Krist.*, 1936, 94, 40—52).—An improved procedure for obtaining lattice consts. from powder photographs with max. accuracy is described, and illustrated from measurements on  $\text{TiCl}_3$ ,  $\text{As}_2\text{O}_3$ , and  $\text{Pb(NO}_3)_2$ . The Cohen formula is criticised. B. W. R.

**Calculation of the Laue patterns from plastically bent crystals of NaCl.** A. KOMAR (*Z. Krist.*, 1936, 94, 22—32).—A method of calculation of the Laue pattern for a bent rock-salt crystal is developed, with certain assumptions as to the behaviour of the slip planes. The calculation agrees quantitatively with experiment. B. W. R.

**Calculation of structure factors and summation of Fourier series in crystal analysis: non-centrosymmetrical projections.** J. M.

ROBERTSON (*Nature*, 1936, 138, 683—684).—A rapid numerical method is described. L. S. T.

**Interpretation of the powder radiograms of crystals by the method used for argillaceous mica slates.** J. DE LAPPARENT (*Compt. rend.*, 1936, 203, 596—599).—A discussion. H. J. E.

**Historical and systematic survey of the use of the "reciprocal lattice" in the study of crystal structure.** P. P. EWALD (*Z. Krist.*, 1936, 93, 396—398). B. W. R.

**Alteration in the axial ratio and in the position of the rhombic section with temperature of anorthite from Vesuvius.** H. SCHNAASE (*Z. Krist.*, 1936, 93, 444—463).—An anorthite crystal is measured goniometrically over the range room temp.— $973^\circ$ , and regular alterations in the fundamental symmetry angles are found. B. W. R.

**Physical properties of crystals.** A. GANGULI (*Current Sci.*, 1936, 5, 128—130).—A review.

**Theoretical basis for selection of optimum temperatures for monophasic metals. I. Recrystallisation diagrams.** A. A. BOTSCHVAR and G. G. PUTZIKIN (*Ann. Sect. d'Anal. Physico-Chim.*, 1936, 9, 153—158).—The process of recrystallisation of deformed metals is best represented by three-dimensional diagrams (crystal size-% deformation-temp.). R. T.

**Ring phenomenon in sputtered metallic films.** U. K. BOSE (*Nature*, 1936, 138, 684—685).—When cathodically sputtered on a clean glass plate Ag or Cu forms coloured rings surrounding a drop of oleic acid or a bead of plasticine placed on the plate. An explanation of the effect is discussed. L. S. T.

**Differences in lattice constants.** G. WASSERMANN (*Metallwirts.*, 1935, 14, 813—815; *Chem. Zentr.*, 1936, i, 22).—Differences between lattice consts. for single crystals and polycryst. materials (A., 1932, 330) may be attributed to impurities or to chilling stresses. J. S. A.

**X-Ray analysis in chemistry.** J. A. A. KETELAAR (*Chem. Weekblad*, 1936, 33, 648—654).—A review.

**Ideal and real crystals** (*Z. Krist.*, 1936, 93, 161—228).—A discussion of the papers on this subject (A., 1935, 16, 151). B. W. R.

**Etch-forms in glasses.** B. MARKIN, R. MULLER, and C. VEINSTEIN (*Acta Physicochim. U.R.S.S.*, 1936, 4, 119—122).—The etch-forms occur only when the glass surface has been in contact with a solid. The microscopic depressions so produced spread as the glass is uniformly dissolved, giving the characteristic honeycomb forms. K. S.

**Action of the electric field on the smectic meso-phase.** V. FREDERICKSZ and A. REPIEVA (*Acta Physicochim. U.R.S.S.*, 1936, 4, 91—98).—The production of focal-conical forms in the smectic meso-phase of Et *p*-azoxy-benzoate and -cinnamate has been studied. The elongated droplets produced near the temp. of transition to the amorphous liquid state orient themselves perpendicularly to weak electric fields, but turn through  $90^\circ$  when the field

strength is increased. With steadily increasing temp. and field strength the groups arrange themselves in regularly oriented series, and finally melt or explode to form the amorphous liquid. It is suggested that the orientation in weak electric fields is due to the orientation of dipoles, whilst in strong fields the effect of the induced polarisation is dominant. R. S.

**Elastic vibration of an anisotropic liquid.** V. ZOLINA (Acta Physicochim. U.R.S.S., 1936, 4, 85—90; cf. A., 1933, 1108).—Interference phenomena in anisotropic melts of Et *p-p'*-ethoxybenzylideneamino- $\alpha$ -methylcinnamate, acetoxybenzylideneazine, and dibenzylbenzidine, subject to tuning-fork vibrations, have been studied with the polarising microscope. R. S.

**Structure of crystalline bismuth and selenium layers produced by condensation in vacuum.** A. GOETZ and L. E. DODD (Physical Rev., 1935, [ii], 48, 165).—Similarities in the cryst. condensation of Bi and Se evaporated in a vac. are described. The cross-section in the direction of crystallisation of the condensed layers shows two distinct structures. The layer first deposited is microcryst. and  $10^{-2}$  cm. thick and then changes abruptly to a macrocryst. layer with fibrous texture. L. S. T.

**Relation between morphology and structure of potassium sulphate.** K. CHUDOBA and H. BEHNENBURG (Zentr. Min., 1935, A, 327—336; Chem. Zentr., 1936, i, 721). H. J. E.

**Arrangement of lattice blocks in the mosaic crystal, investigated with fused sodium nitrate crystals.** J. LEONHARDT and R. TREMEYER (Z. Physik, 1936, 102, 781—790).—The disposition of lattice blocks in a mosaic crystal is discussed from a consideration of X-ray interference patterns. A. E. M.

**Crystallography of magnesium, cobalt, and nickel sulphites.** H. A. KLASSENS, W. G. PERDOK, and P. TERPSTRA (Z. Krist., 1936, 94, 1—6).—Goniometric measurements, *d*, cell consts., and space-groups are given for  $\text{MgSO}_3 \cdot 6\text{H}_2\text{O}$  and the corresponding Co and Ni salts. Assuming that the six  $\text{H}_2\text{O}$  are symmetrically arranged around the metal ion, and the  $\text{SO}_3$  has a distinct entity, a possible structure is suggested which agrees with Zachariasen's theory of the pyramidal shape of the  $\text{SO}_3$ . B. W. R.

**Crystal lattices of heteropolyacids and their salts. II. Constitution of the silicotungstates of trivalent metals.** O. KRAUS (Z. Krist., 1936, 93, 379—395).—The higher hydrates of these salts have the general formula  $\text{M}^{III}\text{H}(\text{SiW}_{12}\text{O}_{40})_n \cdot n\text{H}_2\text{O}$ . Several new hydrates ( $\text{M}=\text{Fe}$  or  $\text{Cr}$ ) are described and their rotation photographs obtained. B. W. R.

**Lattice constants and space-group of lievrite.** P. KOKKOROS (Naturwiss., 1936, 24, 619).—Lievrite,  $[\text{CaFe}_2(\text{FeOH})(\text{SiO}_4)_2]$ , has *a* 8.76, *b* 13.04, *c* 5.82 Å., with 4 mols. in the unit cell. A. J. M.

**Alterations of the ionic distances in hydroxyl layer lattices.** W. LOTMAR and W. FEITKNECHT (Z. Krist., 1936, 93, 368—378).—From cell size measurements on mixed crystals of  $\text{Zn}(\text{OH})_2$  with Ni and Co hydroxides, an extrapolated val. for the non-

existent  $\text{Zn}(\text{OH})_2$  lattice of C6 type is deduced. Variations of the layer distance and alterations in the *a* axis and in the metal-OH distance, in the basic salts derived from this C6 lattice, are discussed. B. W. R.

**Lattice shrinkage and structure of montmorillonite.** G. NAGELSCHMIDT (Z. Krist., 1936, 93, 481—487).—This aluminosilicate shows a one-dimensional lattice shrinkage on drying. Measurements of the *d*(100) spacing are given over a range of 2—40 mols. of  $\text{H}_2\text{O}$  per unit cell; probably the first 4 mols. enter between the structure layers and thus alter *d*, while subsequent  $\text{H}_2\text{O}$  mols. remain at the crystal surface. B. W. R.

**Polyphosphonitrilic chloride, an inorganic "rubber."** K. H. MEYER, W. LOTMAR, and G. W. PANKOW (Helv. Chim. Acta, 1936, 19, 930—948; cf. this vol. 276).—X-Ray diagrams of unstretched polyphosphonitrilic chloride (I) are amorphous, but become cryst. on stretching. The unit cell contains 8  $\text{PNCl}_2$  groups and has *a* 11.07, *b* 4.92, *c* 12.72 Å. The space-group is probably  $C_{2v}^2$ . The P atoms (with attached Cl) are arranged in a zigzag chain with the N occupying intermediate positions. The dimensions of the crystallites are  $> 500$  Å. in every direction, corresponding with a mol. wt.  $< 20,000$ . Thermo-elastic measurements indicate that stretching is accompanied by progressive orientation of P-N linkings, the subsequent contraction being due to the tendency to disorientation. In details of behaviour (I) is closely analogous to rubber. F. L. U.

**Optical crystallographic data for some salts of the cinchona alkaloids.** M. L. SHANER and M. L. WILLARD (J. Amer. Chem. Soc., 1936, 58, 1977—1978).—Crystallographic data are recorded and the fluorescent properties in ultra-violet light described for quinine, quinidine, cinchonine, and cinchonidine. E. S. H.

**Crystallographic investigation of isomerides arising from the combination of *d*- and *l*-acids with *d*- and *l*-bases.** B. GOSSNER and H. NEFF (Z. Krist., 1936, 93, 488—493).—The four isomeric H tartrates of *d*- and *l*-ephedrine have been investigated by X-rays. B. W. R.

**Fine structure and transformations of alkali salts of long-chain fatty acids.** P. A. THIESSEN and J. STAUFF (Z. physikal. Chem., 1936, 177, 398).—Corrections to a previous paper (this vol., 1186). R. C.

**X-Ray investigation of the crystals of *p*-nitrodiphenyl.** M. PRASAD, M. P. LAKHANI, and J. SHANKER (J. Indian Chem. Soc., 1936, 13, 519—522).—The crystals belong to space-group  $Q^{13}$  with F0 Bravais lattice and the unit cell is asymmetric and contains 8 mols.; *a* 23.25, *b* 11.38, *c* 7.55 Å. The ratio *b*:*c* agrees with Groth and the ratio *a*:*b* is double. C. R. H.

**X-Ray measurements on diflavylene, rubrene, and related compounds.** W. H. TAYLOR (Z. Krist., 1936, 93, 151—155).—Diflavylene, monoclinic, has *a*<sub>1</sub> 6.7, *b*<sub>1</sub> 7.3, 16.7 Å.,  $\beta$ , 102°, 4 mols. in unit; space-group  $C_{2h}^2-P2_1/n$ . An alternative unit cell with *a*<sub>2</sub> 13.0, *b*<sub>2</sub> 7.3, *c*<sub>2</sub> 10.5 Å.,  $\beta$ <sub>2</sub> 90° contains

2 mols.; same space-group. The results indicate a *trans*-configuration for the mol. Rubrene *A* has  $a$  14.3,  $c$  7.0 Å.,  $\beta$  107°; rubrene *B* (distinguishable from *A* only by X-rays), monoclinic, has  $a$  17.9,  $b$ , 10.1,  $c$  8.8 Å.,  $\beta$  120°; 2 mols. in cell; space-group  $C_{2h}^2-P2_1/n$ . Didiphenylene-ethylene, orthorhombic, has  $a$  36.7,  $b$  34.3,  $c$  8.15 Å., 24 mols. in cell; space-group  $D_{2h}^2-Pmcb$  or  $C_{2h}^2-Pcb$ ; its 2:2'-F<sub>2</sub>-derivative,  $d$  1.357, is similar in structure. Some optical data are also given. B. W. R.

Crystal structure of condensed ring compounds. III. Three carcinogenic compounds: 1:2-benzpyrene, methylcholanthrene, and 5:6-cyclopenteno-1:2-benzanthracene. J. IBALL (Z. Krist., 1936, 94, 7-21).—1:2-Benzpyrene occurs in two modifications, (a) monoclinic, space-group  $C_{2h}^2$ ,  $a_0$  4.52,  $b_0$  20.32,  $c_0$  13.47 Å.,  $\beta$  97° 4', (b) orthorhombic, space-group  $C_{2h}^2$ ,  $a_0$  7.59,  $b_0$  7.69,  $c_0$  22.38 Å. The other two compounds are both monoclinic, space-group  $C_{2h}^2$ ,  $a_0$  4.86,  $b_0$  11.31,  $c_0$  27.7 Å.,  $\beta$  116° 5', and  $a_0$  12.02,  $b_0$  8.61,  $c_0$  13.78 Å.,  $\beta$  103° 0', respectively. Based on intensity measurements, probable mol. positions are given. A comparison is made with the structure of monoclinic 1:2:5:6-dibenzanthracene. B. W. R.

X-Ray crystallographic data on the sex hormones, oestrone, androsterone, testosterone, progesterone, and related substances. J. D. BERNAL and D. CROWFOOT (Z. Krist., 1936, 93, 464-480).—A summary of the data (chemical formula, cell size and structure, crystal habit, and general physical properties) now available for this group of substances. B. W. R.

X-Ray diffraction studies of chitin, chitosan, and derivatives. G. L. CLARK and A. F. SMITH (J. Physical Chem., 1936, 40, 863-879).—Natural chitin (I) shows preferred orientation of crystallites, with the  $b$  axis parallel to the surface in that produced in sheets, and to the axis of the fibre in tendons. After treatment with EtOH, fibres of (I) can be separated into uniform fibrils of diameter about 1  $\mu$ . On treatment with HCl at room temp. the ether linkages, and less rapidly the NH<sub>2</sub>-groups, of (I) are hydrolysed. At 200° (I) forms a definite additive compound with LiCNS, whilst at lower temp. intramolecular swelling occurs. Chitin nitrate is probably orthorhombic with  $a$  9.2,  $b$  10.3, and  $c$  23 Å., but fractions separated with different solvents show different average lengths of the C chain. The unit cell of chitosan is orthorhombic with  $a$  8.9,  $b$  10.25, and  $c$  17.0 Å. When formed from (I) in sheet form its (002) planes are parallel to the surface. Analyses show only about half the N required by Lowy's structure for chitosan, so it is suggested that there may be hydrolysis of the NH<sub>2</sub>-group. It is suggested that steric hindrance from another mol. causes only half the Ac groups to be hydrolysed in converting (I) into chitosan. J. W. S.

Fine structure of crystallised caoutchouc. W. LOTMAR and K. H. MEYER (Monatsh., 1936, 69, 115-124).—Redetermination of the consts. of the unit cell of cryst. (stretched) caoutchouc (cf. A., 1928, 1186) shows it to be monoclinic with  $a$  8.57  $\pm$  0.05,  $b$  8.20  $\pm$  0.05 (fibre axis),  $c$  12.65  $\pm$  0.05 Å.,  $\beta$  83° 20'.

The most probable space-group is  $C_{2h}^2$ . The crystallite is a mol. racemate of right- and left-handed spiral threads. F. L. U.

Origin of the "extra rings" in electron diffraction patterns. K. LARK-HOROVITZ, H. J. YEARIAN, and J. D. HOWE (Physical Rev., 1935, [ii], 48, 101).—The extra rings, similar to those reported for Au (A., 1931, 1206), obtained in the electron diffraction patterns of thin films of various metals deposited in a vac. on C<sub>10</sub>H<sub>8</sub>, are due to adsorbed layers of org. substances forming thin, cryst. layers and random oriented cross gratings. When NH<sub>4</sub>Cl replaces C<sub>10</sub>H<sub>8</sub> in the prep. of the films no extra rings appear in the diffraction patterns. L. S. T.

Surface of copper formed by solidification in a vacuum. S. DOBINSKI and C. F. ELAM (Nature, 1936, 138, 685).—X-Ray examination of Cu surfaces cryst. in a vac. showed that the orientation of the crystals differed from specimen to specimen, whilst electron diffraction showed spots from Cu crystals oriented with either {111} or {100} planes parallel to the surface, the {111} orientation being more frequent. L. S. T.

Molecular structures of the methyl derivatives of silicon, germanium, tin, lead, nitrogen, sulphur, and mercury, and the covalent radii of the non-metallic elements. L. O. BROCKWAY and H. O. JENKINS (J. Amer. Chem. Soc., 1936, 58, 2036-2044).—Electron diffraction investigations of gaseous SiMe<sub>4</sub>, GeMe<sub>4</sub>, SnMe<sub>4</sub>, PbMe<sub>4</sub>, NMe<sub>3</sub>, SMe<sub>2</sub>, and HgMe<sub>2</sub> yield the following vals. (in Å.) for interat. distances: Si-C 1.93  $\pm$  0.03, Ge-C 1.98  $\pm$  0.03, Sn-C 2.18  $\pm$  0.03, Pb-C 2.29  $\pm$  0.05, N-C 1.47  $\pm$  0.02, S-C 1.82  $\pm$  0.03, Hg-C 2.20  $\pm$  0.10. These vals. agree with published data for the sums of covalent radii. E. S. H.

Electron diffraction experiments on crystals of galena. L. H. GERMER (Physical Rev., 1936, [ii], 50, 659-671).—Electron diffraction patterns for cleaved, filed, and ground surfaces of galena crystals are photographed and described. The relation of results to the study of strain-hardening in metals is discussed. N. M. B.

Diffraction of electrons by molybdenite. G. I. FINCH and H. WILMAN (Trans. Faraday Soc., 1936, 32, 1539-1556).—Anomalous diffractions are explained in terms of the lattice limitation theory. Single crystals, only a few lattice layers thick, yield on rotation the two-dimensional cross-grating effect of continuous diffraction lines, which decrease in intensity with increasing crystal thickness. The axial ratio of molybdenite is 3.904;  $c$  appears to be independent of crystal thickness. The general theory of the loci of diffractions from rotating, undistorted and from stationary, curved molybdenite crystals is developed. E. S. H.

Electron diffraction by films built from many unimolecular layers. K. H. STORKS and L. H. GERMER (Physical Rev., 1936, [ii], 50, 676; cf. Holley, this vol., 539).—Patterns produced by films of multiple compressed layers of stearic acid and of mixed Ba and Cu stearates show symmetrical spot arrangements, proving that the mols. are regularly

arranged and that the crystal orientation is not random. The patterns differ entirely from those of a single stearic acid crystal obtained by evaporation from  $C_6H_6$  solution. N. M. B.

**Continuous magnetic spectrum at audio-frequencies of transformer lamina.** V. ARKADIEV (*Z. Physik*, 1936, 101, 527—532).

A. B. D. C.

**Gyromagnetic effect in pyrrhotine.** F. COETIERER (*Helv. phys. Acta*, 1935, 8, 522—564; *Chem. Zentr.*, 1936, i, 288).—The theory of the gyromagnetic effect is discussed. Measurements on pyrrhotine,  $Fe_nS_{n+1}$ , along the direction of easiest magnetisation, give  $g = 0.63$  as compared with  $g = 2$  for all other ferromagnetic substances, indicating that orbital momentum, and not only spin momentum, of the electrons is involved, in agreement with the strong magnetic anisotropy. J. S. A.

**Ferromagnetic phenomena.** J. L. SNOEK (*Nederl. Tijds. Natuurkunde*, 1935, 2, 180—189; *Chem. Zentr.*, 1936, i, 26—27).—In pure, unstrained material the crystal axes in Fe represent the directions of least, and in Ni the direction of greatest, energy. Fe-Ni alloys constitute a transition series, an alloy with 70% Ni being isotropic. Stress can produce an anisotropy. J. S. A.

**Physico-technical problems of ferromagnetism in weak fields.** R. GOLDSCHMIDT (*Helv. phys. Acta*, 1935, 8, 497—498; *Chem. Zentr.*, 1936, i, 287).—The loss angle is resolved into two components: one linearly  $\propto$  field strength and frequency, and one independent of field strength and frequency. The latter is investigated in a high-Si transformer sheet, and related to after-working effects. J. S. A.

**Magnetism and cold working in metals. II. Single crystals of bismuth, zinc, and tin.** S. R. RAO (*Proc. Indian Acad. Sci.*, 1936, 4, A, 186—203).—Single crystals of Bi, Zn, and Sn have been investigated for the influence of cold-work on the principal susceptibility. Bi showed a decrease, Zn showed a very small decrease in diamagnetic, and Sn in paramagnetic, susceptibility. The theory of Honda and Shimizu explains these changes. W. R. A.

**Effect of an external magnetic field on transition temperatures.** E. JUSTI (*Physikal. Z.*, 1936, 37, 766—768).—If the phases of a system of one component have different susceptibilities, the transition temp. of the phases are displaced by the application of a magnetic field. The displacement, which is very small, can be calc. from the change of susceptibility and entropy on transition. A. J. M.

**Heat effect of metallic transitions. IV. Nickel.** H. VON STEINWEHR and A. SCHULZE (*Physikal. Z.*, 1936, 37, 753—757).—The heat evolved in the magnetic transition of Ni (99.1%) is  $0.65 \pm 0.06$  g.-cal per g. The transition takes place over the range 333—362°. There was a small heat evolution at a temp. approx. 100° below the Curie point. A. J. M.

**Electrical anisotropy of single tungsten crystals at low temperatures in strong transverse magnetic fields.** E. JUSTI and H. SCHEF-

FERS (*Physikal. Z.*, 1936, 37, 700—708).—The resistance of W crystals at temp.  $< 20.38^\circ$  abs. is about 0.001 of that at  $0^\circ$ . On application of a transverse magnetic field (20,000 gauss) the resistance increases to its normal val. At low temp. the resistance is anisotropic, and the val. depends on the direction of the magnetic field. When the latter is perpendicular to a principal crystal plane, there is a smaller increase of resistance on applying the field, the increase being smallest for the [100] direction. Space-centred crystals of W show only half the no. of max. and min. in resistance shown by a face-centred crystal such as Au. At temp.  $< \text{b.p. of } H_2$  the resistance increases on application of the field approx. with the square of the field strength. The curve between field strength and increase of resistance varies by a const. factor as the crystal is rotated. A. J. M.

**Anode-sputtering and the deposition of metallic film on the cathode of a Hadding X-ray tube.** S. SHARAN (*Indian J. Physics*, 1936, 10, 325—340).—The structure of the deposits and application to anode sputtering are discussed.

N. M. B.

**Cathodic sputtering.** H. DAMIANOVICH (*An. Inst. Invest. cient. tecn.*, 1934, No. 3/4, 23—31; *Chem. Zentr.*, 1936, i, 497; cf. A., 1935, 1060).—The  $d$  of the product obtained in He corresponds with that calc. for  $Pt_5He$ . H. J. E.

**Rate of polymorphic transformations. IV. Influence of mechanical deformation on rate of transformation of polymorphic metals. II. Influence of admixed metals.** E. COHEN and A. K. W. A. VAN LIESHOUT (*Z. physikal. Chem.*, 1936, 177, 331—336; cf. A., 1935, 918).—The rate of transformation of white into grey Sn is much accelerated by small amounts of Zn (max. effect with 0.05%) and Al and retarded by Pb, Sb, Bi, Cd, and Ag. R. C.

**Molecular magnitude of metaphosphates.** P. NYLEN (*Z. anorg. Chem.*, 1936, 229, 30—35).—Cryoscopic measurements, by Richards' method, with a  $(NaPO_3)_x$  prep. described in the literature as monomeric, give  $x=2-3$ . Similar measurements with salts reported as tri- and tetra-meric, respectively, have confirmed the reports. F. L. U.

**Molecular size distribution in linear condensation polymerides.** P. J. FLORY (*J. Amer. Chem. Soc.*, 1936, 58, 1877—1885; cf. this vol., 295).—Size distributions of linear condensation polymerides are calc. on a wt. fraction and a mol. fraction basis, and on the assumption that the reactivity of functional groups is independent of the size of the mols. to which they are attached. The form of the distribution curves is not greatly changed when one of the reactants is in excess. Relations between "no.-average" ( $M_n$ ), "wt.-average" ( $M_w$ ), and "Z-average" mol. wts. are deduced in terms of  $p$ , the fraction of the total no. of functional groups which have reacted. Staudinger's viscosity term is not  $KM_n$ , but  $0.5KM_w$ , where  $M_w=(1+p)M_n$ . The original equation is valid only for polymerides of high mol. wt., i.e., for high vals. of  $p$ . F. L. U.

**Magnetic susceptibility of molecular hydrogen.** E. E. WITMER (Physical Rev., 1935, [ii], 48, 380).—A summary of calc. results not yet completed.

L. S. T.

**Magnetic susceptibility of mixed oxides of the rare earths. II. Samarium-gadolinium mixtures.** L. MAZZA and E. BOTTI (Gazzetta, 1936, 66, 552—562; cf. this vol., 19).—For  $\text{Sm}_2\text{O}_3$   $\chi=6.00 \times 10^{-6}$ , for  $\text{Gd}_2\text{O}_3$   $\chi=139.2 \times 10^{-6}$ . Mixtures of the two oxides do not obey Urbain's additive law. The results do not indicate the existence of any lower oxides, and give a single magnetic moment for  $\text{Gd}^{+++}$  of 39 Weiss magnetons. This agrees with the val. obtained from the susceptibility of  $\text{Gd}_2(\text{SO}_4)_3 \cdot 8\text{H}_2\text{O}$ , for which fresh measurements are recorded.

O. J. W.

**Magnetochemical investigation of metal ketyls of 4-pyrones.**—See this vol., 1396.

**Diamagnetism and particle size.** H. LESSHEIM (Current Sci., 1936, 5, 119—127).—A review.

**Cavitation caused by ultrasonic waves.** K. SOLLNER (Trans. Faraday Soc., 1936, 32, 1537—1539).—Cavitation can be made visible by irradiating with high energy long columns of de-gassed liquids.

E. S. H.

**Velocity of ultrasonic waves in heavy water.** R. BAR (Helv. phys. Acta, 1935, 8, 500—502; Chem. Zentr., 1936, i, 708).—The velocity in 99.2%  $\text{D}_2\text{O}$  at 20° was  $1.381 \times 10^5$  cm. per sec. The adiabatic compressibility of  $\text{D}_2\text{O}$  was  $4.733 \times 10^{-11}$  sq. cm. per dyne. The val. for  $\text{H}_2\text{O}$  is  $4.5477 \times 10^{-11}$  sq. cm. per dyne.

H. J. E.

**Visibility of ultrasonic waves in liquids.** S. PARTHASARATHY (Current Sci., 1936, 5, 136).—Parallel monochromatic light falls on one face of a cell containing a liquid through which ultrasonic waves are passing. Through the opposite face a microscope is focussed on the optical grating formed by the sound waves.

C. W. G.

**Ultrasonic velocities in organic liquids. VI. Related compounds.** S. PARTHASARATHY (Proc. Indian Acad. Sci., 1936, 4, A, 213—215; cf. this vol., 1189).—Diffraction of light by high-frequency sound waves is used to determine the acoustic velocity in four esters, three nitro-compounds, two aldehydes, in thyme oil, and in oil of turpentine. Adiabatic compressibilities are recorded.

W. R. A.

**Absorption of ultrasonic waves in acetic acid [and benzene and toluene].** P. BASHULIN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 285—288).—The absorption coeff. ( $\alpha$ ) of ultrasonic waves has been determined in  $\text{AcOH}$  at 17.5—28° for frequencies ( $\nu$ )  $(3.73-31.3) \times 10^6$ .  $\alpha$  is an approx. linear function of  $\nu$ .  $\alpha$  has been determined in 0—100% mixtures of  $\text{PhMe}$  and  $\text{C}_6\text{H}_6$  at 18° and  $\nu=11.47 \times 10^6$ . The difference in  $\alpha$  for  $\text{PhMe}$  and  $\text{C}_6\text{H}_6$  is that in  $d$ ,  $\eta$ , and velocity of propagation of sound.  $\alpha$  departs considerably from the additive law.

R. S. B.

**Dispersion of sound in liquids.** E. HIEDEMANN, N. SEIFEN, and E. SCHREUER (Naturwiss., 1936, 24, 681).—The dispersion of ultrasonic waves in  $\text{PhMe}$ , xylene,  $\text{NH}_2\text{Ph}$ , and  $\text{PhNO}_2$ , but not in

$\text{H}_2\text{O}$ , has been demonstrated, and its extent determined.

A. J. M.

**Entropy of deuterium oxide and the third law of thermodynamics.** Heat capacity of deuterium oxide from 15° to 298° abs. M.p. and heat of fusion. E. A. LONG and J. D. KEMP (J. Amer. Chem. Soc., 1936, 58, 1829—1834).—Heat capacity data are recorded and the entropy deduced.  $\text{D}_2\text{O}$  has m.p.  $276.92 \pm 0.05^\circ$  abs., and heat of fusion 1501 g.-cal. per mol.

E. S. H.

**Exact measurement of the specific heats of metals at high temperatures. XXV. Specific heats and the allotropy of nickel between 0° and 1000°.** M. EWERT (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 833—838).—A rapid increase of  $c_p$  with temp. occurs up to 345° for  $\alpha$ -Ni (cubic, ferromagnetic). The field of stable existence of the  $\alpha'$  form (hexagonal) is between 345° and 351°. From 351° upwards a much less rapid increase of  $c_p$  with temp. occurs for the  $\beta$  form. The heat effects of transition are approx.:  $\alpha \rightleftharpoons \alpha'$ , at 345°, 0.08 g.-cal.;  $\alpha' \rightleftharpoons \beta$ , at 351°, 0.31 g.-cal.

D. C. J.

**Determination of the true specific heats of silver, nickel,  $\beta$ -brass, quartz crystal, and quartz glass between 50° and 700° by an improved method.** H. MOSER (Physikal. Z., 1936, 37, 737—753).—The apparatus employed consisted of a Ag calorimeter in an atm. of A at low pressure.  $c_p$  of Ag was found to vary little with temp. The anomalies in  $c_p$  of Ni,  $\beta$ -brass, and quartz crystal extend over a wide temp. range, and begin about 300° < the accepted transition temp. at which  $c_p$  is a max. The return to the normal val. takes place over a very narrow temp. range in the case of quartz crystal. For the  $\alpha$ - $\beta$  transition of quartz, associated with a lattice change from the trigonal to the hexagonal, the abnormal increase in  $c_p$  before the transition can be explained as due to an expansion of the lattice, since  $c_p$  (cryst.)— $c_p$  (glass) =  $\Delta c_p$  is approx. equal to the val. calc. from the coeffs. of cubic expansion and compressibility.

A. J. M.

**Heats of crystallisation of methyl and ethyl esters of monobasic fatty acids.** (Miss) A. M. KING and W. E. GARNER (J.C.S., 1936, 1372—1376).—The sp. heats and heats of crystallisation of several Me and Et esters of long-chain (straight) fatty acids ( $\text{C}_{16}$ — $\text{C}_{22}$ ) have been determined. Two equations are derived connecting the m.p. with the no. of C in the chain, one for the Me esters of the even series, the other for the Et esters of the odd series.

W. R. A.

**Rare earth halides. X. M.p., particularly of the bromides.** G. JANTSCH and K. WEIN (Monatsh., 1936, 69, 161—166; cf. A., 1932, 1194; 1934, 157).—Previous work has been amplified by the determination of the m.p. of  $\text{LaBr}_3$ ,  $\text{CeBr}_3$ ,  $\text{PrBr}_3$ ,  $\text{NdBr}_3$ , and  $\text{SmBr}_3$ , which are respectively  $783 \pm 3^\circ$ ,  $732 \pm 2^\circ$ ,  $693 \pm 2^\circ$ ,  $684 \pm 2^\circ$ , and  $664 \pm 2^\circ$ . The relationship between the m.p. of various halides is discussed.

F. L. U.

**M.p. of long-chain carbon compounds.** (Miss) A. M. KING and W. E. GARNER (J.C.S., 1936, 1368—1372).—The heat increments and entropy

increments per  $\text{CH}_2$  are const. for homologous series with  $>10$  C in the chain. Differences in the physical properties of polymorphic modifications of long-chain compounds with vertical and tilted chains are given; for compounds with very long chains vertical chains are more stable than tilted chains at the m.p.

W. R. A.

Position of  $\lambda$ -points of helium. J. J. VAN LAAR (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 822—823).—A correction of the val. quoted in former paper (this vol. 787).

D. C. J.

Optical experiments on liquid helium II. L. V. SCHUBNIKOV and A. K. KIKOIN (Nature, 1936, 138, 641).—No evidence of the formation of liquid crystals could be obtained in liquid He between  $4.22^\circ$  and  $1.72^\circ$  abs. Hence, the anomaly in the sp. heat of liquid He at  $2.19^\circ$  abs. cannot be ascribed to a transition to the liquid crystal state.

L. S. T.

Vapour pressure and heat of sublimation of carbon. P. GOLDFINGER and W. JEUNEHOMME (Trans. Faraday Soc., 1936, 32, 1591—1598).—V.-p. curves have been deduced from published data for the heat of vaporisation of C. The most probable val. for the heat of vaporisation is  $123.6 \pm 0.5$  kg.-cal.

E. S. H.

Density of saturated vapours. M. F. SOONAWALA (Indian J. Physics, 1936, 10, 353—363).—Mathematical. The surface of a liquid is treated as a potential barrier, and the probability of transition across it of a mol. is obtained by wave mechanics. Application to experimental data shows that a mol. in a liquid has potential as well as kinetic energy. The val. of this potential energy is calc. for 13 liquids.

N. M. B.

Single linking energies. IV. V.-p. of hexaphenylethane. G. R. CUTHBERTSON and H. E. BENT (J. Amer. Chem. Soc., 1936, 58, 2000—2003; cf. this vol., 291).—For  $\text{CHPh}_3$  ( $26.5$ — $90.5^\circ$ )  $\log p = -5260/T + 12.72$ ,  $\Delta H = 24.1 \pm 1.0$  kg.-cal.; for  $\text{C}_2\text{Ph}_6$  ( $75.4$ — $120.8^\circ$ )  $\log p = -5987/T + 12.85$ ,  $\Delta H = 27.4 \pm 1.5$  kg.-cal.; for  $\text{CPh}_3$  peroxide ( $119.8$ — $161.0^\circ$ )  $\log p = -8259/T + 16.98$ ,  $\Delta H = 37.8 \pm 1.5$  kg.-cal. The heat of vaporisation shows that the C-C linking in  $\text{C}_2\text{Ph}_6$  vapour is weaker than the normal C-C linking.

E. S. H.

Vapour density of hexaphenylethane. H. E. BENT and E. S. EBERS (J. Amer. Chem. Soc., 1936, 58, 2073—2074).—Rapid decomp. prevents determination.

E. S. H.

U-Effect of Amagat and Weiss. Equation of state on the basis of selection theorems and the Joule-Thomson effect. II. V. JACYNA (Z. Physik, 1936, 103, 67—75).—Mathematical. The theoretical basis for the behaviour of gases at high pressures is reviewed.

H. C. G.

Compensation state ("basis line") for helium and carbon dioxide. I. V. JACYNA (Z. Physik, 1936, 103, 61—66).—Mathematical. A new equation of state having the parabolic form of the van der Waals-Berthelot equation is obtained and discussed in relation to available data for He and  $\text{CO}_2$ . The significance of the basis line is pointed out.

H. C. G.

X-Ray determination of the thermal expansion coefficients of beryllium and tin. G. F. KOSLOPOV and A. K. TRAPESNIKOV (Z. Krist., 1936, 94, 53—59).—The coeffs. are measured parallel and perpendicular to the  $a$  axis, using a back-reflexion camera, over the range  $18$ — $454^\circ$  for Be and  $23$ — $150^\circ$  for Sn, and are compared with previous results by the macroscopic method.

B. W. R.

Viscosity of air and electronic charge. V. D. MAJUMDAR and M. B. VAJIFDAR (Current Sci., 1936, 5, 133).—The method involves flow of air through a capillary tube.  $\eta = 1816.2 \times 10^{-7}$  c.g.s. unit at  $20^\circ$ ;  $e = 4.8022 \times 10^{-10}$  e.s.u.

C. W. G.

Influence of magnetic field on the coefficient of viscosity of liquids. II. S. D. CHATTERJEE (Indian J. Physics, 1936, 10, 399—401; cf. A., 1935, 1198).—Results are given for three non-polar liquids ( $\text{C}_6\text{H}_6$ ,  $p$ -xylene, and hexane) and for 9 monohydric alcohols. The former group shows a change of  $\eta$  in a magnetic field; in the latter the change seems to depend on the shape of the mol., the presence of a straight or a side chain, or general symmetry. The abs. change  $d\eta$  is given for 8 liquids for which  $\eta$  is altered by the magnetic field.

N. M. B.

Viscosity nomographs for alkaline solutions. D. S. DAVIS (Ind. Eng. Chem., 1936, 28, 953—956).—Nomographs for obtaining the  $\eta$  of aq. solutions of  $\text{NaOH}$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{KOH}$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{NaOH} + \text{Na}_2\text{CO}_3$ , and  $\text{KOH} + \text{K}_2\text{CO}_3$  at  $20$ — $40^\circ$  are given.

D. K. M.

[Temperature of vapour from boiling solutions.] K. SCHREBER (Z. ges. Kalte-Ind., 1935, 42, 131—135; Chem. Zentr., 1936, i, 604).—A discussion.

H. J. E.

Refractometry of binary liquid systems. III. V. J. ANOSOV (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 255—270).—A classification of the refractometric isotherms is proposed.

R. T.

Periodic variations of labile [alcohol-water] molecular complexes and their equilibrium position. L. SPLATT (Acta phys. polon., 1934, 2, 459—464; Chem. Zentr., 1936, i, 507).—Recorded observations of periodic variations in the longitudinal light scattering effect of  $\text{EtOH}$ — $\text{H}_2\text{O}$  mixtures are confirmed (cf. A., 1931, 900).

H. J. E.

Complex formation between polynitro-compounds and aromatic hydrocarbons. III. Systems containing tetranitromethane. D. L. HAMMICK and R. P. YOUNG (J.C.S., 1936, 1463—1467; cf. this vol., 722).—The formation of coloured complexes has been studied by determination of the colour density,  $D$ , at  $\lambda$  4300 Å. There is a linear relationship between  $D$  and the hydrocarbon (or substituted hydrocarbon) concn.  $b$  for  $\text{C}_6\text{H}_6$ ,  $\text{PhMe}$ ,  $o$ -,  $m$ -, and  $p$ -xylene,  $\text{PhOEt}$ ,  $\text{C}_{10}\text{H}_8$ ,  $2\text{-C}_{10}\text{H}_7\text{Me}$ ,  $2\text{:}4\text{-C}_{10}\text{H}_6\text{Me}_2$ ,  $\beta\text{-C}_{10}\text{H}_7\text{OH}$ ,  $1\text{-C}_{10}\text{H}_7\text{NO}_2$ , and anthracene, whilst in the case of mesitylene,  $D/b$  decreases as  $b$  increases. Relative vals. of the equilibrium consts. and heats of interaction have been calc.

R. S.

Thermal examination of chemical compounds in the system zinc-magnesium. M. I. ZACHAROVA and A. B. MLODZIEJEWSKI (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 193—202).—1:1 Mg-Zn alloys consist of a mixture of  $\text{MgZn}_2$ , eutectic, and

MgZn; after heating at 340–354° for 80 days the alloy consists predominately of MgZn, as shown by crystallographic examination. Thermal data afford additional evidence for the formation of MgZn.

R. T.

**System iron-antimony.** P. FOURNIER (Rev. Chim. ind., 1935, 44, 195–198; Chem. Zentr., 1936, i, 422).—The system has been studied from 0.5–70% of Sb. With 60% of Sb, the position of the magnetic transformation is unaltered; the alloy with 70% of Sb is non-magnetic. The solubility of Sb in  $\alpha$ -Fe increases with rise of temp. up to 35% at the eutectic temp., 1060°. FeSb undergoes a transition at 620°. The addition of Sb to steels produces brittleness.

J. S. A.

**Magnetic stability of ferromagnetic iron alloys.** I. V. S. MESSKIN and J. M. MARGOLIN (Z. Physik, 1936, 101, 456–477).—The magnetic stability of Fe alloys increases with increasing concn. of the solid solution and homogenisation of the structure. High-resistance alloys of technical interest are described.

A. B. D. C.

**Phase transformations in the solid state in iron-chromium alloys.** N. N. KURNAKOV and N. I. KORENOV (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 85–98).—Thermal, conductivity, and hardness data confirm the formation of the compound FeCr in Fe-Cr alloys subjected to prolonged heating at 950°. The solid solutions formed by FeCr with Fe have a lower conducting power than those formed by FeCr in Cr.

R. T.

**Formation of liquid eutectic alloys.** N. V. GEVELING (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 63–83).—When molten Cd and Bi or Sn are mixed a fall in temp. results, which is at a max. when the components are present in the same proportions as in the eutectic alloy. No temp. effect is obtained by adding one of the components to a mixture containing the same component in excess of that present in the eutectic alloy. Liquid eutectic alloys are regarded as solutions of one or the other component in the pure eutectic. A sharp break occurs in the  $d$ - and  $\pi$ -concn. curves of the system H<sub>2</sub>O-NaCl at the eutectic composition (23.5% NaCl), suggesting that the mixtures are solutions of H<sub>2</sub>O or NaCl in the eutectic.

R. T.

**Hall effect in antimony-tellurium and antimony-silver alloys.** E. VAN AUBEL (Compt. rend., 1936, 203, 614–615).—The Hall effect and the thermoelectric power of Sb are reduced to 64% and 70% of their respective normal vals. by 4.26% of Te. Formation of the compound Ag<sub>3</sub>Sb is indicated by the variation of Hall effect for a series of Sb-Ag alloys.

H. J. E.

**Electrical conductivity and diagram of state for binary alloys.** XXI. System palladium-chromium. G. GRUBE and R. KNABE. XXII. System palladium-manganese. G. GRUBE, K. BAYER, and H. BUMM (Z. Elektrochem., 1936, 42, 793–804, 805–815).—XXI. Evidence has been obtained for the existence of Pd<sub>2</sub>Cr<sub>3</sub>, which forms solid solutions with Pd, but not with Cr. Cr<sub>2</sub>O<sub>3</sub> dissolves in molten Cr.

XXII. The equilibrium diagram has been deter-

mined by thermal, electrical conductivity, microscopical, and X-ray methods. The compounds Pd<sub>3</sub>Mn, and PdMn are formed.

E. S. H.

**Magnetic susceptibility and diagram of state for binary alloys.** II. System palladium-manganese. G. GRUBE and O. WINKLER (Z. Elektrochem., 1936, 42, 815–830; cf. A., 1935, 291).—The results support those obtained by thermal and other methods (cf. preceding abstract).

E. S. H.

**Magnetic susceptibility of binary alloys of thallium.** (Miss) A. W. DAVID and J. F. SPENCER (Trans. Faraday Soc., 1936, 32, 1512–1516).—Magnetic susceptibilities ( $\chi$ ) of complete series of Tl-Bi and Tl-Cd alloys have been measured. The existence of compounds Bi<sub>5</sub>Tl<sub>3</sub> and Bi<sub>2</sub>Tl<sub>3</sub> is indicated.  $\chi$  for Tl-Cd alloys conforms to the simple mixture rule.

A. J. E. W.

**Theory of equilibrium in alloys.** I. W. HUME-ROTHERY (Phil. Mag., 1936, [vii], 22, 1013–1047).—The effect of lattice distortion on the  $\alpha$ -solid solubilities of certain *B* sub-group metals in Cu and Ag has been investigated, and is discussed in relation to the electron concn. existing in the alloys at the solubility limits, and to the causes of lattice distortion. Possible types of ternary solid solubility isothermals, and the systems in which they occur, are reviewed. One of these types is characteristic of systems containing two components which unite to form a compound; a theoretical treatment of such ternary systems is given.

A. J. E. W.

**Structural change and distortion of the ordered distribution of atoms in metallic mixed phases by plastic deformation.** H. J. SEEMANN (Naturwiss., 1936, 24, 618–619).—The disordering effect of plastic deformation on metallic mixed phases observed with Cu<sub>3</sub>Au and Ni<sub>3</sub>Mn has also been found to occur with a Cu-Pd alloy (47 at.-% Pd). The sp. resistance increases steadily as the arrangement of atoms becomes more disordered, the val. for the completely disordered state being unaffected by cold-working. This example is noteworthy since in addition to a change in the ordered distribution of atoms there is also a lattice change.

A. J. M.

**Velocity of dissolution of gold, silver, and copper alloys in aqueous cyanides in connexion with the phase diagrams of the systems: gold-copper, silver-copper, and gold-silver.** I. N. PLAKSIN and S. V. SCHIBAIEV (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 159–182).—The velocity of dissolution ( $V$ )-composition diagrams for Au-Cu alloys in 0.15–0.6% KCN at 19° have two max., corresponding with the compounds AuCu and AuCu<sub>2</sub>. The  $V$  of Cu from Ag-Cu alloys is least, and that of Ag greatest, at the eutectic point; no Ag is dissolved from alloys containing <37 at.-% Ag. The  $V$  of Au from Au-Ag alloys falls with increasing [Au] to a min. at 40 at.-%, and then rises to a max. at 60 at.-%. The [KCN] giving max.  $V$  of Au from Au, Au-Ag and Au-Cu are, respectively, 0.25, 0.30, and 0.35%. R. T.

**System iron-cobalt-copper.** W. JELLINGHAUS (Arch. Eisenhüttenw., 1936–1937, 10, 115–118).—Cu, Co, and Fe are completely miscible in the liquid state, but separation into two solid phases occurs in

all alloys with 8–96% Cu on solidification. Alloys within a small range in the Fe corner of the ternary diagram solidify as  $\delta$  Fe solid solution and all other alloys with  $\geq 8\%$  Cu as  $\gamma$  Fe-Co solid solution. The  $\gamma$ - $\alpha$  transformation occurs in all alloys on the Fe side of a straight line joining the Cu corner with the 21% Fe point on the Fe-Co side. Addition of Co to Fe-Cu alloys raises the  $\gamma \rightleftharpoons \alpha + \text{Cu}$  eutectoid point to a max. on the line joining the Cu corner with the 50:50 Fe-Co point and then rapidly decreases it to room temp. The existence of FeCo has been confirmed by X-ray analysis and  $d$  measurements.

A. R. P.

**Solubility of methyl chloride and ethyl chloride in certain solvents at  $-10^\circ$  to  $20^\circ$ , at pressures less than atmospheric.** S. I. KAPLAN and M. A. ROMANTSCHUK (J. Gen. Chem. Russ., 1936, 6, 950–954).—Data are recorded for  $(\text{CH}_2\text{Cl})_2$  and  $\text{CCl}_4$  at 100–760 mm.; the former is always the better solvent.

J. J. B.

**Mutual solubilities of hydrocarbons. I. F-p. curves of dotriacontane (dicetyl) in propane and butane.** W. F. SEYER and R. FORDYCE (J. Amer. Chem. Soc., 1936, 58, 2029–2031).—The data indicate the occurrence of two forms of dotriacontane. The variation of  $n$  with temp. shows a transition point at  $55^\circ$ .

E. S. H.

**Thermal variation of electrical birefringence of a liquid mixture presenting a critical point of miscibility.** A. GOLDET (Compt. rend., 1936, 203, 716–718).—Variation of the Kerr effect with temp. for a mixture of  $\text{PhNO}_2$  and  $\text{C}_7\text{H}_{16}$  has been investigated in the neighbourhood of the crit. solution temp.  $T_c$ . The effect increases sharply as  $T_c$  is approached from higher temp., probably owing to changes in the electric field in the liquid.

A. J. E. W.

**Influence of addition of salts on the water-phenol system.** A. BANCHETTI (Atti Soc. Toscana Sci. Nat., 1935, 44, No. 3, 5 pp.; Chem. Zentr., 1936, i, 314).—Addition of  $c$  g.-mols. of KCl per 1000 g. to a mixture of 34.8% of PhOH and 65.2% of  $\text{H}_2\text{O}$  raises the crit. solution temp. by  $t^\circ = 64.87c^{0.87}$ .

H. N. R.

**System nitrobenzene-sulphuric acid-water.** K. C. BAILEY and J. HILTON (J.C.S., 1936, 1571).— $\text{PhNO}_2$  and  $\text{H}_2\text{SO}_4$  are miscible in all proportions at  $17^\circ$ . Miscibility data are given for mixtures of  $\text{PhNO}_2$ ,  $\text{H}_2\text{O}$ , and  $\text{H}_2\text{SO}_4$  at  $17^\circ$ .

R. S.

**Solubility of nitrogen in water at pressures up to 4500 kg. per sq. cm.** J. BASSET and M. DODÉ (Compt. rend., 1936, 203, 775–777).—Measurements at  $18^\circ$  are recorded. The solubility increases with the pressure up to approx. 3000 kg. per sq. cm. and then decreases up to 4500 kg. per sq. cm. Several days are needed for saturation at the higher pressures.

H. J. E.

**Partial vapour pressures of methylamine solutions.** W. A. FELSING and B. A. PHILLIPS (J. Amer. Chem. Soc., 1936, 58, 1973–1975).—Partial v.p. of aq.  $\text{NH}_2\text{Me}$ ,  $\text{NHMe}_2$ , and  $\text{NMe}_3$ , respectively, have been determined over the concn. range 0.2–2.5M. The v.p. of liquid  $\text{NMe}_3$  ( $-20^\circ$  to  $45^\circ$ ) is given by  $\log_{10} p(\text{mm.}) = -1410.5/T + 8.574 - 0.0021158T$ ;  $d$ ,

determined over the same temp. range, is given by  $0.87406 - 4.433 \times 10^{-4}T - 1.29236 \times 10^{-4}T^2$ . The calc. b.p. is  $2.90^\circ$ , and calc. heat of vaporisation 5706 g.-cal. per mol. The calc. free energy of solution (in g.-cal. per mol.) is 3474 for  $\text{NHMe}_2$ , 2991 for  $\text{NH}_2\text{Me}$ , and 2090 for  $\text{NMe}_3$ .

E. S. H.

**Solubility and activity of the halogenates of some bivalent metals. III. Solubility and activity of radium iodate in water and in solutions of electrolytes.** A. POLESICKI and P. TOLMATSCHEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 319–320).—The solubility has been determined in  $\text{H}_2\text{O}$  at  $0$ – $100^\circ$ , and in solutions of  $\text{KNO}_3$ ,  $\text{Ca}(\text{NO}_3)_2$ , and  $\text{KIO}_3$  at  $25^\circ$ . The activity coeffs. at different ionic strengths have been calc.

D. C. J.

**Solubility of solids in liquefied gases. Solubility of  $\text{KNO}_3$  and  $\text{NaCl}$  in liquid ammonia.** A. I. SCHATTENSTEIN and M. M. VIKTOROV (Acta Physicochim. U.R.S.S., 1936, 5, 45–62; cf. A., 1934, 1304).—A method for the accurate measurement of solubilities of solids in liquefied gases is described. Sources of error are discussed and published data critically examined.

F. L. U.

**Effect of one salt on the solubility of another. VII. Solubilities of cobaltammines in aqueous sodium, potassium, and barium thiocyanates.** J. R. PARTINGTON and H. J. STONEHILL (Phil. Mag., 1936, [vii], 22, 857–882).—Data for  $[\text{Co}(\text{NH}_3)_5\text{NCS}](\text{NO}_3)_2$  and  $[\text{Co}(\text{NH}_3)_5\text{NCS}]_2$  are recorded. The results are not in accord with the Debye-Hückel theory, assuming either point ions or finite ionic diameters. The La Mer equation applies when the ionic strength is  $\geq 0.52$ , provided that a val. for the mean ionic radius characteristic of each solution is assumed; this val. is not simply related to the crystallographic ionic diameters for the ions present.

A. J. E. W.

**Solubility of cobaltous iodate in presence of sodium chloride, sodium iodate, and cobaltous sulphate.** H. M. TRIMBLE (J. Amer. Chem. Soc., 1936, 58, 1868–1869).—Data at  $30^\circ$  are recorded.

E. S. H.

**Solubility of cupric oxide in alkali and the second dissociation constant of cupric acid. Analysis of very small amounts of copper.** L. A. McDOWELL and H. L. JOHNSTON (J. Amer. Chem. Soc., 1936, 58, 2009–2014).—The solubility of  $\text{CuO}$  in  $0.04$ – $8.4N$ -KOH and in  $2.2$ – $4.2N$ -NaOH at  $25^\circ$  has been determined. The calc. dissociation const. for  $\text{HCuO}_2' = \text{H}^+ + \text{CuO}_2''$  is  $7.9 \times 10^{-14}$ . The relative proportions of  $\text{HCuO}_2'$  and  $\text{CuO}_2''$  in the solutions have been evaluated. The solubility of  $\text{CuO}$  in  $\text{H}_2\text{O}$  is  $3 \times 10^{-5}$  g.-mol. per litre. A potentiometric method for the determination of Cu in low concns. is described.

E. S. H.

**Derivation of a general expression for the velocity of dissolution of a solid body.** R. L. MÜLLER (Acta Physicochim. U.R.S.S., 1936, 4, 481–493).—The dissolution of a solid over which a liquid is flowing is considered mathematically.

C. R. H.

**Coefficient of fractionation of radium and its isotopes in the crystallisation of barium chlorate.** B. GOLDSCHMIDT (Compt. rend., 1936, 203, 617–

618).—Data are recorded for the ratio of the concns. of Ra, Ac-X, and Th-X in crystals and mother-liquor, on slowly crystallising aq.  $\text{Ba}(\text{ClO}_3)_2$  solutions at 30°. The distribution coeff. is the same for the three isotopes.

H. J. E.

**Theory of adsorption of radioactive elements on polar crystals.** A. P. RATNER (*Acta Physicochim. U.R.S.S.*, 1936, 4, 889—898).—Equations are deduced for the exchange adsorption of ions which do not give solid solutions with the adsorbing crystal and also for the influence of foreign ions.

H. J. E.

**Inner adsorption in salt crystals. IV.** D. BALAREV (*Z. anal. Chem.*, 1936, 106, 349—353).—Polemical, in reply to Kolthoff (this vol., 677).

J. S. A.

**Mechanism of the phenomenon of base exchange.** M. G. AUSTERWEIL (*Bull. Soc. chim.*, 1936, [v], 3, 1782—1790; cf. A., 1932, 1007).—It is confirmed that base exchange is governed by the laws of distribution, the solid base exchanger playing the role of a solvent non-miscible with the solution containing the cations. The extraction formula is related to the empirical adsorption formula by which the phenomenon has been previously represented.

J. W. S.

**Adsorption of radium ions on glass, and Guy's theory.** V. VDOVENKO and A. SAMOILOVICH (*Acta Physicochim. U.R.S.S.*, 1936, 4, 613—616).—Theoretical. The adsorption isotherms for Ra ions at concns. from  $10^{-7}$  to  $10^{-11}$  mol. per litre and  $p_H$  2—7 can be explained in terms of Guy's theory.

O. D. S.

**Polymolecular adsorbed films. I. Adsorption of argon on salt crystals at low temperatures, and the determination of surface fields.** R. S. BRADLEY (*J.C.S.*, 1936, 1467—1474; cf. A., 1931, 421).—The equation  $T \log_{10} (p_0/p_a) = K_1 K_2^a$ , where  $p_0$  and  $p_a$  are the saturation pressures of the bulk liquid and the adsorbed film, respectively, has been deduced for the formation of thick films by polarisation. Data relative to the adsorption of A on powdered  $\text{CuSO}_4$ ,  $\text{Al}_2(\text{SO}_4)_3$ , and KCl at 84.5—88° abs. are in good agreement with the equation. Thick films are formed on the two former, but not on KCl, polarisation being small in this case due to anion and cation having approx. the same size. The induced dipole moments and the surface fields are calc.

R. S.

**Adsorption of vapours on glass spheres. I. Adsorption of nitrogen.** J. L. SHERESHEFSKY and C. E. WEIR (*J. Amer. Chem. Soc.*, 1936, 58, 2022—2029).—Adsorption data for liquid-air temp. are recorded and discussed in relation to adsorption theories. At low pressures the adsorption isotherm shows recession of the equilibrium pressure. Measurements of the thermal flow effects of  $\text{H}_2$  and He show agreement at pressures corresponding with equal mean free paths.

E. S. H.

**Adsorption of hydrogen and nitrogen on iron-molybdenum ammonia catalysts.** V. ROITER, S. GAUCHMANN, and M. LEPERSON (*Acta Physicochim. U.R.S.S.*, 1936, 4, 145—158).—The adsorption of  $\text{H}_2$  on Fe-Mo (I) and Fe-Mo- $\text{Al}_3$  (II) catalysts is rapid and reversible at low temp., but slow and irreversible

between 0° and 450°. Adsorption is slowest with old (I) and fastest with (II). The presence of  $\text{Al}_2\text{O}_3$  increases the no. of active centres and prevents the reduction of catalyst surface by recrystallisation, but has little effect on the adsorptive capacity. In the case of  $\text{N}_2$ , the rapid, reversible adsorption could alone be observed up to 450°, and the heats of adsorption for (I) and (II) are 5500 and 12,000 g.-cal., respectively.

R. S.

**Adsorption properties of promoted iron oxide in relation to the distribution of the promotor in the oxide form of the ammonia catalyst.** A. DUBROVSKAJA and N. I. KOBOSOV (*Acta Physicochim. U.R.S.S.*, 1936, 4, 841—858).—Adsorption isotherms of  $\text{O}_2$  on  $\text{Fe}_2\text{O}_3$  and on  $\text{Fe}_2\text{O}_3$  promoted with 10% of  $\text{Al}_2\text{O}_3$  have been measured at —190° and 400°. When heated in vac. at 600°,  $\text{Fe}_2\text{O}_3$  crystallises completely. The adsorption decreases with the degree of crystallisation, as determined by X-rays. The rate of desorption at 150—400° has been measured. The activation energy for desorption is the same in the promoted and unpromoted oxide. 10% of  $\text{Al}_2\text{O}_3$  reduces the sp. adsorption of  $\text{Fe}_2\text{O}_3$  by 4—5 times. In  $\text{Fe}_2\text{O}_3$  with relatively large crystals, 1% of  $\text{Al}_2\text{O}_3$  suffices to cover approx. 50% of the crystal surface.

H. J. E.

**Recombination of atomic hydrogen in adsorbed layers.** O. I. LEPUNSKI (*Acta Physicochim. U.R.S.S.*, 1936, 5, 271—298).—The adsorption and recombination of H atoms on Ni, Fe, Cu, and Al between —180° and 0° has been studied. An equation for the recombination velocity has been deduced assuming an activated surface diffusion of H, which is in good agreement with the results. Deviations are attributed to inhomogeneity of the surface. Metals which are most efficient as hydrogenation catalysts give the greatest recombination velocities. The energy of activation of the surface diffusion calc. from the temp. coeff. is < that calc. from the abs. velocity of recombination owing to the operation of a steric factor, the nature of which is discussed.

R. S.

**Influence of  $p_H$  on adsorption from solutions.** N. A. YAJNIK, D. N. GOYLE, I. DAS, and J. R. JAIN (*Kolloid-Z.*, 1936, 77, 99—103).—Measurements of the adsorption of different dyes by  $\text{SiO}_2$  gel,  $\text{Al}(\text{OH})_3$ , and animal charcoal show that the acid dyes are adsorbed most strongly by the acid adsorbents and the basic dyes by  $\text{Al}(\text{OH})_3$ . Addition of acid reduces the adsorption of methylene-blue and Bismarck-brown, but increases the adsorption of water-blue and picric acid. The role of  $p_H$  is discussed.

E. S. H.

**Adsorption of bromine ions by argillaceous sludges.** V. I. NIKOLAEV, A. M. SOLOVOV, and M. A. FRISCHMUT (*Ann. Sect. d'Anal. Physico-Chim.*, 1936, 9, 317—326).—Adsorption of  $\text{Br}^-$  by clay or argillaceous sludge from salt lake  $\text{H}_2\text{O}$  is at a max. when the latter has  $d$  1.32. Adsorption of KBr or NaBr does not take place in absence of chlorides.

R. T.

**Action of potassium on the mechanism of activation of charcoal.** B. BRUNS and E. ZOLOTAREVSKAJA (*Acta Physicochim. U.R.S.S.*, 1936, 5, 63—78; cf. A., 1933, 1112).—The adsorptive capacity for  $\text{C}_5\text{H}_{12}$  of activated sugar C decreases linearly with

increasing K content between 0.02 and 7.8%. It is immaterial whether  $K_2CO_3$  is added initially to the sugar, or the C is heated in K vapour before activation. The effect is due to the greater rapidity with which the surface layer burns in the presence of K.

F. L. U.

**Discontinuities in the sorption process.** A. G. FOSTER (Trans. Faraday Soc., 1936, 32, 1559—1569).—Using a static vac. method, no well-defined discontinuities are observed in the adsorption isotherms of  $CCl_4$  on  $SiO_2$  gel at 25°. After prolonged heating at 120° with  $CCl_4$ , residual  $H_2O$  is removed from the gel and the shape of the isotherm alters, resulting in greatly increased adsorption at low pressures. Adsorption measurements of  $H_2O$ ,  $EtOH$ , and  $CCl_4$  on  $SiO_2$  gel by the dynamic retentivity method show, when compared with results of the static technique, that the retentivity method is untrustworthy when applied to isotherms of abnormal type. E. S. H.

**Range of action of surface forces.** J. M. MACAULAY (Nature, 1936, 138, 587).—Observations on the creeping of  $H_2O$  between glass plates are described. L. S. T.

**Unimolecular adsorption layers and surface films.** I. Measurement of surface pressure of adsorption layers. A. S. ACHMATOV (Kolloid-Z., 1936, 77, 20—26).—Apparatus is described. E. S. H.

**Surface properties of non-aqueous solutions.** R. ASCHAFFENBURG (Nature, 1936, 138, 644—645).—For solutions of *n*-alcohols in  $NH_3Ph$  the lowering ( $\Delta\gamma$ ) of the surface tension is < for aq. solutions. For equimol. solutions,  $\Delta\gamma$  is the greater the higher is the mol. wt. The  $\gamma$ -concn. curves are of the same type as those for aq. solutions, and for dil. solutions ( $c < 0.1$  g.-mol. per litre)  $\Delta\gamma/c$  is const. In homologous series the influence of an additional  $CH_2$  on the surface energy becomes less as the C chain becomes longer. L. S. T.

**Discussion on surface phenomena. Films.** (Proc. Roy. Soc., 1936, A, 155, 684—711).—E. K. RIDEAL discussed the evidence on which the concept of the oriented mono-layer is based. Two experimental methods, an optical and an electrical, are available for the determination of film uniformity. Other properties of surface films were reviewed.

N. K. ADAM discussed the principal forces stabilising unimol. surface films at an air- $H_2O$  surface: (a) the perpendicular attraction of the  $H_2O$ -sol. groups at or near the end of the mol., and (b) the lateral adhesion between the mols.

G. GEE described the results of an investigation of the autoxidation and polymerisation of unsaturated glycerides (drying oils) spread as mono-layers on the surface of 0.01*N*- $H_2SO_4$  or -HCl.

F. A. ASKEW described a method for the study of unimol. films at liquid-liquid interfaces.

J. S. MITCHELL discussed the photochemical properties of certain complex org. compounds spread in mono-layers at the surface of aq. substrates.

J. H. SCHULMAN. The methods of measuring phase boundary potentials and surface pressures at air-liquid phase boundaries may be used to examine the

interaction between large mols. A new phenomenon is described which consists in the penetration of a film of oriented mols., each possessing a large hydrophobic portion and a dipole situated near the end of the mol., by similar mols. which possess different dipoles and are readily sol.

O. GATTY. Differences in potential between the inside and outside of the isolated skins of the common frog have been measured, and time-potential curves obtained as functions of the composition of the solutions in contact with the skin.

K. GORTER described certain results of work on the spreading of complex proteins.

J. F. DANIELLI discussed the tension at the surface of living cells.

A. HUGHES described experiments on unimol. films of chlorophyll, hæmin, and certain recently isolated metallic phthalocyanine derivatives. L. L. B.

**Alteration of the free surface energy of solids.** I. Vertical-rod method for the measurement of contact angles and effect of heat-treatment on magnitude of contact angles. F. E. BARTELL, J. L. CULBERTSON, and M. A. MILLER. II. Effect of heat-treatment of metals in air. III. Effect of heat-treatment of metals in a vacuum and in several gases. F. E. BARTELL and M. A. MILLER (J. Physical Chem., 1936, 40, 881—888, 889—894, 895—904).—I. A method has been developed for measuring contact and interfacial contact angles against either transparent or opaque solids which can be formed into rods, and has been applied to changes in the adhesion tension of  $H_2O$  on Pyrex glass,  $SiO_2$ , Au, and Pt. The method of cleaning and previous heat-treatment of solids changes the magnitude of the contact angle. Careful annealing of glass decreases the  $H_2O$ -air contact angle on its surface to zero. Ageing of glass and metal surfaces increases the contact angle on them.

II. A method of pretreatment of Au and Pt rods to furnish standard reference surfaces has been developed. Similar standard surfaces could not be obtained on steel treated in air. Treatment of standard Au and Pt surfaces at 100—600° in air for 1 hr. decreases the  $H_2O$ -air contact angle, this decrease being the greater the higher is the temp. of the treatment, but on keeping in air the contact angle gradually increases again. Measurements of the contact angles at  $H_2O$ - $C_6H_6$ ,  $H_2O$ -1- $C_{10}H_7Br$ , and  $H_2O$ - $C_2H_5Br_4$  interfaces indicate that the metals treated at low temp. were fairly strongly organophilic, but at higher temp. became less strongly so or even hydrophilic. The changes are attributed to oxidation and recrystallisation.

III. Standard reference surfaces were prepared on rods of Au, Pt, Cu, 18 : 8 stainless steel, Ag, Al, W, and brass by polishing in  $N_2$  and heating in a vac. at 100°. Heat-treatment in a vac. rendered the surfaces more hydrophilic with rise of temp. of treatment. Heating in gases made them less hydrophilic than when heated in a vac. in the order  $vac. > H_2 > air > N_2$ . All the metals except Pt and W react readily with  $C_2H_5Br_4$  after heating in  $N_2$ , whilst Au, Cu, and brass similarly treated react with 1- $C_{10}H_7Br$ . Al and W react with  $C_2H_5Br_4$  after heating in  $H_2$ .

The contact angles at liquid-air interfaces vary considerably with the metal and its pretreatment.

J. W. S.

**Properties of metallic solutions. III. Surface tension of amalgams.** V. K. SEMENT-SCHENKO, B. P. BERING, and N. L. POKROVSKI [with E. E. SHVAREVA] (*Acta Physicochim. U.R.S.S.*, 1936, 5, 181—192).—The surface tensions of Hg amalgams of Cs, Rb, K, Na, Li, Ba, Sr, Pb, Sn, Ag, Cu, Zn, Bi, Co, Mg, and Cd have been determined at 18–20°. The data are in agreement with Sziszkovski's equation up to a crit. concn.  $c_k$  of active metal,  $c_k$  being a linear function of the ultimate activity. K, Rb, and Cs form surface layers of 3.76, 5.8, and 7.8 mols. thick, respectively, whilst Ba, Li, Na, etc. form unimol. layers. The application of the Gibbs equation to amalgams is discussed.

R. S.

**Properties of metallic solutions. II. Surface tension of amalgams.** B. P. BERING and N. L. POKROVSKI (*Acta Physicochim. U.R.S.S.*, 1936, 4, 861—872; cf. this vol., 1192, 1331).—The surface tension of amalgams of Hg with 0–0.2 at-% of Cs, Rb, K, Na, Li, Ba, Sr, Mg, Pb, Sn, Cu, Ag, Cd, Bi, Co, and Zn has been measured at 20° by the method of max. bubble pressure in an atm. of  $H_2$ . H. J. E.

**Electrocapillarity curve of gallium. II.** A. MURTAZAJEV and A. GORODETZKAJA (*Acta Physicochim. U.R.S.S.*, 1936, 4, 75—84; cf. A., 1928, 1193).—More exact results have been obtained. PhOH,  $iso-C_6H_{11}OH$ , pyrogallol,  $CS(NH_2)_2$ , and KI displace the max. of the electrocapillarity curve of Ga in the same direction as in the case of Hg, but the degree of adsorption is different.

R. S.

**Mechanical properties of foams. I.** A. SIEHR (*Kolloid-Z.*, 1936, 77, 27—32).—In a column of foam (up to 50 cm.) the sideways pressure exerted on the tube walls increases linearly with the height of the foam. Foam pressure and wetness (c.c. of liquid/c.c. of foam) decrease with time, although not proportionally. Dil. saponin solutions give drier and lighter foams than conc. saponin solutions.

E. S. H.

**Wetting power of powders of different degrees of dispersion.** Z. V. VOLKOVA (*Acta Physicochim. U.R.S.S.*, 1936, 4, 635—644; cf. A., 1935, 1071).—The velocity of wetting by  $H_2O$  and PhMe of powdered quartz (I), calcite (II), fluorite (III), and corundum (IV) of different degrees of dispersion has been measured. The ratio  $r/r_0$  of the penetration radii for  $H_2O$  and PhMe, respectively, remains const. for (I) and (II) at medium dispersion, but falls at high dispersions. This decrease is ascribed to the formation of  $H_2O$  layers between the particles.  $r/r_0$  for (III) and (IV) decreases with decrease in particle size. For particles covered with an adsorbed layer of oleic acid  $r/r_0$  decreases to 0 when the surface is only partly covered with acid.

O. D. S.

**Anomalies of thin liquid layers. III. Ultramicroscopic study of solvent envelopes and of the fundamental swelling process.** B. DERJAGUIN [with E. OBUCHOV] (*Acta Physicochim. U.R.S.S.*, 1936, 5, 1—22; cf. A., 1934, 1068).—A method is described for determining, by means of an optical lever, the pressure exerted by a thin film of liquid in

contact with lyophilic surfaces. When  $H_2O$  penetrates between plane parallel plates of mica, the resulting linear separation of the plates varies inversely with the pressure opposing separation, e.g., 21  $\mu$  at 4.4, and 0.55  $\mu$  at 14.0 g. per sq. cm.  $CCl_4$  produces no effect with mica, but when saturated with  $H_2O$  gives the same val. as does pure  $H_2O$ . At a steel surface  $H_2O$  is inactive, whilst paraffin oil gives an effect which is increased by addition of oleic acid. The observed effect is invoked to explain the swelling of ppts. and colloids. The subject is discussed theoretically.

F. L. U.

**Film formation from emulsions.** H. WAGNER and G. FISCHER (*Kolloid-Z.*, 1936, 77, 12—20).—Films formed by the drying of emulsions of the  $H_2O$ -in-oil and oil-in- $H_2O$  types are classified in a scheme in which the extreme members are (a) reversible, hydrophilic, and porous (e.g., glue), and (b), irreversible, hydrophobic, and non-porous (e.g., lacquer), respectively. The structure of dried films from several emulsions has been examined microscopically and is discussed in relation to the system of classification.

E. S. H.

**Formation of phosphatide films on cholesterol.** H. G. B. DE JONG and N. I. JOUKOVSKY (*Compt. rend. Soc. Biol.*, 1936, 123, 299—302).—The film consists of mols. of both phosphatide (I) and cholesterol, the latter acting as an activator for (I), contrary to the effect of  $TiO_2$ .

H. G. R.

**Osmotic pressure and viscosity of polystyrenes.** (MME.) A. DOBRY and (MME.) A. SCHWOB (*Bull. Soc. chim.*, 1936, [v], 3, 1790—1794).—In sufficiently dil. solution the mol. wt. of polystyrenes calc. from the osmotic pressure is independent of the solvent, but decreases rapidly with increasing concn. and for 0.5% solutions is half the true mol. wt. This change is attributed to colloidal effects. Fractional pptn. of a polystyrene yields fractions with the same mol. wt., but differing viscosities.

J. W. S.

**Complex formation involving weak acids. XV. Optical rotation of *l*-malic and *l*-lactic acids during neutralisation with sodium hydroxide.** H. T. S. BRITTON and A. A. MOSS (*J.C.S.*, 1936, 1487—1489).—The rotations of undissociated malic (I) and lactic (II) acids and the malate, hydro-malate, and lactate ions have been determined. The variation of rotation during titration of (I) and (II) with NaOH is given by the sum of the mol. and ionic rotations.

R. S.

**Raman effect in non-aqueous electrolytic solutions. II. Solutions of antimony trichloride.** M. ASCHKINASI, P. KURNOSOVA, and V. FINKELSTEIN (*Acta Physicochim. U.R.S.S.*, 1936, 4, 317—324; cf. this vol., 1203).—The Raman spectra of 5.8—25% solutions of  $SbCl_3$  in  $Et_2O$  have been determined. Undissociated mols. exist in solution and there is no evidence of compound formation, since no new lines appear. The Raman spectra of 15—22% solutions of  $SbCl_3$  in  $C_6H_6$  show two new lines, of frequencies 477 and 1236  $cm^{-1}$ , corresponding with the compound  $2SbCl_3 \cdot C_6H_6$ .

R. S. B.

**High-frequency measurement of the dielectric constant of dilute solutions of salts in different solvents.** M. BEAUVILAIN (Ann. Physique, 1936, [xi], 6, 502—560).—The dielectric const. of 45 salts in  $H_2O$  and of KCl in glycerol and  $H_2O$ -glycerol mixtures decreases linearly as the salt concn. increases. In general, the decrease is the more marked the higher is the valency of the ions and the greater the proportion of  $H_2O$  in the mixtures. The dielectric const. of solutions of KCl in EtOH, MeOH, BuOH,  $COMe_2$ , glycol, and glycerol, and in mixtures of these with  $H_2O$ , decreases at a certain concn. of solute, which depends on the  $H_2O$  content of the mixtures. The lowering depends on the non-aq. constituent of the solvent. N. M. B.

**Magnetic study of colour changes in cobalt chloride.** II. S. S. BHATNAGAR, A. N. KAPUR, and P. L. KAPUR (J. Indian Chem. Soc., 1936, 13, 489—493).—The mol. magneto-optic rotation of  $CoCl_2 \cdot 6H_2O$  in  $H_2O$ ,  $C_6H_{11}OH$ , and HCl varies with concn., although the effect is only just detectable in  $H_2O$ . This disagrees with the theory that colour change is due to formation of anhyd.  $CoCl_2$ , but supports the theory that complexes of the type  $CoCl_3'$  and  $CoCl_3''$  are present (cf. A., 1932, 1083). C. R. H.

**Analysis of magnetogalvanic effect.** V. SHVONEN and P. VEIJOLA (Z. Elektrochem., 1936, 42, 833—837).—Changes in the effect with time for Cu in aq.  $Cu(NH_3)_4Cl_2$  and Fe in aq.  $FeCl_3$  are traced to the reactions  $Cu^{++} + Cu = 2Cu^+$  and  $2Fe^{+++} + Fe \rightleftharpoons 3Fe^{++}$ . E. S. H.

**Colloid synthesis by means of gaseous explosions and colloidchemical investigations on disperse systems so prepared.** N. SATA (Bull. Chem. Soc. Japan, 1936, 11, 598—627).—By the method previously described (cf. this vol., 1198, 1337), sols of Hg, Se, and S have been prepared and examined. It was necessary to use  $Na_2S$  or NaI as a stabiliser for the Hg sols. The vals. of  $\eta$  for the sols are almost the same as for  $H_2O$  and the vals. of  $\gamma$  only slightly  $>$  for  $H_2O$ . Electrophoretic properties and coagulation by means of halides have also been studied. C. R. H.

**Mechanism of the formation of fogs by ultrasonic waves.** K. SOLLNER (Trans. Faraday Soc., 1936, 32, 1532—1536).—The production of the fogs is traced to the collapse of cavities which is brought about by external gas pressure or by the v.p. of the irradiated liquid. E. S. H.

**Action of ultrasonic waves on suspensions.** F. J. BURGER and K. SOLLNER (Trans. Faraday Soc., 1936, 32, 1598—1603).—In suspensions of particles of microscopic dimensions and in colloidal solutions containing rod- or plate-like particles orientation is produced under the influence of ultrasonic waves. Conc. rheopectic suspensions of gypsum, kaolin, etc. are solidified by ultrasonics of low and medium energy; at higher energies the pastes are liquefied as a result of cavitation. Mixtures of sea-sand or quartz powder with  $H_2O$ , which are normally dilatant, lose this property when exposed to ultrasonic waves. E. S. H.

**Behaviour of aerosols in the acoustic field.** III. Theory of acoustic coagulation. O. BRANDT,

H. FREUND, and E. HIEDEMANN (Kolloid-Z., 1936, 77, 103—115; cf. this vol., 794).—Theoretical.

E. S. H.

**Aerogels. I. Structure of metallic oxides.** V. CAGLIOTI and O. D'AGOSTINO (Gazzetta, 1936, 66, 543—548).—The structures of  $Fe_2O_3$  and of  $Al_2O_3$ , prepared as aerogels by oxidising Fe and Al vapours in electric arcs with a strong current of air, have been investigated by X-rays. Both oxides have the  $\gamma$ -phase structure. O. J. W.

**Measurement of light scattered by disperse systems by means of tubular scattering cells.** B. KLAGES and H. KLUMB (Physikal. Z., 1936, 37, 725—726).—Tubular photo-electric cells can be used for the investigation of scattering of light by stationary or moving disperse systems. Aerosols containing 10 mg. per cu.m., and hydrosols containing 1 mg. per litre, could be detected. The apparatus is also useful for the detection of light scattered by biological preps. and for the study of fluorescence. A. J. M.

**Gold colloids in sylvine crystals.** J. C. REPSCHÉ (Acta Physicochim. U.R.S.S., 1936, 5, 173—180).—The absorption curves of colloidal Au in KCl agree closely with Mie's theory, but the particle size bears little relation to the [Au]. R. S.

**Colloid-chemical phenomena in metals. III. Micellar structure of liquid and solid metals and alloys.** J. A. KLJATSCHKÓ (Kolloid-Beih., 1936, 44, 387—426; cf. this vol., 25).—Published evidence is reviewed. E. S. H.

**Colloid-chemical processes at high temperatures. II. Reduction of the disperse phase with hydrogen under pressure.** S. I. DJATSCHKOVSKI (Kolloid-Z., 1936, 77, 74—78; this vol., 287).—At 200° and 200 atm. colloidal  $Fe(OH)_3$  is reduced by  $H_2$  to Fe,  $WO_3$  and  $V_2O_5$  to  $W_3O_8$  and  $V_2O_4$ , respectively.  $Cr(OH)_3$  is not reduced under these conditions. E. S. H.

**Classification of emulsions.** A. RABINERSON and L. KREMNEV (Acta Physicochim. U.R.S.S., 1936, 5, 105—110). F. L. U.

**Appearance of some emulsions.** W. S. URBANSKI (Acta phys. polon., 1934, 3, 39—41; Chem. Zentr., 1936, i, 29).—A reply to Piekara (A., 1934, 1306). Ag emulsions show evidence of an ordered structure. J. S. A.

**Molecular and colloid solubility of acid and salt dyes, especially benzopurpurin. II. Dissolution of acid dyes in sodium hydroxide+neutral salt and in sodium hydroxide+ethyl alcohol.** W. OSTWALD and R. WALTER (Kolloid-Z., 1936, 77, 54—64; cf. this vol., 1338).—Small amounts of neutral salts increase the solubility of benzopurpurin in NaOH, but large amounts cause flocculation. EtOH behaves similarly to neutral salts at low concns., but at higher concns. there is a sp. solubility of the dye in EtOH. The relative roles of chemical reaction, peptisation, and dissolution in these processes are discussed. E. S. H.

**Spontaneous structure formation of ferric hydroxide sols.** G. FUCHS and A. RABINERSON (Acta Physicochim. U.R.S.S., 1936, 4, 441—452).— $Fe^{III}$  salts in the intermicellar liquid of freshly pre-

pared  $\text{Fe}(\text{OH})_3$  sols gradually hydrolyse, hydrolysis terminating after 3–6 days according to whether the colloid content is low or high. The hydrolysis is accompanied by a decrease in  $[\text{Fe}^{+++}]$  followed by desorption and gradual coagulation. Even when hydrolysis has ceased and there is no further decrease in charge, coagulation continues at a velocity depending on the val. of the adjusted  $\zeta$ -potential.

C. R. H.

**Influence of adsorbed cations on structure formation in aluminosilicate suspensions.** A. RABINERSON and V. KNIASEV (*Acta Physicochim. U.R.S.S.*, 1936, 5, 93–104).—Viscosities and times of setting to a thixotropic gel have been determined for 8% suspensions of three varieties of kaolin containing adsorbed  $\text{H}^+$  and  $\text{Na}^+$  in varying proportions. Setting takes place only when the kaolin is partly saturated with  $\text{Na}^+$ . More conc. (10–20%) suspensions can develop structure when fully saturated either with  $\text{H}^+$  or with  $\text{Na}^+$ . The existence of an optimum Na content is explained by the tendency of this ion to cause both increased hydration and peptisation, the first of which promotes whilst the second hinders the formation of structure.

F. L. U.

**Activity of ions in colloidal solutions. I. Suspension effect in the ultrafiltration of positive colloids.** P. VASSILIEV, T. GATOVSKAJA, and A. RABINOVITSCH. **II. Suspension effect in the ultrafiltration and centrifuging of negative colloids.** T. GATOVSKAJA and P. VASSILIEV (*Acta Physicochim. U.R.S.S.*, 1936, 4, 1–36, 37–50).— $\text{Fe}_2\text{O}_3$  sols of different concns. have been subjected to ultrafiltration and the activities of  $\text{Cl}^-$  and  $\text{H}^+$  in the ultrafiltrate and the residue determined potentiometrically. The vals. of  $\alpha_{\text{Cl}^-}$  and  $\alpha_{\text{H}^+}$  in the ultrafiltrate remain approx. const. with increasing sol concn., whilst  $\alpha_{\text{Cl}^-}$  increases and  $\alpha_{\text{H}^+}$  decreases in the direction ultrafiltrate  $\rightarrow$  sol  $\rightarrow$  residue, according to linear functions of the  $\text{Fe}_2\text{O}_3$  concn. The ratio  $\alpha_{\text{Cl}^-} : \alpha_{\text{H}^+}$  is const. on both sides of the ultrafilter in agreement with the Donnan equilibrium condition. A theory based on the Donnan equilibrium is put forward.

**II.  $\text{WO}_3$ ,  $\text{TiO}_2$ , and  $\text{V}_2\text{O}_5$  sols have been investigated.** The  $\alpha_{\text{H}^+}$  in the ultrafiltrate is const. with increasing sol concn., but in the series ultrafiltrate  $\rightarrow$  sol  $\rightarrow$  residue,  $\alpha_{\text{H}^+}$  increases approx. linearly with sol concn. Similar results are obtained when the system is centrifuged.

R. S.

**High-frequency conductivity of colloidal electrolytes. I. Congo-red and Congo-blue sols.** G. SCHMID and A. V. ERKKILÄ (*Z. Elektrochem.*, 1936, 42, 737–741).—The high-frequency conductivity is about 30% > that at low frequencies. The significance of this result in elucidating the electrical structure of colloid micelles is discussed.

E. S. H.

**Physicochemical investigations of photographic emulsions.** C. S. LIALIKOV and V. N. PISKUNOVA (*Acta Physicochim. U.R.S.S.*, 1936, 4, 325–340).—The solubility ( $S$ ) of  $\text{AgBr}$  has been determined at 25–45° in presence of gelatin, 0.00625–1.6M-KBr, 1M- $\text{NH}_3$ , and 0.5M- $\text{KNO}_3$ .  $S$  in  $\text{NH}_3$  decreases on addition of small quantities of  $\text{Br}^-$ , remains const. on further additions, and then in-

creases. The expression  $6.3 \times 10^{-13} [\text{NH}_4\text{OH}]^2 / [\text{Br}^-][\text{Ag}(\text{NH}_3)_2^+]$  remains approx. const. for  $[\text{Br}^-] = 0.00606$ – $0.0995N$ . The val. of  $S$  in  $\text{NH}_3$  in presence of KBr is increased by  $\text{KNO}_3$ , the influence of the  $\text{KNO}_3$  increasing with decreasing  $[\text{KBr}]$ , and the presence of 1% gelatin causes only a slight decrease in  $S$ .

R. S. B.

**Role of dielectric constant, polarisation, and dipole moment in colloid systems. XVII. Swelling and solubility of cellulose derivatives and their relations to dielectric values.** W. L. H. MOLL (*Kolloid-Z.*, 1936, 77, 85–93).—Published data show a relation between the optimum conditions for swelling and the dielectric const., surface tension, and chemical character of the solvent.

E. S. H.

**Electro-kinetic investigation of the organosols of highly polymerised natural substances.** M. TANIGUCHI and I. SAKURADA (*J. Soc. Chem. Ind. Japan*, 1936, 39, 316B).—Cellulose nitrate and acetate are negatively charged in  $\text{COMe}_2$  solution.

A. G.

**Electrolyte coagulation of weakly solvated sols and electrolyte activity. V. Determination of exact coagulation values by turbidity measurements.** H. A. WANNOW (*Kolloid-Z.*, 1936, 77, 46–53; cf. this vol., 1200).—When  $\text{As}_2\text{S}_3$  sols are coagulated by electrolytes, the turbidity decreases and the sedimentation vol. increases with increasing valency of the pptg. ion ( $\text{K}^+$ ,  $\text{Mg}^{++}$ ,  $\text{Al}^{+++}$ ,  $\text{Th}^{++++}$ ). Turbidity measurements are not suitable for the exact determination of coagulation vals.

E. S. H.

**Flocculation of lyophilic colloids by non-electrolytes and salts.** B. JIRGENSONS (*Kolloid-Beih.*, 1936, 44, 285–386).—Published work on the behaviour of sols of ovalbumin, casein and its degradation products, haemoglobin, starch, and lecithin is reviewed and certain regularities are indicated. In flocculation of the pure sols by alcohols and similar non-electrolytes, max. and min. with increasing concn. appear, their positions depending on the dielectric const. of the non-electrolyte and on the  $p_H$  of the solution. With combinations of capillary-active non-electrolytes and salts in low or medium concns. coagulation is more rapid than with non-electrolytes or salts alone, but at higher concns. the non-electrolyte stabilises the sol.

E. S. H.

**Peptisation of colloids by electrolytes. I. Reversion of coagulation with formation of insoluble salts.** P. VASSILIEV and N. DESCHALIT (*Acta Physicochim. U.R.S.S.*, 1936, 4, 51–74).—When  $\text{Fe}(\text{OH})_3$  sol is coagulated by  $\text{Na}_2\text{SO}_4$ ,  $\text{Cl}^-$  is displaced from the surface of the particle to the intermicellar liquid by  $\text{SO}_4^{--}$ . The gel can be peptised by addition of an equiv. amount of  $\text{BaCl}_2$ , with formation of  $\text{BaSO}_4$ , and it has been shown that  $\text{Cl}^-$  is readsorbed during the peptisation. Repeated coagulations and peptisations are possible. Part of the  $\text{BaSO}_4$  is pptd., whilst part remains in the sol, and this has been shown by X-rays to have the ordinary crystal structure. Reversion of  $\text{Al}(\text{OH})_3$  and  $\text{Ti}(\text{OH})_2$  gels is possible, but gels of negative colloids could not be peptised. The formation of  $\text{CaSO}_4$  or  $\text{SrSO}_4$  does not produce reversion, but  $\text{PbCrO}_4$  is efficacious because of its low solubility product.

R. S.

**Elastoidin fibres. I. Imbibition of water.** E. FAURÉ-FREMIET and R. WOELFFLIN. **II. Elastic properties.** E. FAURÉ-FREMIET. **III. Titration curve.** E. FAURÉ-FREMIET and R. WOELFFLIN (J. Chim. phys., 1936, 33, 666—680, 681—694, 695—700).—I. The prep. of elastoidin fibres (I) from the fins of the blue shark is described. The imbibition of  $H_2O$  by dried (I) bears a sigmoid relation to the pressure of the added  $H_2O$  vapour, and the free energy of imbibition falls rapidly as  $H_2O$  is absorbed. In the absence of salts, the imbibition by submerged (I) is const. at  $p_H$  4—11, but rises sharply at  $p_H$  12 and has a sharp max. at  $p_H$  2.4. Neutral salts augment imbibition, the effect corresponding with the Hofmeister series, but inhibit the large absorption at low  $p_H$  vals. The breadth of a fibre in acid increases linearly with imbibition and the length increases linearly to a flat max. equal to the val. at  $p_H$  4—11. The effects of temp. are recorded.

**II.** (I) exist in two interconvertible forms. Modification *A* follows Hooke's law at 7—58°, but has small extensibility. Modification *B*, formed at approx. 62° under zero tension, follows Hooke's law at 63—66° and is highly elastic. Below 62°, *B* undergoes changes, largely permanent, corresponding with the existence of false equilibria.

**III.** (I) absorb acid and alkali strongly at  $p_H$  vals. < 2.5 and > 10, respectively. *A* and *B* at  $p_H$  6.2—7.6 and  $p_H$  5—7, respectively, do not absorb acid or alkali.

J. G. A. G.

**Isoionic point of proteins.** A. PASSINSKI and Z. ZOLOTAREVA (Acta Physicochim. U.R.S.S., 1936, 4, 505—526).—The effect of neutral salts on the iso-electric and isoionic points of ampholytes is discussed theoretically. Measurements of the isoionic points of solutions of gelatin (I) and of ovalbumin (II) in the presence of  $BaCl_2$ ,  $KCl$ , and  $KI$  show that for both proteins  $BaCl_2$  causes a shift of isoionic point towards the acid side, whilst  $KI$  causes a shift to the alkaline side. The isoionic point of (I) is unaltered by  $KCl$ , but that of (II) is shifted to the alkaline side.

O. D. S.

**Solubility and flocculation of proteins and other lyophilic colloids. I.** F. HAUROWITZ and F. MARX (Kolloid-Z., 1936, 77, 65—74).—In the heat-coagulation of ovalbumin and serum solutions there is a small vol. increase, and in blood-pigment solutions a small vol. decrease. The vol. change is about 3—6% of the contraction on adding albumin to  $H_2O$ ; thus, denatured albumin has almost the same degree of hydration as natural albumin. Proteins containing negative exionic groups are pptd. by clupein. Addition of  $NaCl$  inhibits the pptn.; the ppt. has an approx. const. composition. The colloidal structure of proteins and the nature of the solvate sheath are discussed.

E. S. H.

**Adsorption of benzene derivatives by serum colloids and organ pulps.** C. SCAGLIONI (Kolloid-Z., 1936, 77, 78—85).—OH- or  $NH_2$ -derivatives are strongly adsorbed by serum or muscle, but when present together the degree of adsorption is < when present singly. The presence of  $CO_2H$  practically inhibits the adsorption due to OH or  $NH_2$  in the same mol. All the compounds except  $NH_2Ph$  are

more strongly adsorbed by serum and muscle than by liver, spleen, lung, or kidney. The bearing of the observations on metabolism is discussed.

E. S. H.

**Undulating cracks and periodical crystallisation in gelatin gel in the formation of mercuric carbonate.** F. M. SCHEMJAKIN and A. I. LAZAREVA (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 371—374).—The periodic crystallisation observed in the formation of  $HgCO_3$  from  $Na_2CO_3$  and  $HgCl_2$  in gelatin gel has been studied. The colour and form of the crystals are changed by reversing the inner and outer components.

O. D. S.

**Sensitisation of phosphatide sols by cholesterol in aqueous media.** H. G. B. DE JONG and N. I. JOUKOVSKY (Compt. rend. Soc. Biol., 1936, 123, 303—305).—Phosphatide sols with  $H_2O$  can be sensitised by cholesterol if the suspension is very fine and the temp. raised.

H. G. R.

**Film formation in a mixture of two hydrophilic sols: phosphatides and sodium nucleinate.** H. G. B. DE JONG and N. I. JOUKOVSKY (Compt. rend. Soc. Biol., 1936, 123, 511—516).—The nature of the film formed depends on the ionic concn. of the medium.

H. G. R.

**Moving-boundary method of measuring cataphoresis.** J. J. BIKERMAN (Trans. Faraday Soc., 1936, 32, 1648—1652).—The movement of the boundary between two almost identical sols of different colour is observed. Data are recorded for the boundary between an  $As_2S_3$  sol and a similar sol containing  $HgS$ .

E. S. H.

**Chemical constant and thermodynamic potential of nitric oxide gas and the gaseous equilibrium  $2NO + O_2 \rightleftharpoons 2NO_2$ , calculated from spectroscopic data.** H. ZEISE (Z. Elektrochem., 1936, 42, 785—789).—Theoretical.

E. S. H.

**Thermodynamics of endothermic processes of nitrogen fixation.** N. I. KOBOSEV, S. S. VASILIEV, and J. S. KASARNOVSKI (Acta Physicochim. U.R.S.S., 1936, 4, 245—262).—Equilibrium and energy relations have been calc. thermodynamically at 2000°, 3000°, and 3500° for the reactions  $0.5N_2 + 0.5O_2 = NO$  (a),  $0.5N_2 + CO_2 = NO + CO$  (b),  $0.5N_2 + 0.5H_2 + C = HCN$  (c),  $0.5N_2 + 0.5C_2H_2 = HCN$  (d), and  $0.5N_2 + CH_4 = HCN + 1.5H_2$  (e). The neglect of concomitant changes such as dissociation gives rise to serious errors, and the results obtained by Krase and Mackey (A., 1928, 1324) for (b) are considered to be incorrect. The reactions (c) and (d) give considerable yields of  $HCN$  and require little energy. The considerable yields of  $NO$  obtained in the glow discharge are connected with the low temp.

R. S. B.

**Displacement of equilibrium by substances which simultaneously act as catalytic accelerators. III.** N. SCHLESINGER (Acta Physicochim. U.R.S.S., 1936, 5, 79—92; cf. A., 1927, 837).—The equilibrium const. (*K*) in the reaction  $EtOH + AcOH \rightleftharpoons EtOAc + H_2O$  has been determined at 100° in presence of various salts and inorg. acids. In all (15) cases *K* decreases linearly with increase of salt concn. when the latter is expressed in millimol.

per mol. of  $\text{H}_2\text{O}$ . The displacement of equilibrium cannot be accounted for by ion hydration.

F. L. U.

**Dissociation equilibrium of sulphur trioxide.** A. F. KAPUSTINSKI and L. M. SHAMOVSKI (Acta Physicochim. U.R.S.S., 1936, 4, 791—802).—The equilibrium  $\text{SO}_3 \rightleftharpoons \text{SO}_2 + 0.5\text{O}_2$  has been studied at 850—1000° abs. in a static system containing a heated Pt wire. The data are expressed by  $\log (p_{\text{SO}_2})(p_{\text{O}_2})^{1/2}/p_{\text{SO}_3} = 5005/T + 4.743$ .  $\Delta S = 21.68$  g.-cal. per 1° and  $\Delta H = 22.88$  kg.-cal. per mol.

H. J. E.

**Evidence for the complete dissociation of salts at all concentrations in aqueous solutions.** W. H. BARNES (J. Chem. Educ., 1936, 13, 428—431).—A lecture.

L. S. T.

**Dissociation constants of different oxides in deuterium oxide.** G. SCHWARZENBACH, A. EPRECHT, and H. ERLÉNMEYER (Naturwiss., 1936, 24, 714).—The dissociation consts. of some weak acids and bases in  $\text{D}_2\text{O}$  (99.6%) have been determined potentiometrically. The normal potential of the  $\text{D}_2$  electrode is  $-0.0022$  volt, and the ionic product in  $\text{D}_2\text{O}$  (99.6%) is  $10^{-14.804}$  at 20°. The influence of  $\eta$  and the dielectric capacity on the dissociation const. is discussed.

A. J. M.

**Ionisation constant of acetic acid in dioxan-water mixtures.** H. S. HARNED and G. L. KAZANJIAN (J. Amer. Chem. Soc., 1936, 58, 1912—1915).—E.m.f. of the cells  $\text{H}_2$  (1 atm.)| $\text{AcOH}(m_1)$ ,  $\text{NaOAc}(m_2)$ ,  $\text{NaCl}(m_3)$ , dioxan- $\text{H}_2\text{O}$ | $\text{AgCl}$ - $\text{Ag}$  have been determined at 5° intervals from 0° to 50° in solutions containing 20, 45, and 70 wt.-% of dioxan. The ionisation const. of  $\text{AcOH}$ , calc. for the above temp. range, is in agreement with the empirical equation of Harned and Embree (A., 1935, 1321).

E. S. H.

**Anomalies in the dissociation constant of some halogenated organic acids.** M. BETTI and E. LUCCHI (Atti R. Accad. Lincei, 1936, [vi], 23, 465—469; cf. A., 1935, 564).—*o*-Chloro-, m.p. 162°,  $[\alpha]_D + 450.9^\circ$  in  $\text{C}_6\text{H}_6$ ,  $[M]_D + 1792^\circ$ , and *o*-bromo-, m.p. 123°,  $[\alpha]_D + 410.5^\circ$  in  $\text{C}_6\text{H}_6$ ,  $[M]_D + 1815^\circ$ , *cinnamylidenepheryl*- $\beta$ -hydroxynaphthylmethylamine have been prepared from the corresponding *cinnamaldehydes*, m.p. 56—57°, b.p. 138°/10 mm., and m.p. 67°, b.p. 160°/14 mm., respectively. The results indicate that the *o*- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{CH}:\text{CH}$  radical is more negative than the corresponding Br-radical. The dissociation consts. of the two halogenocinnamic acids are  $0.39 \times 10^{-4}$  and that of cinnamic acid  $0.365 \times 10^{-4}$ .

O. J. W.

**Solutions of aluminium fluoride.** V. CAGLIOTI (Gazzetta, 1936, 66, 549—551).—When  $\text{CaF}_2$  is dissolved in  $\text{AlCl}_3$  a complex F ion is formed. F.p. and electrolytic data for  $\text{AlF}_3$  solutions indicate that these probably contain the complex  $[\text{AlF}_6]'''$  ion.

O. J. W.

**Equilibrium between the trioxalatomanganate and dioxalatomanganate ions.** G. H. CARTLEDGE and W. P. ERICKS (J. Amer. Chem. Soc., 1936, 58, 2065—2069).—Extinction coeffs. of  $\text{K}[\text{Mn}(\text{C}_2\text{O}_4)_3]$  (I) and  $\text{K}[\text{Mn}(\text{C}_2\text{O}_4)_2(\text{H}_2\text{O}_2)]$  (II) in aq. solutions at various concns. have been determined in the visible region. (I) has max. absorption at about 520

m $\mu$  and (II) at about 450 m $\mu$ . Equilibrium between (I) and (II) is established almost instantaneously according to  $[\text{Mn}(\text{C}_2\text{O}_4)_3]''' + 2\text{H}_2\text{O} \rightleftharpoons [\text{Mn}(\text{C}_2\text{O}_4)_2(\text{H}_2\text{O}_2)]' + \text{C}_2\text{O}_4''$ ; the equilibrium const., determined spectrophotometrically, is  $3.8 \times 10^{-3}$  at 0°. Green and yellow forms of (II) give solutions with the same absorption curve; the solution probably contains an equilibrium mixture of *cis* and *trans* isomerides. The complex manganates may be derived from a covalent  $dsp^2$  structure, the fifth and sixth valency linkings being ionic or ion-dipole in character.

E. S. H.

**Effect of sugar alcohols and their anhydrides on the dissociation of boric acid.** J. C. KRANTZ, jun., C. J. CARR, and F. F. BECK (J. Physical Chem., 1936, 40, 927—931; cf. this vol., 289).—In general the anhydrides of sugar alcohols increase the dissociation of  $\text{H}_3\text{BO}_3$  < the sugar alcohols themselves, but the effect of erythritan is > that of erythritol or mannitol. Propylene glycol has no effect. The effect of  $\text{CO}(\text{CH}_2\cdot\text{OH})_2$  and glyceraldehyde is > that of glycerol.

J. W. S.

**Dynamics of the formaldehyde-hydrogen sulphite reaction.** A. SKRABAL and R. SKRABAL (Monatsh., 1936, 69, 11—41; cf. A., 1936, 684).—Redetermination of the equilibrium const. for the reaction  $\text{OH}\cdot\text{CH}_2\cdot\text{SO}_3' \rightleftharpoons \text{CH}_2\text{O} + \text{SO}_3\text{H}'$  has confirmed the accepted val. The reaction velocities have been measured and the results are discussed theoretically. They do not afford support for the "principle of microscopic reversibility."

F. L. U.

**Theory of binary solutions.** E. HÜCKEL (Z. Elektrochem., 1936, 42, 753—778).—A re-statement of thermodynamical principles on which Hückel's theory rests, with particular reference to solutions of long-chain mols.

E. S. H.

**Determination of activity coefficients from the potentials of concentration cells with transference. II. Hydrochloric acid at 25°.** T. SHEDLOVSKY and D. A. MACINNIS (J. Amer. Chem. Soc., 1936, 58, 1970—1972).—E.m.f. of the cells  $\text{Ag}, \text{AgCl}|\text{HCl}(c_1), \text{HCl}(c_2)|\text{AgCl}, \text{Ag}$ , where  $c_1 = 0.1N$  and  $c_2 = 0.003$ — $0.08N$ , have been determined. The activity coeffs. follow the Debye-Hückel theory with a distance of closest approach of 5.62 Å. up to about  $0.04N$ . At  $0.003$ — $0.1N$  accurate agreement with the Hückel equation is observed.

E. S. H.

**Thermodynamics of hydrochloric acid in dioxan-water mixtures from electromotive force measurements. I. Standard potentials.** H. S. HARNED and J. O. MORRISON (J. Amer. Chem. Soc., 1936, 58, 1908—1911).—E.m.f. of the cells  $\text{H}_2$  (1 atm.)| $\text{HCl}(m)$ , dioxan- $\text{H}_2\text{O}$ | $\text{AgCl}$ - $\text{Ag}$  have been determined at 5° intervals from 0° to 50° in solutions containing 20, 45, and 70% of dioxan and  $0.003$ — $0.2M$ - $\text{HCl}$ . The standard electrode potentials have been evaluated.

E. S. H.

**Activity and osmotic coefficients of aqueous solutions of lanthanum chloride at 25°.** C. M. MASON and G. L. ERNST (J. Amer. Chem. Soc., 1936, 58, 2032—2033).—The activity and osmotic coeffs. have been calc. from v.-p. data, determined by the isopiestic method.

E. S. H.

**Thermodynamic properties of fused salt solutions. IX. Lithium chloride in silver chloride.** E. J. SALSTROM, T. J. KEW, and T. M. POWELL (J. Amer. Chem. Soc., 1936, 58, 1848—1850).—E.m.f. of the cells  $\text{Ag}(s), \text{AgCl}$  in  $\text{LiCl}(l), \text{Cl}_2(g)$  have been determined at mol. fractions of  $\text{AgCl}$  from 1.000 to 0.136 and 500—635°. The activity, activity coeff., free energy of formation and of dilution, entropy, and heat of formation of  $\text{AgCl}$  at 500° and 600° have been calc. The activity, activity coeff., and partial mol. free energy of  $\text{LiCl}$  have been calc. from the Duhem relations. Positive deviations of the activities from ideality are discussed. E. S. H.

**Comminution and chemical affinity.** R. SCHENCK (Z. Elektrochem., 1936, 42, 747—752).—Published work on the influence of particle size on chemical equilibria is discussed. E. S. H.

**Significance of solubility product of very sparingly soluble salts.** E. LANGE and K. NAGEL (Z. physikal. Chem., 1936, 177, 321—330).—Theoretical. The relation between the solubility product,  $s$ , and the standard free energy of formation,  $K$ , and the e.m.f.,  $E$ , of a standard galvanic cell in which the salt is formed is given by  $K = -EF = ET \log_e s$ . If the concns. of the ions of the salt are large enough to be thermodynamically significant ( $> 10^{-10}N$ ), the usual calculations made by means of the solubility product principle are thermodynamically free from objection. When small concns. are involved, however, such calculations, whilst yielding vals. for electrode potentials in accord with experiment, have no theoretical significance, and in such cases the only theoretical basis for the calculation of electrode potentials is the above equation. R. C.

**Solubility relationships in mixtures of brassidic acid with erucic acid, methyl brassidate, and ethyl brassidate.** L. J. P. KEFFLER and A. M. MAIDEN (J. Physical Chem., 1936, 40, 905—917).—Determination of m.p. is to be preferred to the study of cooling curves in the determination of the phase-rule diagrams for mixtures of long-chain compounds. The binary systems of brassidic acid (I) with erucic acid (II), Me and Et brassidate are all simple eutectic systems. The solubility curves of (I) in the two esters are identical. The ideal solution law holds for (I) and (II), but not for systems containing the esters, which yield an S-shaped curve when  $\log N$  is plotted against  $1/T$ . The solubility of (I) in the esters is always less than the ideal solubility. All these compounds appear to exist in the simplest possible mols. in the liquid state, and no evidence could be obtained for the existence of a second cryst. form of any of them. J. W. S.

**Crystal chemistry. I. Graphic classification of binary systems.** C. W. STILLWELL (J. Chem. Educ., 1936, 13, 415—419).—In the classification adopted, crystal structure and other data are used to illustrate the influence of the properties of ions and atoms on the structure and properties of the crystals formed by their compounds. The binary systems are divisible into groups which include respectively the alloys, the ionic and at. compounds, and the mol. compounds. L. S. T.

**Thermodynamic calculation of the composition of binary compounds.** H. W. HERREILERS (Rec. trav. chim., 1936, 55, 921—924).—The  $p$ - $T$  diagram near a quadruple point is considered and the equilibrium has been calc. R. S.

**Water of crystallisation of certain complex salts and of nickel sulphate.** I. N. PLAKSIN (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 271—278).—Tensimetric measurements confirm the existence of  $\text{NiSO}_4 \cdot 1, 6$ , and  $7\text{H}_2\text{O}$ , but not of 3 and  $4\text{H}_2\text{O}$ , and establish the existence of  $\text{NiSO}_4 \cdot 2\text{H}_2\text{O}$ . Tensimetric data for the system  $\text{Cr en}_3\text{Cl}_3 \cdot \text{H}_2\text{O}$  at 25° suggest the formation of a dihydrate, and of a series of solid solutions of  $\text{H}_2\text{O}$  in the latter, whilst in the system  $(\text{NH}_4)_3[\text{Co}(\text{C}_2\text{O}_4)_3] \cdot \text{H}_2\text{O}$  a series of solid solutions of  $\text{H}_2\text{O}$  in the anhyd. salt and its pentahydrate are indicated. R. T.

**Dissociation pressure of crystal hydrates of variable composition.** B. A. MUROMTSEV (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 279—289).—Tensimetric data at 25° and 35° indicate that the systems  $[\text{Co en}_3\text{Cl}_3]_2, \text{CoCl}_2 \cdot \text{H}_2\text{O}$  and  $[\text{Pt}(\text{NH}_3)_4]\text{Cl}_2 \cdot \text{H}_2\text{O}$  consist of unbroken series of solid solutions. R. T.

**Static method for the determination of the equilibria of metals with carbon dioxide.** A. F. KAPUSTINSKI and A. SILBERMAN (Acta Physicochim. U.R.S.S., 1936, 4, 495—504).—A method is described by which equilibria of the type  $\text{M} + \text{CO}_2 = \text{MO} + \text{CO}$  can be investigated at const. pressure of  $\text{CO}_2$ . It is applied to the equilibrium between Sn and  $\text{CO}_2$  with results in agreement with those obtained by dynamic methods. The data correspond with  $0.5 \log K_p = 606.4/T - 1.1576$  from 600° to 1100°,  $\Delta F = 5546 - 10.587T$ , and  $\Delta H_0 = 5546$  g.-cal. O. D. S.

**Basic acetates of lead.** R. DUBRISAY and A. SAINT-MAXEN (Compt. rend., 1936, 203, 584—586).—The systems obtained on the addition of aq.  $\text{NH}_3$  or  $\text{NaOH}$  to  $\text{Pb}(\text{OAc})_2$  have been examined and evidence obtained for the existence of solid phases corresponding with  $(\text{OAc})_2[\text{Pb}_3\text{O}(\text{OH})_2]$  and  $\text{O}[\text{Pb}_3\text{O}(\text{OH})_2]$ . J. G. A. G.

**System magnesium sulphate-carbamide-water at 30°.** C. W. WHITTAKER, F. O. LUNDSTROM, and J. H. SHIMP (J. Amer. Chem. Soc., 1936, 58, 1975—1977).—Data for 30° show the solid phases  $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ ,  $\text{MgSO}_4 \cdot \text{CO}(\text{NH}_2)_2 \cdot 3\text{H}_2\text{O}$ , and  $\text{CO}(\text{NH}_2)_2$ . E. S. H.

**Equilibria in the system water-lithium chloride-ammonium chloride.** N. K. VOSKRESENSKAJA and O. K. JANATJEVA (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 291—293).—Equilibrium data are recorded. R. T.

**System bismuth iodide-rubidium iodide-water.** (MLLE.) M. L. DELWAULLE (Bull. Soc. chim., 1936, [v], 3, 1820—1822).—Data for 12° indicate the existence of the compounds,  $\text{BiI}_3 \cdot 3\text{RbI}$  and  $2\text{BiI}_3 \cdot 3\text{RbI}$ . J. W. S.

**System  $\text{K}_2\text{O}-\text{PbO}-\text{SiO}_2$ .** R. F. GELLER and E. N. BUNTING (J. Res. Nat. Bur. Stand., 1936, 17, 277—289).—The system has been examined by methods involving quenching, petrographic study, and, in certain cases, heating curves. The existence

of four ternary compounds with mol. ratios 1:2:2, 1:4:8, 1:1:4, and 2:1:3 has been established, and optical properties indicate the existence of a fifth. The fields of stability of the various unary, binary, and ternary compounds have been determined, and 14 quintuple invariant points located. D. C. J.

System alkali oxide- $\text{CaO-Al}_2\text{O}_3\text{-SiO}_2\text{-CO}_2$ . VI. Equilibria in the system  $\text{CaO-SiO}_2\text{-CO}_2$ . C. KROGER and K. W. ILLNER (Z. anorg. Chem., 1936, 229, 197-224; cf. A., 1936, 31).—Dissociation pressures of  $\text{CaCO}_3$  are unaffected by the presence of  $\text{Ca}_2\text{SiO}_4$ , but considerably increased by  $\text{Ca}_3\text{Si}_2\text{O}_7$ . Equilibria in the reaction  $2\text{Ca}_2\text{SiO}_4 + \text{CO}_2 \rightleftharpoons \text{Ca}_3\text{Si}_2\text{O}_7 + \text{CaCO}_3$  have been determined. Direct reaction occurs between  $\text{SiO}_2$  and  $\text{CaCO}_3$ , independent of the dissociation of the latter. Heats of reaction are calc. F. L. U.

Hydrolytic equilibria of calcium aluminate hydrates. E. P. VON POLHEIM (Mitt. zementtech. Inst. Tech. Hochsch. Berlin, 1935, 51, 45 pp.; Zement., 1935, 24, 643-648; Chem. Zentr., 1936, i, 142).—The limiting concns. of dissolved  $\text{CaO}$  and  $\text{Al}_2\text{O}_3$  permitting the stable existence of  $2\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 7\text{H}_2\text{O}$  (I), and  $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$  (II) in solution, are considered. According to the  $[\text{CaO}]$ , any consecutive pair of the substances  $\text{Al}(\text{OH})_3$ , (I), (II), and  $4\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot n\text{H}_2\text{O}$  may coexist as solid phase. The reactions of the anhyd. Ca aluminates with  $\text{H}_2\text{O}$  are discussed. J. S. A.

Complex formation involving weak acids. XVI. (a) Isotherms at  $18^\circ$  of the systems: sodium oxalate-copper (or zinc or magnesium) oxalate-water. (b) Solubility of copper, zinc, and magnesium oxalates in solutions of oxalic acid and sulphuric acid. (c) Potentiometric investigation of the complex anion,  $\text{Cu}(\text{C}_2\text{O}_4)_2^{2-}$ . H. T. S. BRITTON and A. A. MOSS. XVII. System sodium oxalate-thorium oxalate-water at  $25^\circ$ . H. T. S. BRITTON and M. E. D. JARRATT (J.C.S., 1936, 1489-1493, 1494-1495).—XVI.  $\text{M}^{14}\text{C}_2\text{O}_4\text{-Na}_2\text{C}_2\text{O}_4\text{-H}_2\text{O}$  mixtures have been studied at  $18^\circ$ . The solid components  $\text{Na}_2\text{Zn}(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$ ,  $\text{Na}_2\text{Mg}(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$  could not be isolated.  $\text{CuC}_2\text{O}_4$  and  $\text{ZnC}_2\text{O}_4$  are insol. in  $\text{H}_2\text{C}_2\text{O}_4$  but  $\text{MgC}_2\text{O}_4$  dissolves to form  $\text{Mg}(\text{HC}_2\text{O}_4)_2$ . The solubility product of  $\text{MgC}_2\text{O}_4$  has been calc. Evidence of the existence of  $\text{Cu}(\text{C}_2\text{O}_4)_2^{2-}$  has been obtained from potentiometric and analytical determinations.

XVII. Phase-rule studies show that  $\text{Na}_4\text{Th}(\text{C}_2\text{O}_4)_4 \cdot 6\text{H}_2\text{O}$  is stable only in presence of excess of  $\text{C}_2\text{O}_4^{2-}$ . R. S.

Addition compounds of phosphorous acid with certain organic compounds. H. L. REDFIELD and G. B. KING (J. Physical Chem., 1936, 40, 919-925).—The f.-p. diagrams for the binary systems of  $\text{H}_3\text{PO}_3$  with  $\text{AcOH}$ ,  $\text{CCl}_3\text{-CO}_2\text{H}$ ,  $\text{AcCO}_2\text{H}$ ,  $\text{PhOH}$ ,  $\text{COPhMe}$ , piperonal, and coumarin have been determined, but no compound formation is indicated. The solubilities at  $25^\circ$  of  $\text{PhOH}$ ,  $\text{H}_2\text{C}_2\text{O}_4$ , succinic and citric acid in aq.  $\text{H}_3\text{PO}_3$  of various concns. have been determined and compared with similar data for  $\text{H}_3\text{PO}_4$  (A., 1931, 922). Kendall's acidity rule holds for solutions, but not for f.-p. equilibria. The m.p. (corr.) of  $\text{H}_3\text{PO}_3$  is  $74.4^\circ$ . J. W. S.

Double decomposition in the absence of a solvent. XXIX. Stable complex of mutual systems. XXX. Representation of quinary complex mutual systems. V. P. RADISCHTSHEV (Ann. Sect. d'Anal., Physico-Chim., 1936, 9, 203-218, 219-253).—Theoretical. R. T.

(A) Representation of multicomponent systems. Spiral co-ordinates. (B) Representation of properties in ternary systems. Method of central and peripheral vectors. V. J. ANOSOV (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 5-25, 27-32).—Theoretical. R. T.

Equilibria in the saturated solutions of salts occurring in sea-water. II. Quaternary system  $\text{MgCl}_2\text{-CaCl}_2\text{-KCl-H}_2\text{O}$  at  $0^\circ$ . I. IGELSRUD [with T. G. THOMPSON] (J. Amer. Chem. Soc., 1936, 58, 2003-2009; cf. this vol., 429).—The solid phases occurring are  $\text{KCl}$ ,  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$ , and  $\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$ . The isotherm at  $0^\circ$  is characterised by the slight solubility of  $\text{KCl}$  or  $\text{MgCl}_2 \cdot \text{KCl} \cdot 6\text{H}_2\text{O}$  in solutions saturated with  $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ . E. S. H.

Heat of formation of the nitrogen molecule from atoms set free in the thermal decomposition of  $\text{Pt-N}$ . H. DAMIANOVICH and G. BERRAZ (An. Inst. Invest. cient. tecn., 1934, No. 3/4, 61-71).—The product formed by cathodic sputtering in a N atm. glows when heated quickly in air or vac., due to the formation of  $\text{N}_2$ . The heat of formation is approx. 150,000 g.-cal. H. J. E.

Specific heat, entropy, and heat of formation of iron carbide,  $\text{Fe}_3\text{C}$ . C. SCHWARZ and H. ULICH (Arch. Eisenhüttenw., 1936-1937, 10, 11-12, 91).—Calculations from published data give the heat content of  $\text{Fe}_3\text{C}$  at  $25.2^\circ$  as 4072 g.-cal. per mol., entropy 23.9 g.-cal. deg. $^{-1}$  per mol., and the free energy of formation from  $\alpha\text{-Fe}$  and  $\beta\text{-graphite}$  +2600 g.-cal. per mol. The heat contents for temp. between  $104.3^\circ$  and  $763.3^\circ$  are shown to agree closely with the experimental vals. A. R. P.

Hydrogen cyanide. IX. Conductivity of electrolytes in anhydrous hydrogen cyanide: some ammonium and tetra-alkylammonium salts at  $18^\circ$ . J. E. COATES and E. G. TAYLOR (J.C.S., 1936, 1495-1500; cf. this vol., 1341).—The conductivities of  $\text{NH}_4$ ,  $\text{NMe}_4$ , and  $\text{NEt}_4$  chloride, bromide, iodide, nitrate, and perchlorate, and of  $\text{NH}_4\text{CNS}$  and  $\text{NMe}_4$  picrate in  $\text{HCN}$  have been determined. The  $\text{NMe}_4$  and  $\text{NEt}_4$  compounds show large negative deviations from the Debye-Hückel-Onsager equation, but for  $\text{NH}_4$  compounds the agreement is good. R. S.

Electrolytic dissociation of  $\alpha\gamma\gamma$ -tetracyanopropene and  $\alpha\gamma\gamma$ -tetracyano- $\beta$ -methylpropene. Y. URUSHIBARA and M. TAKEBAYASHI (Bull. Chem. Soc. Japan, 1936, 11, 569-575).—According to conductivity and e.m.f. data the degrees of dissociation of  $\alpha\gamma\gamma$ -tetracyano-propene (I) and  $\beta$ -methylpropene (II) are shown to be comparable with the val. for  $\text{HCl}$ . (I) and (II) are strongly acidic and dissolve Zn, Mg, and Sn at room temp. The metallic salts resemble the corresponding chlorides in their solubility in  $\text{H}_2\text{O}$ . The solubilities of the Ag salts of (I) and (II) are respectively 0.1 and 0.388 g. per litre. In aq. solution

the dissociation is supposed to be directly attributable to the enimine form as represented by  
 $(\text{CN})_2\text{C}:\text{CH}:\text{C}(\text{CN})\text{:C}:\text{NH} \rightleftharpoons (\text{CN})_2\text{C}:\text{CH}:\text{C}(\text{CN})\text{:C}:\text{N}' + \text{H}'$   
 C. R. H.

**Electrical conductivity of glass-forming barium borate.** B. MARKIN and R. MÜLLER (*Acta Physicochim. U.R.S.S.*, 1936, 4, 471—480).— $\kappa$  data for fused mixtures (glasses) of  $\text{BaO} + \text{B}_2\text{O}_3$ ,  $\text{Na}_2\text{O} + \text{BaO} + \text{B}_2\text{O}_3$ , and  $\text{ZnO} + \text{B}_2\text{O}_3$  indicate bivalent cation movement where the amount of corresponding metallic oxide is large. In the expression  $\log_e \kappa = -A/T + B$ , where  $A$  and  $B$  are consts., the val. of  $A$  is increased by introducing Ba glasses into Na glasses. The energy of dissociation of the ions,  $E = 2AR$ , for Ba and Zn glasses is considered to be double that for the Na glasses.  
 C. R. H.

**High-frequency conductivity of colloidal electrolytes. II. Alkali and alkaline-earth caseinates.** G. SCHMID and A. V. ERKKILÄ (*Z. Elektrochem.*, 1936, 42, 781—785; cf. this vol., 1461).—The high-frequency effect is about twice as great for the alkaline-earth as for the alkali caseinates, but there is little difference between the individual members of each series. The charge of the cation appears to be the dominating factor. Published work on transport nos. in these solutions is discussed.  
 E. S. H.

**Use of the "skin" effect in the investigation of thin metallic layers.** J. GOLDFELD and N. I. KOBOSOV (*Acta Physicochim. U.R.S.S.*, 1936, 5, 243—270).—The variation of the high-frequency resistance  $R_H$  of thin layers of metals on a metal of different magnetic permeability  $\mu$  has been calc. In the case of Fe deposited on Pt or Ag,  $R_H$  reaches a max. after about 6 min. The influence of layer thickness and c.d. has been investigated. For a given thickness  $R_H$  depends on  $\mu$ , whilst  $\mu$  varies with the structure of the layer. The increase of  $\mu$  with time is attributed to the crystallisation of the layer. If the wire is heated in  $\text{H}_2$ , diffusion of Fe into the interior occurs and the rate of diffusion has been calc., but in air, all the Fe is oxidised. The diffusion of Zn in Fe has also been studied.  
 R. S.

**Absorption and dispersion of short electric waves in solutions of electrolytes in glycerol.** W. SCHMACKS (*Ann. Physik*, 1936, [v], 27, 285—298).—The dielectric const. and high-frequency conductivity of glycerol and glycerol solutions of  $\text{MgSO}_4$  of concn. from  $10^{-1}$  to  $10^{-3}$  g. per litre have been measured at  $\lambda\lambda$  from 10 to 20 m. A max. conductivity of  $\text{MgSO}_4$  has been observed at about 14 m.  
 O. D. S.

**Transfer resistance.** G. CHEN (*Sci. Rep. Nat. Univ. Peking*, 1936, 1, No. 3, 13—18).—A review.

**Gold and copper in salt crystals and synthetic sylvine.** M. J. BOGOMOLOVA (*Acta Physicochim. U.R.S.S.*, 1936, 5, 161—172).—The diffusion velocities of Au and Cu in NaCl and KCl have been studied and the ionic mobilities  $\mu$  determined, making use of the colouring action of electrons from a Na cathode.  $\mu$  is greater in KCl, and  $\text{Cu}^{++}$  is more mobile than  $\text{Au}^{+++}$  in each case, contrary to the order expected from the ionic diameters, whilst the plot of  $\log \mu$  against  $1/T$

is a straight line. When the crystal has been subjected to previous electron-colouring  $\mu$  is diminished owing to colloid formation.  
 R. S.

**Contact potential between fluid amalgam and mercury in a vacuum. I. Contact potential between sodium amalgam and mercury.** O. CHALTIKIAN and M. PROSKURNIN (*Acta Physicochim. U.R.S.S.*, 1936, 4, 263—274).—The contact potential between Hg and Na amalgam has been found to rise to an approx. const. val. of  $1.1 \pm 0.1$  volt at 0.025—0.09% of Na.  
 R. S. B.

**Platinum electrode. II. Adsorption properties of the platinum electrode.** A. SCHLIGIN, A. FRUMKIN, and V. MEDVEDOVSKI (*Acta Physicochim. U.R.S.S.*, 1936, 4, 911—928; cf. this vol., 1207).—The adsorption of  $\text{H}_2\text{SO}_4$ , HCl, HBr,  $\text{Na}_2\text{SO}_4 + \text{H}_2\text{SO}_4$ , NaCl + HCl, NaBr + HBr, NaCl + NaOH, NaBr + NaOH, and KOH at various potentials of the Pt electrode has been determined by  $p_H$  measurements. The results are compared with capacity measurements with the same electrode. Changes in the amount adsorbed on treating a  $\text{H}_2$ -saturated electrode with  $\text{O}_2$  and also on reducing an oxidised electrode by  $\text{H}_2$  are recorded.  
 H. J. E.

**Germanium. XVII. Electrochemical behaviour of germanium.** R. SCHWARZ, F. HEINRICH, and E. HOLLSTEIN (*Z. anorg. Chem.*, 1936, 229, 146—160; cf. this vol., 618).—The e.m.f. of Ge-calomel electrode combinations, using various aq. electrolytes, is neither const. nor reproducible unless  $\text{O}_2$  is excluded, and even in the latter event it is not exactly reproducible owing to variations in the surface condition. The normal potential  $\text{Ge}/\text{Ge}^{+++}$  cannot be determined by e.m.f. measurements in aq. solution. Ge can be determined electrolytically by deposition with Sn from alkaline oxalate solution.  
 F. L. U.

**Potential of platinum in solutions of silver salts.** A. OBRUTSCHEVA and A. FRUMKIN (*Compt. rend. Acad. Sci. U.R.S.S.*, 1936, 4, 11—13).—Bright Pt and Au in  $\text{AgNO}_3$  solution exhibit the potential of Ag in a few min. (cf. A., 1934, 257). Small platinised electrodes behave similarly although a much longer time is required. In this case the potential is at first (in the acidified solution) more positive than the Ag potential and changes in a direction opposed to that expected by an adsorption of  $\text{Ag}^+$ . Ag crystals are formed when the electrodes reach the val. of the reversible Ag potential, especially in the case of the platinised electrodes. Large platinised electrodes give a change of potential in the same direction, but do not reach the val. for the reversible  $\text{Ag}^+$  potential. When the large electrodes are agitated in the solution until a const. val. is reached the latter is no longer able to alter the potential of a new small electrode. A bright Pt electrode in this solution attained the Ag potential only after some hr. This solution recovered its original properties after warming with Ag powder at  $50^\circ$  or after strong illumination for many hr. These effects are not due to  $\text{Ag}^+$  adsorption, but to a small amount of a reducing substance in the Ag solution. This substance reduces the acids chemically bound to the Pt surface and then the separation of Ag results. A Ag ion of lower

valency ( $\text{Ag}_2^+$ ) is suggested as the electrochemically active material. D. C. J.

Periodic potential oscillations of iron in chromic-sulphuric acid solutions. III. M. KARSCHULIN (Z. Elektrochem., 1936, 42, 722—729; cf. A., 1934, 601, 1072).—Fe dissolves primarily as  $\text{Fe}^{2+}$ , which is subsequently oxidised to  $\text{Fe}^{3+}$  by  $\text{CrO}_3$ . The oscillations in the negative direction (with respect to a saturated  $\text{Hg}_2\text{Cl}_2$  electrode) occur when formation of  $\text{Fe}^{2+}$  and oxidation to  $\text{Fe}^{3+}$  are separated by a time interval in consequence of the diffusion layer at the Fe surface. The potential limits are then conditioned by the  $[\text{Fe}^{2+}]$  and the ratio  $[\text{Fe}^{2+}]/[\text{Fe}^{3+}]$  at the Fe surface. Oscillations in the positive direction occur when  $[\text{H}^+]$  in the neighbourhood of the Fe surface decreases so that  $\text{Fe}(\text{FeO}_2)_2$  is formed. The positive potential then reached is several hundred mv. < that of passive Fe in aq.  $\text{CrO}_3$ . E. S. H.

Meaning of diffusion potential. E. A. GUGGENHEIM (Phil. Mag., 1936, [vii], 22, 983—987).—The significance of diffusion potential in cells with liquid-liquid junctions is discussed. A. J. E. W.

Electromotive force of the cell  $\text{Zn-Hg}$  (2-phase)  $|\text{ZnSO}_4 (m) \text{ PbSO}_4 (s)|\text{Pb-Hg}$  (2-phase) and its temperature coefficient at  $25^\circ$  and concentrations from 0.05 to 1.5M. J. KIELLAND (J. Amer. Chem. Soc., 1936, 58, 1855—1857).—E.m.f. data and activity coeffs. of  $\text{ZnSO}_4$  are recorded. E. S. H.

Voltaic pile readily made from electrolytes. A. THIEL (Z. Elektrochem., 1936, 42, 742—744). Electrical effects produced by the contact of series of electrolytic solutions are described. E. S. H.

Passive metals in bimetallic electrode pairs. L. WOLF (J. pr. Chem., 1936, [iii], 147, 133—144; cf. this vol., 305, 582).—The use of one passive metal as reference electrode in the bimetallic electrode pairs employed in potentiometric titrations is described. This electrode is rendered passive by addition of a passivator, generally  $\text{NaNO}_3$  or  $\text{HNO}_3$ , to the solution to be titrated. The following electrode pairs have been tested;  $\text{Cr/Ag}$ ,  $\text{Cr/Hg}$ ,  $\text{Cr/Pt}$ ,  $\text{V2A alloy/Ag}$ ,  $\text{V2A/Hg}$ ,  $\text{V2A/Pt}$ . J. W. S.

Energy of electrolytic reduction of some substances with the atomic groups  $\text{C}\cdot\text{O}$  and  $\text{C}\cdot\text{C}$ . G. SEMERANO and A. CHISINI (Gazzetta, 1936, 66, 510—518).—The molar reduction potentials at a dropping Hg cathode of  $\text{CH}_3\text{Ph}\cdot\text{CH}\cdot\text{CHO}$ ,  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$ , and  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  dissolved in 0.1N- $\text{NH}_4\text{Cl}$  in 50% EtOH are  $-1.383$ ,  $-0.784$ , and  $-1.456$  volts, respectively. The two aldehydes are converted into the corresponding hydrobenzoin, and the acid is reduced to  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ . The relation between chemical constitution and molar reduction potential is discussed. O. J. W.

Colouring matters of *Drosera Whittakeri*. IV. Reduction potentials of some naphthaquinones. J. W. H. LUGG, A. K. MACBETH, and F. L. WINZOR (J.C.S., 1936, 1457—1462; cf. A., 1935, 623).—The normal reduction potentials,  $E_0$ , of 1:4-naphthaquinone, methylnaphthaquinone, lawsone, juglone, phthiocol, isonaphthazarin, methylnaphthazarin (I), naphthazarin, hydroxyjuglone, naphtha-

purpurin (II), hydroxydroserone (III) (natural and synthetic), and lomatiol have been determined by Fieser's method (A., 1935, 585). Fieser's conclusions relative to the additivity of  $E_0$  are confirmed. The results indicate that in (I), (II), and (III), the substituent is in the quinonoid ring. R. S.

Determination of decomposition potentials of fused salts. R. C. KIRK and W. E. BRADT (Trans. Electrochem. Soc., 1936, 70, Preprint 26, 317—326; cf. this vol., 430).—Decomp. potentials for fused alkali and alkaline-earth halides and certain other salts have been measured by the direct method. The depolarisation found by this method is cathodic rather than anodic and may be eliminated by the substitution of Pt for graphite cathodes. Vals. obtained by extrapolation to zero current with Pt cathodes are in good agreement with those given by the commutator method (cf. A., 1928, 135) and also with the calc. equilibrium reaction potentials. O. J. W.

Determination of decomposition potentials of fused salt mixtures containing tantalum oxide. R. C. KIRK and W. E. BRADT (Trans. Electrochem. Soc., 1936, 70, Preprint 27, 327—333).—The decomp. potential of  $\text{K}_2\text{TaF}_7$  in fused KCl (with and without the addition of  $\text{Ta}_2\text{O}_5$ ) is < that of fused KCl, and Ta is deposited. Measurements with 14 fused salts containing  $\text{Ta}_2\text{O}_5$  gave no decomp. potential corresponding with the Ta compound, and no Ta was deposited from these mixtures. It is suggested that current-potential diagrams obtained by the direct method may provide information relative to the behaviour of fused salt mixtures in electrodeposition. O. J. W.

Polarisation capacity of the mercury electrode. T. BORISSOVA and M. PROSKURNIN (Acta Physicochim. U.R.S.S., 1936, 4, 819—828).—The capacity of the double layer on Hg in  $\text{N-HCl}$ ,  $\text{-KCl}$ , and  $\text{-CsCl}$  first decreases with increasing negative polarisation, then increases to a max. at 0.4—0.5 volt, and finally passes through a min. at approx. 1.1 volt. The max. persists after careful purification and is attributed to a deformation or dehydration of the anion. The rise in the curve at high cathode polarisations is due to deformation of the cation. H. J. E.

Hydrogen overvoltage at high current densities. B. KARANOV (Acta Physicochim. U.R.S.S., 1936, 5, 193—200).—An apparatus for the determination of H overvoltages with c.d. up to 100 amp. per sq. cm. is described. The relation between overvoltage and log c.d. for Ag amalgam, Ag, and Pt is linear, in agreement with Volmer's theory. R. S.

Hydrogen overvoltage in non-aqueous solutions. I. S. LEVINA and M. SILBERFARB (Acta Physicochim. U.R.S.S., 1936, 4, 275—282).—H overvoltage ( $V$ ) on a Hg cathode has been determined for c.d.  $10^{-6}$ — $10^{-2}$  amp. per sq. cm. at  $25^\circ$  in 0.01—0.54N- $\text{HCl}$  in EtOH. For c.d. ( $i$ ) =  $10^{-6}$ — $10^{-3}$  amp. per sq. cm.,  $V = a + b \log i$ , where  $a$  and  $b$  are const., and  $b = 0.11$ — $0.12$ , in agreement with the theory of Erdey-Gruz and Volmer (A., 1930, 1376).  $V$  is independent of the duration of the experiment and of  $[\text{HCl}]$ , and is < for aq. solutions. R. S. B.

**Overvoltage.** G. CHEN (Sci. Rep. Nat. Univ. Peking, 1936, 1, No. 3, 1—11).—A review and discussion.

**Effect of pressure on the passivity of iron powder in alkali medium.** T. C. HUANG (J. Chinese Chem. Soc., 1936, 4, 406—412).—When the Fe powder in an Edison cell is packed under increasing pressure, the discharge potential shows a corresponding decrease in the passivity of the Fe. D. C. J.

**Passivity phenomena. XXX. Passivity phenomena at magnesium anodes in acid solutions.** W. J. MÜLLER and E. NACHTIGALL (Monatsh., 1936, 69, 1—10; cf. A., 1928, 713).—When Mg in the form of a protected electrode is anodically polarised at 3—12 volts in  $N\text{-H}_2\text{SO}_4$ , the current gradually falls to about  $\frac{1}{3}$  of its initial val. In the early stages the bright metal becomes covered with a black film, which breaks down and gives place to a matt grey surface. The latter is formed before the min. current is established, and persists during the period of passivity. By decreasing  $[\text{H}^+]$  at const.  $[\text{SO}_4^{2-}]$  the time required to attain passivity is slightly shortened. Mg also exhibits passivity in aq.  $\text{HNO}_3$ , but not in  $\text{HCl}$ .

**Polarographic studies with the dropping mercury electrode. IV. Influence of circuit resistance on maxima of current-voltage curves.** R. BRDIČKA (Coll. Czech. Chem. Comm., 1936, 9, 419—433; cf. this vol., 430).—The current max. obtained with 0.01N- $\text{Hg}_2(\text{NO}_3)_2$  in 0.005N- $\text{HNO}_3$  decreases as the resistance,  $R_e$ , external to the electrolyte is increased. Oscillographically recorded current-time curves for the formation of single drops show that the cathode is unpolarisable at  $<$  a sp. e.m.f. and yields large currents  $\propto$  the e.m.f. With o.m.f.  $>$  the sp. val., the Hg drop is polarised at all stages of growth. The polarisation increases linearly with e.m.f., so that the current always reaches the same val., corresponding with the "diffusion current." The discontinuous fall of current at a polarographic max. occurs at the same e.m.f. whatever the val. of  $R_e$  and is attributed to the polarisation of drops at the moment of formation. If  $R_e$  is increased, however, the drop becomes depolarised during growth unless the e.m.f. is sufficiently raised, in which case the diffusion current is always attained. J. G. A. G.

**Polarographic analysis in the study of keto-enol tautomerism.**—See this vol., 1488.

**Electrolysis of aqueous solutions of sodium and zirconyl sulphates.** I. W. E. BRADT and H. B. LINFORD (Trans. Electrochem. Soc., 1936, 70, Preprint 30, 363—371).—From these solutions Zr is deposited under certain conditions as a silver-white, compact, and adherent metal similar to Ni electroplate. This changes slowly to a non-adherent black powder, which may be Zr or some oxidation product. O. J. W.

**Conception of electrokinetics as an integral part of electrochemistry of solutions.** J. W. MCBAIN (Acta Physicochim. U.R.S.S., 1936, 4, 169—172).—The analogies between electrokinetic and electrolytic phenomena are discussed. The electrokinetic potential is regarded as having no real existence. R. S. B.

**Maximum yield of the intermediate product C in two successive bimolecular reactions, (I)  $A + B \rightarrow C$  and (II)  $A + C \rightarrow D$  when the constants  $k_1$  and  $k_2$  are known.** J. STUURMAN (Rec. trav. chim., 1936, 55, 934—936).—The calculation has been applied to the oxidation of thianthren by  $\text{AcO}_2\text{H}$  (cf. this vol., 1518). R. S.

**Chemical kinetics of dielectric relaxation.** F. C. FRANK (Trans. Faraday Soc., 1936, 32, 1634—1647).—Theoretical. The theory of unimol. chemical reaction velocities is applied to the process of change of orientation of a polar mol. in a substance showing dielectric loss and dispersion. Published data for different types of physical systems are discussed. E. S. H.

**Explosive limits of gaseous mixtures. I. Explosion limits of mixtures of hydrogen and air.** M. RIVIN and A. SOKOLIK (Acta Physicochim. U.R.S.S., 1936, 4, 301—316).—The conditions for initiating detonation waves have been investigated for  $\text{H}_2$ -air mixtures. The curve for explosion limit as a function of pressure and %  $\text{H}_2$  shows two min. which depend on energy of the igniting spark. With  $\text{H}_2$ - $\text{O}_2$  mixtures the curve for explosion limits has a min. at 100 mm. and 55%  $\text{H}_2$ . At 1 atm. explosion is possible between 23 and 85%  $\text{H}_2$ . The velocity of the explosion wave does not agree with theory, owing probably to dissociation in the front of the wave. The propagation and extinction of the flame and change in pressure have been studied in a long tube below the explosion limit for  $\text{H}_2$  and  $\text{O}_2$ . R. S. B.

**Effect of a chemically inert gas on the velocity of the chain reaction in mixtures of n-pentane and oxygen.** M. PRETTE (Compt. rend., 1936, 203, 561—563).—At 250—270°, near the lower inflammation limit of mixtures of 119—210 mm. of  $\text{O}_2$  and 119—209 mm. of  $\text{C}_5\text{H}_{12}$ ,  $\text{N}_2$  accelerates the reaction, but at 300—350°, near the upper limit of inflammation,  $\text{N}_2$  retards the reaction between 20—57 mm. of  $\text{C}_5\text{H}_{12}$  and 82—100 mm. of  $\text{O}_2$ . J. G. A. G.

**Inhibition by hydrogen of the chain reaction of mixtures of n-pentane and oxygen.** M. PRETTE (Compt. rend., 1936, 203, 619—620).—Addition of  $\text{H}_2$  (approx. 150—300 mm.) to a mixture of  $\text{C}_5\text{H}_{12}$  (50—308 mm.) and  $\text{O}_2$  (84—306 mm.) at 240—280° retards the slow oxidation and may prevent ignition. The  $\text{H}_2$  is most effective at 260—280°. H. J. E.

**Cold flames in mixtures of pentane and oxygen.** B. AIVAZOV and M. NEUMANN (Acta Physicochim. U.R.S.S., 1936, 4, 575—606; cf. this vol., 1344).—The conditions under which cold flames are propagated in mixtures of  $\text{C}_5\text{H}_{12}$  and  $\text{O}_2$  have been investigated. The pressure changes and change in composition of the gas during the induction period, the flame reaction, and the slow reaction which follows have been observed. Aldehydes and peroxides are formed in large amount during the flame reaction. The amounts of  $\text{CO}$  and  $\text{CO}_2$  formed are small. A slow autocatalytic reaction is observed outside the limits of the cold flame. O. D. S.

**Flame of carbon monoxide and oxygen. I. Influence of pressure on the intensity of visible**

radiation from the flame. H. KONDRATEEVA and V. KONDRATEEV (*Acta Physicochim. U.R.S.S.*, 1936, 4, 547—555).—The ratio of the intensity of blue light emitted to the no. of  $\text{CO}_2$  mols. formed per sec. in the combustion of CO in  $\text{O}_2$  has been measured between 11 mm. and 140 mm. It rises to a max. about 40 mm. and then decreases at higher pressures in a manner corresponding with the quenching of excited mols. with an efficiency of the order of 1. It is deduced that the preliminary increase corresponds with a change from a heterogeneous reaction at low pressures to a homogeneous reaction in which  $\text{CO}_2^*$  mols. are produced.

O. D. S.

Influence of a longitudinal electric field on the combustion processes in flames. A. E. MALINOVSKI and K. E. JEGOROV (*Acta Physicochim. U.R.S.S.*, 1936, 4, 929—936; cf. A., 1930, 424).—The retardation of the movement of flame in a  $\text{C}_2\text{H}_2$ -air mixture by means of an electric field is not a mechanical effect due to transport of neutral gas mols. by the charged particles. Negative ions play an important part in propagating flame. The effect of the field on the inner cone of a 25%  $\text{C}_2\text{H}_2$ -air flame is almost independent of the rate of supply of gas. The inner cone in flames of  $\text{CH}_4$  or heavy hydrocarbons in air is affected only by voltages approaching the breakdown voltage.

H. J. E.

Propagation of combustion along the surface of inflammable liquid. V. Effect of wind on velocity of propagation. I. T. KINBARA (*Bull. Inst. Phys. Chem. Res. Japan*, 1936, 15, 871—885).—Experimental results for EtOH-air flames are discussed.

J. S. A.

Propagation of combustion along [the] surface of inflammable liquids. VI. Effect of wind on the velocity of propagation. T. KINBARA (*Bull. Inst. Phys. Chem. Res. Japan*, 1936, 15, 1090—1104; see preceding abstract).—The effect of favourable as well as unfavourable winds in decreasing the velocity of flame propagation could not be explained by the change in appearance of a moving flame, nor by the lowering of surface temp. on EtOH caused by such winds.

R. C. M.

Kinetics of simultaneous polymerisation and ring formation. G. SALOMON (*Trans. Faraday Soc.*, 1936, 32, 1627—1628).—A reply to Stoll (this vol., 1073).

E. S. H.

Kinetics of thermal decomposition of methylamine. H. J. EMELEUS and L. J. JOLLEY (*J.C.S.*, 1936, 1524—1529; cf. A., 1935, 172, 1081).—The kinetics of the slow thermal decomp. of  $\text{NH}_2\text{Me}$  at 330—390°, and of the explosive oxidation at 400—600°, have been studied by a pressure change method. The rate of the slow reaction is given by an expression of the form  $v = Ae^{\phi}$ , where  $\phi = B'p^{0.83}e^{-15,000/T}$ . The crit. explosion pressure  $p_c$  is given by  $\log_e p_c/T = A'/T + B$  ( $A$ ,  $A'$ ,  $B$ ,  $B'$  are consts.). Results for the slow and explosive oxidations are correlated on the basis of the Semenov theory of degenerate chain reactions.

A. J. E. W.

Rate of oxidation of *o*-iodobenzoic acid by peracetic acid. J. BÖESEKEN and E. WICHERLINK (*Rec. trav. chim.*, 1936, 55, 936—940).—

50

*o*- $\text{C}_6\text{H}_4\text{I}\cdot\text{CO}_2\text{H}$  is oxidised by  $\text{AcO}_2\text{H}$ , the unchanged  $\text{AcO}_2\text{H}$  destroyed by  $\text{NaOH}$  and a trace of  $\text{CuO}$ , and the  $\text{IO}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  formed determined by  $\text{KI}-\text{Na}_2\text{S}_2\text{O}_3$ .  $E$  and  $B$  in the equation,  $\log K = B - E/2.303RT$ , for this reaction are 15,920 and 7.9, respectively,  $k$  being about  $10^{-4}$  at 20°.

R. S. C.

Prototropy in relation to exchange of hydrogen isotopes. II. Comparison of the velocities of dissociation of a proton and a deuteron from a  $\nu$ -acid. C. L. WILSON (*J.C.S.*, 1936, 1550—1553; cf. this vol., 1344).—The rate of ionisation of 2-*o*-carboxybenzylindan-1-one (I) and its 2-deutero analogue (II) have been studied indirectly by observing the rate of bromination in aq.  $\text{AcOH}$  containing  $\text{NaOAc}$ . The first-order velocity coeff. for (I) is several times that for (II), the observed difference corresponding with a difference in the activation energies of 0.9 kg.-cal., in accord with the estimated difference of crit. energy of approx. 1 kg.-cal.

A. J. E. W.

Kinetics of certain bimolecular reactions in solution. E. A. MOELWYN-HUGHES (*Acta Physicochim. U.R.S.S.*, 1936, 4, 173—224).—A crit. review.

R. S. B.

Kinetics of oxidation of ferrous ion by nitrous acid. E. ABEL, H. SCHMID, and F. POLLAK (*Monatsh.*, 1936, 69, 125—143; cf. A., 1930, 1128).—Oxidation of  $\text{Fe}^{2+}$  by  $\text{HNO}_2$  takes place by means of concurrent reactions between  $\text{Fe}^{2+}$  and  $\text{HNO}_2$ ,  $\text{Fe}^{2+}$ ,  $\text{HNO}_2$ , and  $\text{H}^+$ , and  $\text{Fe}^{2+}$  and  $\text{NO}_2$ , the last-named being related to the  $\text{HNO}_2$  and  $\text{NO}$  present. Velocity coeffs. of the above reactions have been determined at 25° using a wide range of concns. The mechanism of the opposing reaction between  $\text{Fe}^{3+}$  and  $\text{NO}$  is discussed.

F. L. U.

Kinetics of sulphonium compounds. I. N. HELLSTROM (*Z. physikal. Chem.*, 1936, 177, 337—354; cf. A., 1932, 26).—The rate of formation in aq. solution at 25° of sulphonium salts by reaction of alkyl- and aryl-substituted thioglycolic acids and sulphide di-acids with  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$ ,  $\text{CH}_3\text{I}\cdot\text{CO}\cdot\text{NH}_2$ , and  $\alpha$ - and  $\beta$ -iodopropionic acid has been measured. The velocity,  $v$ , is small in acid solution, but increases with the degree of neutralisation; in neutral solution the reaction is bimol. and exhibits a salt effect,  $v$  falling with  $[\text{Na}^+]$ .  $\text{OH}^-$  ions have little or no effect on  $v$ .  $\text{CO}_2\text{H}$  and  $\text{Ph}$  in the reacting mols. retard the reaction. In some cases the sulphonium salt decomposes into alcohol and sulphide compound.

R. C.

Mechanism of elaidinisation reaction.—See this vol., 1488.

Mechanism of aromatic side-chain reactions.—See this vol., 1497.

Reaction kinetics and the Walden inversion.—See this vol., 1487.

Kinetics of adsorption of hydrogen and of deuterium by platinum. E. B. MAXTED and C. H. MOON (*J.C.S.*, 1936, 1542—1546).—The initial adsorption of  $\text{H}_2$  and  $\text{D}_2$  on Pt follows the equation  $\log a/(a-x) = kt^n$  ( $a$ =saturation capacity,  $x$ =vol. adsorbed after time  $t$ ).  $nk$ , expressing the rate of adsorption, is approx. 1.5 times as great for  $\text{H}_2$  as for  $\text{D}_2$  in the temp. range  $-79^\circ$  to  $50^\circ$ . The approxi-

ation of this ratio to the square root of the ratio of the masses of  $D_2$  and  $H_2$ , and the low activation energy (approx. 2500 g.-cal.), suggest control of the process by diffusion to the internal surface. A. J. E. W.

**Evaporation of nickel in a vacuum.** G. BRYCE (J.C.S., 1936, 1517—1518).—The rate of evaporation of Ni in a vac. has been determined for the temp. range 1250—1450° abs. by colorimetric determination of the Ni evaporated from a hot filament. The v.p. of Ni is given by  $\log_{10}(cp) = 9.148 - 2.00 \times 10^4/T$  ( $c$ —condensation coeff.). A. J. E. W.

**Wicke's reaction.** W. BOTTGER and E. THOMA (J. pr. Chem., 1936, [ii], 147, 11—21).—The time required for the production of blackening on  $Ni(OH)_2$  over which a mixture of moist  $SO_2$  and  $O_2$  (or air) is passed has been studied for  $Ni(OH)_2$  prepared and treated in different ways, for different  $[SO_2]$ , and for different temp. The effect is attributed to the formation of  $Ni(OH)_3$  through the action of a relatively stable intermediate product with a peroxide-like O-linking in the  $SO_2$ - $O_2$ - $H_2O$  mixture. J. W. S.

**Rate of absorption of oxygen by sodium sulphite solution.** W. S. E. HICKSON (Nature, 1936, 138, 645).—Stirring the interior of a solution of  $N-Na_2SO_3$  without disturbing the surface decreases the rate at which  $O_2$  is absorbed by 48% compared with the unstirred solution. L. S. T.

**Absorption velocity of sulphur dioxide by sodium iodide.** I. HIGUTI (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 1105—1116).—Measurements of v.p. and composition of solid phase confirmed the existence of  $3NaI \cdot 8SO_2$  and  $NaI \cdot 4SO_2$  described by Foote and Fleischer (A., 1931, 799). The rate of absorption at 0° and -21° agreed with the expression  $\log s/(s-x) = Kt^n$  previously found applicable in other cases (cf. this vol., 561). R. C. M.

**Kinetics of the sulphite process.** A. J. COREY and O. MAASS (Canad. J. Res., 1936, 14, B, 336—345).—The delignification of wood chips and meal in H sulphite solutions at 100—140° follows an approx. unimol. law, deviations being probably due to the colloidal nature of lignin and the submicroscopic structure of the wood. The energy of activation is 21,000 g.-cal. per g.-mol. The influence of pressure has been studied at 5—10 atm., using an atm. of  $N_2$ . Increase of pressure above 7 atm., the v.p. of the H sulphite solution, has no influence on the rate of delignification or quality of the product. R. S. B.

**Thermal decomposition of calcium carbonate.** A. OLIVERIO (Rend. Sem. Fac. Sci. R. Univ. Cagliari, 1934, 4, 119—121; Chem. Zentr., 1936, i, 521).—The decomp. in an air stream of 2 litres per hr. in a tube 15 mm. wide was 1.67% in 56 hr. at 420° and was almost complete in 200 hr. at 620°. H. J. E.

**Influence of form of intermediate phases on the velocity of the reduction of iron oxide by hydrogen.** G. TSCHUFAROV and B. AVERBUCH (Acta Physicochim. U.R.S.S., 1936, 4, 617—635).—The velocity of reaction of natural cryst. magnetite and hæmatite with  $H_2$  has been measured at intervals of 20° from 300° to 700°. The change in porosity during reduction was followed and the structure at

different stages of the reaction investigated by X-ray analysis. The reaction appears to be autocatalytic.  $Fe_3O_4$  is present at all stages of incomplete reduction.  $FeO$  is not observed. From 300° to 500° the porosity is independent of  $T$  and determined by the degree of reduction. Above 500° the porosity decreases rapidly with  $T$ , whilst the size of the crystals of  $\alpha$ -Fe increases. The temp. coeff. of the reaction is normal up to 550° and low above this temp. The activation energy is calc. to be 16,500 g.-cal. for magnetite and 19,500 g.-cal. for hæmatite below 550°.

O. D. S.

**Kinetics of dissolution of alkali borate glasses.** R. L. MÜLLER (Acta Physicochim. U.R.S.S., 1936, 4, 99—118; cf. this vol., 1074).—Previous work is reviewed. The rate-determining process in the case of alkali borate glasses in which the mol. fraction of  $M_2B_4O_7$  is  $< 0.5$  occurs at the surface.  $H_2O$  is first adsorbed by the surface ions, which then become fully hydrated and go into solution. The energy of activation is 10—15 kg.-cal. The results are discussed in relation to current theories of dissolution and evaporation. R. S.

**Elementary processes in the formation of metal oxide from metal and oxygen, and in related reactions.** C. WAGNER (Angew. Chem., 1936, 49, 735—740).—The diffusion processes responsible for the propagation of heterogeneous reactions of the type indicated through the compact boundary layer of compound are reviewed with reference to the author's published work. Diffusing species may be: (a) Ions, wandering by migration to empty lattice positions or between-lattice positions. In compounds with non-stoichiometric composition (e.g.,  $FeO$ ,  $Cu_2O$ ), the former mechanism operates, as shown by the rise in ionic conductivity at high temp. with the excess of O. (b) Electrons, in compounds of semi-metallic character. Where ions of variable valency occur (e.g.,  $Cu_2O$ ), these may propagate points of electron-deficit. Velocity of reaction is conditioned by the slower of the two diffusion processes, (a) or (b). The theory is applicable also to the solid reactions of silicate and spinel formation, in which the small cations are the diffusive species. J. S. A.

**Catalytic action of hydrogen on carbon monoxide flame.** H. J. WALLS (Trans. Faraday Soc., 1936, 32, 1495—1501).—When the infra-red radiation on explosion of  $CO-O_2$  mixtures containing  $H_2$  is plotted against the initial pressure of the reactants, a step occurs in the curve at pressure  $p_s$  (cf. A., 1929, 973).  $p_s$  rises with temp., and is thus not a lower ignition limit.  $p_s$  is probably the pressure at which two combustion mechanisms are equally rapid, these involving probably an O atom or thermal chain, and a H atom chain, respectively. Effects on the step produced by heating the reaction vessel are ascribed to removal of H atoms by the walls. A. J. E. W.

**Catalytic influence of chromic sulphate on the speed of decomposition of chromic acid by heat, when dissolved in sulphuric acid of varying concentration.** H. C. S. SNETHLAGE (Rec. trav. chim., 1936, 55, 874—880; cf. this vol., 1073).—The decomp. of  $CrO_3$  in aq.  $H_2SO_4$  is catalysed by  $Cr_2(SO_4)_3$ , the effect decreasing as  $[H_2SO_4]$  is increased and

becoming negative when  $[H_2SO_4]$  is  $>95\%$ . The results are in agreement with the theory that decomp. involves a bimol. and a unimol. reaction, the velocity coeffs. of which have been calc. R. S.

**Decomposition of alkaline-earth carbonates in aqueous solution on boiling.** B. L. VANZETTI and A. OLIVERIO (Rend. Sem. Fac. Sci. R. Univ. Cagliari, 1934, 4, 112—118; Chem. Zentr., 1936, i, 521).—The decomp. is influenced by the presence of Cu and Ni salts. H. J. E.

**New catalytic behaviour of mercuric salts.** I. G. TRAVAGLI (Gazzetta, 1936, 66, 525—528).— $Hg^{II}$  salts dissolved in  $H_2SO_4$  or  $H_3PO_4$  are able to catalyse the conversion of nitriles into amides. The catalytic behaviour has been investigated in detail for the conversion of  $(CN)_2$  into  $(CO\cdot NH_2)_2$ . O. J. W.

**Reducing action of mercury. III. Hydrogen peroxide formation and the copper-catalysed autoxidation of quinquivalent molybdenum and other strong reductants in acid solution.** W. M. MURRAY, jun., and N. H. FURMAN (J. Amer. Chem. Soc., 1936, 58, 1843—1847; cf. this vol., 1353).—Reduction by Hg may be used for the determination of Fe, V, or Mo, as these ions decompose catalytically any  $H_2O_2$  formed. For micro-determinations  $O_2$  must be excluded.  $Mo^V$  is autoxidised rapidly in presence of small amounts of Cu. A mechanism for this and similar reactions is discussed. E. S. H.

**Acid catalysis in non-aqueous solvents. III. Rearrangement of N-iodoformanilide in anisole solution.** R. P. BELL and J. F. BROWN (J.C.S., 1936, 1520—1524).—The rearrangement of  $HCO\cdot NIPh$  into  $HCO\cdot NH\cdot C_6H_4I\cdot p$  in PhOMe solution is a unimol. reaction catalysed by  $H^+$ . The reaction has been studied in presence of 8 org. acids, for which the catalytic consts. ( $\alpha$ ) are given approx. by  $\alpha=3.63K_d^{0.21}$  ( $K_d$ =dissociation const. in  $H_2O$ ). A side reaction occurs with production of I. A. J. E. W.

**Influence of some colloids on the velocity of inversion of sucrose.** S. BERLINGOZZI and M. TESTONI (Annali Chim. Appl., 1936, 26, 366—369; cf. B., 1931, 134; this vol., 35).—The velocity of inversion of sucrose in aq. citric acid is lowered by lyophilic and by metallic colloids. L. A. O'N.

[Organic catalysts.] W. LANGENBECK and F. BAEHREN (Ber., 1936, 69, [B], 2406; cf. this vol., 589).—A reply to Eistert (this vol., 844). H. W.

**Hydrocatalase.** R. RETOVSKY (Bull. Soc. Chim. biol., 1936, 18, 1106—1114).—The kinetics of the decomp. of  $H_2O_2$  by certain mineral waters shows that two processes, a catalase action and auto-decomp., are involved. The decomp. is dependent on  $p_H$ , and the activity decreases with time. A. L.

**Oxidation of glucose.**—See this vol., 1491.

**Relative catalytic activity of several metals for the isotopic interchange reaction,  $H_2O+HD\rightarrow HDO+H_2$ .** K. HIROTA and J. HORIUTI (Sci. Papers Inst. Phys. Chem. Res. Tokyo, 1936, 30, 151—168; cf. this vol., 162, 163, 430, 684).—The interchange series (order of catalytic activity) is Pt (sp. catalytic activity  $k=5\times 10^{-1}$  at  $0^\circ$ )  $>$  Ni ( $7\times 10^{-2}$  at

$100^\circ$ )  $>$  Fe ( $3\times 10^{-4}$  at  $100^\circ$ )  $>$  Cu ( $2\times 10^{-3}$  at  $180^\circ$ )  $>$  Au ( $3\times 10^{-4}$  at  $180^\circ$ )  $>$  Ag ( $1\times 10^{-4}$  at  $180^\circ$ ). No activity for Hg could be established. The parallelism between this series and that for H atom recombination, overvoltage, and hydrogenation catalysis is pointed out. The results for Pt suggest that in all cases the rate of reaction is determined by the genuine interchange. R. C. M.

**Autoxidation of chromite solutions.** F. HEIN and O. STUMM (J. pr. Chem., 1936, [ii], 147, 53—59).—The oxidation of suspensions of  $Cr(OH)_3$  in aq. KOH, when shaken with  $O_2$  or air, has been studied for various  $[KOH]$  and in presence of various catalysts. The best activators for conversion into  $CrO_4^{--}$  are  $Mn(OH)_2$ ,  $Cu(OH)_2$ ,  $Mn(OH)_2+Cu(OH)_2$ , and amalgamated Cu+liquid Hg. Possible mechanisms of the action are discussed. J. W. S.

**Oxidation of ferrous sulphate solutions.** J. R. POUND (J.S.C.I., 1936, 55, 327—330r).—The catalytic action of Pt-black, NO, and activated C in the oxidation of aq.  $FeSO_4$  was confirmed. Numerous other substances examined gave negative results. The reaction in presence of NO is bimol. with respect to  $FeSO_4$  and unimol. with respect to NO. The dependence of the rate of oxidation on concn., time, surface of solution, and dissolved  $O_2$  was studied. Aq.  $FeSO_4$  is oxidised rapidly by  $HNO_3 > 0.5N$ . H. J. E.

**Method of investigating catalyst surfaces.** B. JEROFEEV and K. MOCHALOV (Acta Physicochim. U.R.S.S., 1936, 4, 859—860).—On admitting air to a tube containing Fe filings reduced *in situ* at  $450^\circ$  the resistance increased greatly and the tube functioned as a coherer for Hertz waves. Fe containing 1% of  $Al_2O_3$  as a promoter did not lose its capacity for acting as a coherer after 46 hr. reduction at  $450^\circ$ . The Fe surface is coated with an  $Al_2O_3$  film which is not reduced under these conditions. H. J. E.

**Catalytic decomposition of ammonia.** I. CHRISMAN (Acta Physicochim. U.R.S.S., 1936, 4, 899—910).—The kinetics of the decomp. of  $NH_3$  on a  $Fe-Al_2O_3-K_2O$  catalyst at  $300-450^\circ$  were studied by a flow method. The activation energies for the temp. ranges  $300-350^\circ$  and  $350-450^\circ$  were 12.4 and 39.7 kg.-cal. per g.-mol., and were attributed to the formation and decomp. of nitride. H. J. E.

**Mechanism of the arresting action of the promoter on the reduction of the iron ammonia catalyst.** N. I. KOBOSEV (Acta Physicochim. U.R.S.S., 1936, 4, 829—840).—Data for the effect of  $Al_2O_3$ ,  $K_2O$ ,  $KF$ ,  $BeO$ , and  $MgO$  on the rate of reduction of  $Fe_3O_4$  and  $FeO$  by  $H_2$  are discussed (cf. B., 1936, 629). The promoter forms a surface film which protects the Fe oxide from reduction, and also favours the formation of small crystals of Fe. H. J. E.

**Oxidation of carbon. II.** J. D. LAMBERT (Trans. Faraday Soc., 1936, 32, 1584—1591; cf. this vol., 434).—The secondary conversion of CO into  $CO_2$  in the combination of C occurs more rapidly at a pure C surface than at a surface of C containing Fe. C treated with Mn behaves similarly to C treated with Fe on oxidation at  $400^\circ$ , but without secondary oxidation of CO to  $CO_2$ . The mechanism is discussed.

Possibly the primary reaction product is a gaseous complex similar to  $C_3O_2$ . E. S. H.

**Selective combustion of hydrogen, carbon monoxide, and methane by palladium catalysts.** M. S. PLATONOV and O. V. NEKRASSOVA (Z. anal. Chem., 1936, 106, 416—418).—A Pd catalyst on a ceramic carrier, prepared by reduction of  $PdCl_2$  with  $H_2$  at 120—140°, burns  $H_2$  catalytically at room temp., CO at 140—150°, and  $CH_4$  at 400—450°. The selective combustion of  $H_2$  in presence of CO is not possible; such mixtures are burned at 150°, and the composition is calc. from the vol. contraction. J. S. A.

**Interaction of carbon disulphide and sulphur dioxide.** B. CRAWLEY and R. H. GRIFFITH (Trans. Faraday Soc., 1936, 32, 1623—1626).—A survey of a wide range of catalysts for the reaction has been made. Interaction appears to occur by collision of a free  $CS_2$  mol. with an adsorbed  $SO_2$  mol. Activated adsorption of only one reactant is necessary. E. S. H.

**Hydrogenation with hydrogen dissolved in palladium.** D. DOBITSCHIN and A. FROST (Acta Physicochim. U.R.S.S., 1936, 5, 111—130; cf. A., 1935, 940).—The hydrogenation of  $C_2H_4$ ,  $CH_2:CHEt$ , and  $C_2H_2$  by H absorbed in sputtered films of Pd has been followed by measuring the electrical resistance of the films, which varies with the H content. With  $C_2H_4$  and  $CH_2:CHEt$  the reaction is more rapid than the desorption of H at  $-78^\circ$ . The rate of hydrogenation of  $C_2H_4$  by  $H_2$  dissolved in Pd is  $>$  when it is in the gas phase. Ageing of the Pd film leads to parallel decrease of catalytic activity and of the rate of absorption of  $H_2$ . F. L. U.

[Catalytic] synthesis of benzine.—See B., 1936, 1028.

**Catalyst poisoning from the point of view of the specificity of active centres.** III. Relative durations of sojourn of *n*-propyl alcohol and propaldehyde molecules, and true energy of activation of *n*-propyl alcohol dehydrogenation on copper. A. BORK and A. A. BALANDIN. IV. Orientation of molecules of reactants and resultants on catalyst surface in catalysed dehydrogenations and analogous catalytic reactions. A. BORK (Z. physikal. Chem., 1936, B, 33, 435—442, 443—458).—III. The rate of dehydrogenation of  $PrOH$  to  $EtCHO$  on Cu at 252° and the influence on the velocity of  $EtCHO$  may be represented by  $dm/dt = k(M-m)/N$ , where  $k$  contains no adsorption coeffs. (cf. this vol., 1076). The durations of sojourn on the catalyst and the heats of adsorption of  $PrOH$  and  $EtCHO$  are equal over a temp. range of 40°. The true energies of activation of the dehydrogenation of  $EtOH$  and  $PrOH$  are both 12,200 g.-cal. The logarithmic relation between the consts. of Arrhenius' equation (cf. *ibid.*, 435) holds.

IV. Existing experimental data and theoretical reasoning indicate that the rate of catalytic dehydrogenation and similar catalyses is given by  $dm/dt = k(M-m)/M$ , where  $M$  is the no. of mols. of reactant entering the reaction tube and  $m$  the no. of mols. reacting in unit time, and  $k$  contains no adsorption coeffs. Homologous reactants have the same energy of activation. If two homologous reactants undergo

dehydrogenation at the same rate, and if for one the adsorption coeffs. of reactant and resultant are equal, this is true of the other also, and for each reaction the duration of sojourn on the catalyst of reactant and resultant is the same. A method of determining relative adsorption coeffs. is described. R. C.

**Catalytic conversion of natural gas into carbon monoxide and hydrogen.**—See B., 1936, 1075.

**High-pressure hydrogenation of low-temperature tar.** V. Molybdenum catalysts.—See B., 1936, 1075.

**Twitchell's reagent as promoter of esterification.**—See this vol., 1487.

**Kinetics of the process at the iron anode of a galvanic element.** V. ROITER and V. JUSA (Acta Physicochim. U.R.S.S., 1936, 4, 135—144).—The results of polarisation determinations can be expressed by  $\Delta\epsilon = abI/(1+bI)$ , where  $\epsilon$  is the potential and  $I$  the c.d. By analogy with the Langmuir equation it is suggested that the potential decrease is due to the adsorption of a substance of which the concn. in the electrolyte  $\propto$  c.d. R. S.

**Electrolytic oxidation.** VIII. Apparent reducing properties of an anode. A. HICKLING (J.C.S., 1936, 1453—1456).—The ratio of the vols. of  $O_2$  and  $H_2$  evolved during electrolysis of acid solutions of  $KMnO_4$  and  $K_2Cr_2O_7$  has been determined under varying conditions of c.d. and concn., and with different acids present. This ratio is abnormally large, the discrepancy being attributed to formation of  $H_2O_2$  from  $OH^-$  discharged at the anode, and subsequent reaction of this with the  $KMnO_4$  or  $K_2Cr_2O_7$ . A. J. E. W.

**Production of electrolytic zinc.**—See B., 1936, 1100.

**Electrolytic refining of aluminium.**—See B., 1936, 1100.

**Theory of electrolytic chromium plating.** I.—See B., 1936, 1044.

**Electrochemical protection of metallic surfaces.**—See B., 1936, 1044.

**Formation of carbon dendrites.** H. THIELE (Nature, 1936, 138, 688).—Further experiments illustrating the reduction of graphitic acid at a cathode and the formation of dendrites are described (cf. this vol., 1089). L. S. T.

**Mechanism of catalytic interchange of hydrogen with water and alcohol.** J. HORIUTI and G. OKAMOTO (Trans. Faraday Soc., 1936, 32, 1492—1494; cf. this vol., 430).—The rate-determining step for the electrode process at a polarised Ni-H electrode is the atomisation of the  $H_2$  mol. on the metal. A homopolar Ni-H linking is assumed. The application of this result to the Pt-H electrode process is discussed. A. J. E. W.

**Chemical activity of the rare gases.** VII. Action of helium on bismuth under the influence of electrical discharges at low pressure. H. DAMIANOVICH (An. Inst. Invest. cient. tecn., 1934, No. 3/4, 20—22; Chem. Zentr., 1936, i, 497).—He was combined with Bi in a discharge at 1—2 mm.

pressure. The product contained 4.5 c.c. of He per g. of Bi.

H. J. E.

**Cathodic platinum obtained in a hydrogen atmosphere.** H. DAMIANOVICH and C. CHRISTEN (An. Inst. Invest. cient. tecn., 1934, No. 3/4, 72—75; Chem. Zentr., 1936, i, 498).—No evidence of compound formation was found.

H. J. E.

**Thermal decomposition of reversible and irreversible systems forming a gas phase.** I. Cathodic platinum oxide and chemically produced platinum oxyhydrate. II. Platinum-helium and platinum-nitrogen compounds and the systems reduced platinum, electrolytic platinum, and carbon. J. PIAZZA and H. DAMIANOVICH (An. Inst. Invest. cient. tecn., 1934, No. 3/4, 32—45, 46—56; Chem. Zentr., 1936, i, 497—498).—I. The Pt oxide obtained by cathodic sputtering in an O<sub>2</sub> atm. is identical in its thermal decomp. and X-ray pattern with that obtained from H<sub>2</sub>Pt(OH)<sub>6</sub>, and resembles the Pt-N and Pt-He compounds in its decomp. curve and autocatalytic phenomena.

II. The Pt-He and Pt-N compounds produced in a discharge undergo irreversible thermal decomp. The decomp. is compared with that in Pt-O and C-air systems.

H. J. E.

**Reaction kinetics in electric discharges.** S. S. VASSILIEV, N. I. KOBOSEV, and E. N. ERJEMIN (Acta Physicochim. U.R.S.S., 1936, 5, 201—242).—The following discharge reactions have been subjected to kinetic analysis: the oxidation of N<sub>2</sub>, the formation of O<sub>3</sub> and H<sub>2</sub>, and the cracking of CH<sub>4</sub>. The relation between the actual yield and the limiting energy yield and the influence of the power of the discharge are discussed.

R. S.

**Effect of temperature on photochemical formation of ozone.** A. EUCKEN and F. PATAT (Z. physikal. Chem., 1936, B, 33, 459—474; cf. A., 1924, ii, 159).—The formation of O<sub>3</sub> from O<sub>2</sub> at 20—50 mm. by ultra-violet light of  $\lambda$  chiefly 1720 Å. (Al spark) has been examined. Assuming that the mechanism is  $O_2 + h\nu \rightarrow 2O$ ,  $O + O_2 + M \rightarrow O_3 + M$ ,  $O_3 + O \rightarrow 2O_2$  it may be shown that at equilibrium  $[O_3] = k[O_2]^2$  and that the position of equilibrium is independent of the intensity of radiation. Both deductions are confirmed by experiment. The variation of  $k$  with temp. gives  $6160 \pm 100$  g.-cal. per mol. for the energy of activation of  $O + O_3 \rightarrow 2O_2$ . From the results  $[O_3]$  at various heights in the atm. has been calc., the results showing that the effective O<sub>3</sub> layer is at a height of  $\leq 40$  km.

R. C.

**Effect of light on the ignition of monosilane-oxygen mixtures.** H. J. EMELEUS and K. STEWART (Trans. Faraday Soc., 1936, 32, 1577—1584).—SiH<sub>4</sub>, Si<sub>2</sub>H<sub>6</sub>, and Si<sub>3</sub>H<sub>8</sub> absorb light of  $\lambda\lambda$  <1850, <1980—2020, and <2140—2190 Å., respectively. SiH<sub>4</sub> mixed with Hg vapour is decomposed by the 2537 Å. Hg resonance line, giving H<sub>2</sub> and solid polymerised SiH<sub>x</sub> ( $x < 0.9$ ). Light from an Al spark or Hg resonance arc causes explosion of SiH<sub>4</sub>-O<sub>2</sub> mixtures at temp. < the normal range for thermal ignition. SiH<sub>4</sub>-O<sub>2</sub> mixtures at pressures > the crit. explosion pressure undergo slow oxidation on exposure to the Hg resonance arc. The reaction has

an induction period and in the initial stages follows the law  $\Delta p = ke^{kt}$ , which characterises hydrocarbon combustion.

E. S. H.

**[Photochemical] reduction of ferric salts by organic acids.** P. LAL and P. B. GANGULY (Z. anorg. Chem., 1936, 229, 16—18).—Reduction of aq. solutions of pure normal Fe<sup>III</sup> citrate and tartrate by light from a quartz Hg lamp follows a zero-mol. course. The quantum yield ( $\lambda$  546 m $\mu$ ) is 0.5 for the citrate and 0.62 for the tartrate. The reaction is strongly catalysed by traces of Th, U, Cu, and Zr salts in the decreasing order given.

F. L. U.

**Action of various elements and compounds on photographic plates.** III. S. AOYAMA, T. FUKUROI, and K. SUZUKI (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 923—936; cf. A., 1935, 47, 1087).—Physical factors are considered.

J. S. A.

**Latent images below the threshold.** LUPPO-CRAMER (Phot. Korr., 1935, 71, 137—138; Chem. Zentr., 1936, i, 942).—A strong Becquerel effect occurs in AgI-gelatin plates if an I acceptor is present and physical development is used. The absence of the effect in AgBr dry plates is ascribed to the fact that unilluminated AgI is relatively much more sensitive to blue light than is AgBr.

H. J. E.

**Destruction of latent images and desensitisation by dyes.**—See B., 1936, 1131.

**Photochemical reactions of iron gluconates.** R. NEIGER and P. NEUSCHUL (Z. physikal. Chem., 1936, 177, 355—364).—Fe<sup>II</sup> gluconate (I) in aq. solution is oxidised in the dark under the influence of atm. O<sub>2</sub> to a Fe<sup>III</sup> salt (II) of unknown constitution, which is stable in the dark. Fe<sup>III</sup> gluconate (III) is stable in the dark in air. In an O<sub>2</sub>-free atm. (I) and (III) are stable in the dark. In daylight (II) and (III) are reduced to a Fe<sup>II</sup> salt, which from the solution of (II) separates as a solid (IV). Invert sugar delays the appearance of (IV). (III) is reduced more readily if O<sub>2</sub> is excluded. These reductions are apparently genuine photochemical reactions. Fe<sup>II</sup> mannionate behaves similarly to (I).

R. C.

**Photochemical peroxide formation.** IV, V.—See this vol., 1489, 1492.

**Initiation of gas reactions by ions.** II. **Hydrogen-chlorine mixtures.** P. GUNTHER and K. HOLM (Z. physikal. Chem., 1936, B, 33, 407—434).—Investigation of the induction of reaction in a H<sub>2</sub>-Cl<sub>2</sub> mixture, by allowing N ions to diffuse into it, has confirmed results previously reported (A., 1934, 975). Each ion initiates  $\sim 2.5$  reaction chains, which shows that the chemical action of the ions is approx. the same whether they are introduced into the reaction mixture by diffusion or produced *in situ* by  $\alpha$ -particles or X-rays. The mobility of Cl ions in moist Cl<sub>2</sub> is greatly reduced by the addition of a small amount of H<sub>2</sub>, suggesting that in presence of H<sub>2</sub> HCl is formed in the immediate vicinity of the ions and, dissolving in H<sub>2</sub>O, associates itself with the ion and so slows it down. Hence the formation of HCl under the influence of ions occurs during the life of the ions, not at their neutralisation. The no. of reaction chains initiated by an ion appears to be

independent of the life of the ion. Following Lind's cluster theory it may be supposed that the electrostatic fields of the N ions cause  $\text{Cl}_2$  mols. to become associated with them, and some of these are so distorted as to give Cl atoms, which start the reaction. The present experiments indicate that  $\alpha$ -particles initiate reactions by their electrostatic action on the ions to be excited. R. C.

**Enrichment of the light argon isotopes by diffusion.** H. BARWICH and W. SCHÜTZE (*Naturwiss.*, 1936, 24, 667).—An enrichment of  $^{36}\text{Ar}$  and  $^{38}\text{Ar}$  by diffusion into a current of Hg vapour has been observed. A. J. M.

**Action of atomic hydrogen on inorganic compounds.** H. KROEPFELIN and E. VOGEL (*Z. anorg. Chem.*, 1936, 229, 1—15; cf. A., 1935, 730).—Observations on the action of  $\text{H}_2$  containing about 14% of H on 86 solid inorg. elements and compounds are recorded. The experiments were conducted at room temp., but in some cases considerable local rise of temp. was observed. With a few substances luminescence was produced. Generally, compounds of heavy metals are reduced readily. The action is, however, sometimes only superficial, owing either to catalysis of H by the reaction products, or to impermeability of the latter to H. Alkali metal salts are reduced to metal when the anion is destroyed by H (e.g.,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{CN}^-$ ,  $\text{ClO}_3^-$ ). Films of gelatin and of Cellophane are impermeable to H. Aq. solutions of  $\text{AgNO}_3$ ,  $\text{HgCl}_2$ , and  $\text{Cu}(\text{OAc})_2$  are reduced to metal,  $\text{CrO}_4^{2-}$  and  $\text{MnO}_4^-$  in acid solution to  $\text{Cr}^{3+}$  and  $\text{Mn}^{2+}$ ,  $\text{I}_2$  to  $\text{I}^-$ ,  $\text{H}_2\text{O}_2$  to  $\text{H}_2\text{O}$ , and methylene-blue and indigotin in  $\text{H}_2\text{SO}_4$  to leuco-compounds. Working details are given. F. L. U.

**Influence of combustion conditions on the density of water formed from commercial hydrogen and oxygen.** W. H. HALL and H. L. JOHNSTON (*J. Amer. Chem. Soc.*, 1936, 58, 1920—1922).—The vol. ratio  $\text{H}_2:\text{O}_2$  has no significant influence on the  $d$  of the  $\text{H}_2\text{O}$  produced when reaction occurs in a flame, but the  $d$  may be affected by several p.p.m. if combination takes place over a Pt catalyst. When  $\text{O}_2$  is in excess  $d$  may be low, probably by reason of the lower reaction velocities of the higher isotopes of O. With excess of  $\text{H}_2$ ,  $d$  may be high, owing to incomplete exchange between steam and excess of  $\text{H}_2$ . E. S. H.

**Isotopic interchange reaction between chloroform and water.** J. HORIUTI and Y. SAKAMOTO (*Bull. Chem. Soc. Japan*, 1936, 11, 627—628).—The isotopic interchange between  $\text{CHCl}_3$  and  $\text{D}_2\text{O}$  in alkaline solution proceeds more quickly than the decomp. In neutral or acid solution the interchange is much slower. C. R. H.

**Sodium fluorenone as a dehydrating agent.** H. E. BENT and H. M. IRWIN, jun. (*J. Amer. Chem. Soc.*, 1936, 58, 2072—2073).—Na fluorenone has a higher efficiency than  $\text{Mg}(\text{ClO}_4)_2$  or activated  $\text{Al}_2\text{O}_3$ . E. S. H.

**Thermal dissociation and absorption spectra of vapours of  $\text{KNO}_2$ ,  $\text{KNO}_3$ ,  $\text{NaNO}_3$ , and  $\text{AgNO}_3$ .** K. BUTKOV and V. TSCHASSOVENNI (*Acta Physicochim. U.R.S.S.*, 1936, 5, 137—159).—The products

obtained by heating  $\text{NaNO}_3$ ,  $\text{KNO}_3$ ,  $\text{KNO}_2$ , and  $\text{AgNO}_3$  in an evacuated quartz tube have been studied spectrographically in the range 7000—1880 Å. Vapours of the complete mol. are present in all except  $\text{NaNO}_3$ .  $\text{KNO}_3$  gives NO at temp.  $> 550^\circ$ , and  $\text{NO}_2$  on cooling.  $\text{KNO}_2$  behaves similarly, except that on cooling NO persists and no  $\text{NO}_2$  is formed.  $\text{AgNO}_3$  gives  $\text{NO}_2$  only at  $270^\circ$ . The mols. are not ionised in the vapour state. Bond linking energies are calc., that corresponding with the semipolar  $\text{N}\rightarrow\text{O}$  linking being 92 kcal. per mol. F. L. U.

**Active oxides. CIII. Course of reactions in which solid substances take part.** G. F. HUTTING (*Monatsh.*, 1936, 69, 42—74; cf. this vol., 1216 and previous abstracts).—A summary of the author's work on reactions involving metal oxides is given. The reactions are classified under 11 main types, and the characteristics of each are described. F. L. U.

**Theory of corrosion phenomena. V. Application of the pore theory of corrosion to the phenomenon of the difference effect of Thiel and Eckell.** W. J. MULLER and E. LOW. VI. Determination of the metal potential of a working anode and of the potential and resistance requisite for local cells. W. J. MULLER (*Z. Elektrochem.*, 1936, 42, 789—792, 830—833; cf. this vol., 940).—V. Published work is reviewed in the light of Muller's theory.

VI. The determination of potential at two different c.d. through the pores is described. Published results are discussed. E. S. H.

**Corrosion of metals by water and carbon dioxide under pressure.**—See B., 1936, 1098.

**Influence of sodium chloride and hydrogen peroxide in rapid corrosion experiments.**—See B., 1936, 1098.

**Etching of copper by oxygen.** C. F. ELAM ([MRS.] C. F. TIPPER) (*Trans. Faraday Soc.*, 1936, 32, 1604—1614).—The etching effect obtained by heating Cu in vac. is due to the presence of  $\text{Cu}_2\text{O}$ ; it can be reproduced by oxidising the surface and appears to be due to attack by  $\text{O}_2$  along crystal planes, especially [100] and [110]. The relation between the orientation of the Cu crystal and the  $\text{Cu}_2\text{O}$  formed has been investigated. E. S. H.

**Copper peroxide and nascent copper oxide.** E. JUSTIN-MUELLER (*Bull. Soc. chim.*, 1936, [v], 3, 1913—1915).—Addition of  $\text{H}_2\text{O}_2$  to slightly alkaline aq.  $\text{CuSO}_4$  yields a brownish-yellow colour apparently due to  $\text{CuO}_2$ .  $\text{Cu}(\text{OH})_2$  in presence of aq.  $\text{CuSO}_4$  has a slight oxidising effect on tincture of guaiacum, with reduction to  $\text{Cu}_2(\text{OH})_2$ . J. W. S.

**Compounds of copper salts with tertiary amines.**—See this vol., 1395.

**Combination of magnesium chloride and magnesium methoxide.** (Mlle.) M. L. QUINET (*Bull. Soc. chim.*, 1936, [v], 3, 1823—1829).—Action of Mg on a conc. solution of  $\text{MgCl}_2$  in MeOH, of  $\text{Mg}(\text{OMe})_2 \cdot 2\text{MeOH}$  on  $\text{MgCl}_2$  in MeOH, or of  $\text{MgCl}_2 \cdot 6\text{MeOH}$  on a conc. solution of  $\text{Mg}(\text{OMe})_2$  in MeOH, gives the cryst. compound  $\text{MgCl}_2 \cdot 3\text{Mg}(\text{OMe})_2 \cdot 11\text{MeOH}$ . E. W. W.

**Formation of magnesium oxysulphate.** (MLLE.) M. L. DELYON (Bull. Soc. chim., 1936, [v], 1811—1817).—MgO dissolves in conc. aq.  $\text{MgSO}_4$  (>500 g. per litre) at  $80^\circ$ , and then gradually gives a ppt. which after 24 hr. has the const. composition  $\text{MgSO}_4 \cdot 3\text{MgO} \cdot 11\text{H}_2\text{O}$ . (I) The ppt. from solutions containing <300 g. of  $\text{MgSO}_4$  per litre is  $\text{Mg}(\text{OH})_2$ , whilst solutions of intermediate concn. yield a mixture of  $\text{Mg}(\text{OH})_2$  and (I). Attempts to prepare (I) from  $\text{Mg}(\text{OH})_2$  were unsuccessful but it was pptd. by addition of NaOH to aq.  $\text{MgSO}_4$  at  $80^\circ$ . J. W. S.

**Generating media of montmorillonite and sepiolite.** J. DE LAPPARENT (Compt. rend., 1936, 203, 553—555).—Montmorillonite is probably formed by devitrification of a glass in a medium containing Mg. Sepiolite (this vol., 957) results from direct action of Mg salt solutions on siliceous gels.

J. G. A. G.

**Existence of zinc metaborate.** R. TOURNAY (Compt. rend., 1936, 203, 558—560).—Heat is evolved at  $580$ — $630^\circ$  and at  $775$ — $820^\circ$  when the temp. of an equimol. mixture of  $\text{B}_2\text{O}_3$  and  $\text{ZnO}$  is slowly raised.  $2\text{B}_2\text{O}_3 \cdot 3\text{ZnO}$  is formed at  $>700^\circ$ , but the existence of  $\text{B}_2\text{O}_3 \cdot \text{ZnO}$  is denied.

J. G. A. G.

**Cadmium suboxides and subhalides.** R. E. HEDGER and H. TERREY (Trans. Faraday Soc., 1936, 32, 1614—1616).—X-Ray examination shows that the so-called subhalide prepared by dissolving Cd in molten  $\text{CdCl}_2$  is a mixture of  $\text{CdCl}_2$  and Cd; the so-called suboxide formed by treating the above with  $\text{H}_2\text{O}$  is a mixture of  $\text{CdO}$  and Cd. The solubility of Cd in  $\text{CdCl}_2$  at  $570$ — $810^\circ$  has been determined.

E. S. H.

**Oxidation of metals. IV. Oxide film on aluminium.** G. D. PRESTON and L. L. BIRCUMSHAW (Phil. Mag., 1936, [vii], 22, 654—665; cf. A., 1935, 1469; this vol., 569).—The oxide film found on Al at room temp. was isolated by removing the metal by treatment in HCl gas at  $250^\circ$ . Electron diffraction photographs show that the film is amorphous. Crystallisation begins slowly on heating at  $680^\circ$ , but not at temp. up to  $650^\circ$ . The film becomes a random mass of small crystals of cubic  $\gamma\text{-Al}_2\text{O}_3$  as found on the surface of molten Al.

N. M. B.

**Reaction aluminium oxide-carbon-chlorine.** N. M. STOVER and C. CONSTANTINESCU (Canad. J. Res., 1936, 14, B, 328—335).—The reaction between  $\text{Al}_2\text{O}_3$ , C and  $\text{Cl}_2$  has been studied at  $644$ — $880^\circ$ , using varying proportions of  $\text{Al}_2\text{O}_3$  and C, and static and streaming  $\text{Cl}_2$ .  $\text{O}_2$  was present in the reaction product, suggesting that the main reaction is  $2\text{Al}_2\text{O}_3 + 6\text{Cl}_2 = 4\text{AlCl}_3 + 3\text{O}_2$ , the role of the C being primarily catalytic. For a given ratio  $\text{Al}_2\text{O}_3 : \text{C}$  the ratio  $\text{CO}_2 : \text{O}_2$  in the gaseous product increased with the wt. of solid mixture. CO was obtained in the static experiments, but not with streaming  $\text{Cl}_2$ . The temp. at which  $\text{AlCl}_3$  first sublimed decreased with decreasing ratio  $\text{Al}_2\text{O}_3 : \text{C}$ . Less C was consumed, in many experiments, than that required to form  $\text{CO}_2$  with the O of the  $\text{Al}_2\text{O}_3$ . Using  $\text{WO}_3$  instead of  $\text{Al}_2\text{O}_3$ ,  $\text{O}_2$  and good yields of  $\text{CO}_2$  were formed with streaming  $\text{Cl}_2$  (cf. Sears and Lohse, A., 1935, 834).

R. S. B.

**Preparation and properties of indium dichloride.** J. K. AIKEN, J. B. HALEY, and H. TERREY (Trans. Faraday Soc., 1936, 32, 1617—1622).—The prep. of  $\text{InCl}_2$  and its analogies with  $\text{SnCl}_2$  in physical properties and lattice structure are described.  $\text{InCl}_2$  and  $\text{SnCl}_2$  appear to be associated in the solid state.

E. S. H.

**Disappearance of carbon monoxide in presence of electrically heated nickel filaments.** G. BRYCE (J.C.S., 1936, 1513—1517).—When a Ni filament is heated to above  $1200^\circ$  abs. in CO at low pressure in a bulb at  $-190^\circ$ , the CO disappears rapidly and completely, but can be recovered by heating the bulb. The action is slow at room temp., and negligible at  $100^\circ$ . The CO is removed by evaporated Ni as it condenses on the bulb, 2 mols. of CO being removed per atom of Ni, probably with formation of a subcarbonyl. This absorbs more CO on gentle warming. CO was also adsorbed by Ni freshly condensed in a bulb in a vac. Hot Ni does not affect  $\text{CO}_2$  or  $\text{N}_2$  under similar conditions. Mo at temp.  $>1900^\circ$  abs. removes CO in a similar manner.

A. J. E. W.

**Physical and chemical properties of liquid hydrogen phosphide (diphosphine,  $\text{P}_2\text{H}_4$ ).** P. ROYEN and K. HILL (Z. anorg. Chem., 1936, 229, 97—111; cf. this vol., 440).—The limiting  $d$  of the vapour of liquid H phosphide, purified by fractionation at a low temp., corresponds with the formula  $\text{P}_2\text{H}_4$ . No indication of the existence of higher homologues in the product of the action of aq. KOH on P has been observed. The v.-p. curve of  $\text{P}_2\text{H}_4$  has been determined between  $-70^\circ$  and  $10.8^\circ$  and is expressed by a two-const. formula. B.p. by extrapolation  $=51.7^\circ$ ; mean mol. heat of vaporisation between  $-25^\circ$  and  $-8^\circ = 7890$  g.-cal.; m.p.  $-99^\circ$ .  $\text{P}_2\text{H}_4$  is decomposed by HCl even at temp.  $<$  m.p., and there is no evidence for the existence of a hydrochloride. The decomp. is expressed by  $3\text{P}_2\text{H}_4 = 2\text{P} + 4\text{PH}_3$ , the solid product consisting of a yellow modification of P with adsorbed  $\text{PH}_3$ . The proportion of the latter varies with the state of division of the solid.

F. L. U.

**Partly halogenated phosphines. Formation of so-called solid hydrogen phosphide, particularly of its phenyl derivatives.** P. ROYEN and K. HILL (Z. anorg. Chem., 1936, 229, 112—128; cf. preceding abstract).—Attempts to isolate  $\text{PH}_2\text{X}$  ( $\text{X}=\text{Cl}, \text{Br}$ ) by the action of Br,  $\text{PBr}_5$ ,  $\text{PCl}_5$ , or  $\text{HCl} + \text{AlCl}_3$  on  $\text{PH}_3$  have been unsuccessful. Compounds of the type  $\text{PHRX}$  cannot be isolated owing to their rapid conversion into  $\text{PX}_3$  and  $\text{PH}_3\text{RX}$ . By condensation of  $\text{PPh}_2\text{Cl}$  with  $\text{PH}_3$  a yellow product containing 42% of adsorbed Ph phosphines is obtained, resulting from the decomp. of  $\text{P}_2\text{H}_6\text{Ph}_2$ . Me and Ph derivatives of " $\text{P}_{12}\text{H}_6$ " described in the lit. are not compounds, but adsorbates of Me and Ph phosphines on yellow amorphous P.

F. L. U.

**New oxide of phosphorus.** P. W. SCHENK and H. PLATZ (Naturwiss., 1936, 24, 651).—If a mixture of  $\text{P}_2\text{O}_5$  vapour and  $\text{O}_2$  is passed through a hot discharge tube (pressure about 1 mm.) a bluish-violet product separates in the cool part of the tube immediately behind the discharge zone. This substance

liberates I from KI, and may be preserved for a day at room temp. in the absence of  $\text{H}_2\text{O}$ . It is considered to contain 2% of a new peroxide,  $\text{PO}_3$  (or  $\text{P}_2\text{O}_6$ ).

A. J. M.

**Preparation and properties of some lower acids of phosphorus.** I, II. V. N. OSIPOV (J. Gen. Chem. Russ., 1936, 6, 933—940, 941—946).—I. The acid mixture formed when colourless P is oxidised by air in  $\text{H}_2\text{O}$  (3—6 days, 10—15°) has been investigated. The mixture and Mg salts give no crystals. Metallic Mg yields  $\text{Mg}_2\text{H}_2\text{P}_2\text{O}_7 \cdot 11\text{H}_2\text{O}$ , which differs from the known  $\text{Mg}_2\text{P}_2\text{O}_6 \cdot 12\text{H}_2\text{O}$  since it loses  $\text{H}_2\text{O}$  at 105° more slowly, dissolves in 25%  $\text{H}_2\text{SO}_4$  more slowly and with evolution of gas, becomes brown when treated with  $\text{AgNO}_3$ , etc.  $\text{AgOAc}$  in dil.  $\text{AcOH}$  converts the new salt into  $\text{Ag}_4\text{H}_2\text{P}_2\text{O}_7$ , different from  $\text{Ag}_4\text{P}_2\text{O}_6$  since it evolves  $\text{H}_2$  when heated in  $\text{CO}_2$ . The reaction between Mg and  $\text{Na}_2\text{H}_2\text{P}_2\text{O}_6 \cdot 6\text{H}_2\text{O}$  in dil.  $\text{AcOH}$  produces  $\text{Mg}_2\text{P}_2\text{O}_6$ ,  $\text{Mg}_2\text{H}_2\text{P}_2\text{O}_7 \cdot 13\text{H}_2\text{O}$ , which is converted by  $\text{AgNO}_3$  into brown  $\text{Ag}_4\text{P}_2\text{O}_6$ ,  $\text{Ag}_4\text{H}_2\text{P}_2\text{O}_7$ .

II. When P undergoes oxidation by air in  $\text{H}_2\text{O}$  for a longer time than in the above experiments, the  $\text{H}_4\text{P}_2\text{O}_6$ , which presumably is the first reaction product, reacts with  $\text{H}_2\text{O}$ :  $\text{H}_4\text{P}_2\text{O}_6 + \text{H}_6\text{P}_2\text{O}_7 \rightarrow \text{H}_8\text{P}_2\text{O}_8$ ; the usual equation  $\text{H}_4\text{P}_2\text{O}_6 + \text{H}_2\text{O} = \text{H}_3\text{PO}_3 + \text{H}_3\text{PO}_4$  may be incorrect. After 2—3 weeks the acid mixture and Mg give  $\text{MgHPO}_4$ ,  $\text{MgH}_2\text{PO}_4 \cdot 5.5\text{H}_2\text{O}$  (I), after 4 weeks  $3\text{MgHPO}_4$ ,  $\text{MgH}_2\text{PO}_4 \cdot 10\text{H}_2\text{O}$  (II) is produced. Both (I) and (II) evolve  $\text{H}_2$  when heated in  $\text{CO}_2$ .  $\text{AgNO}_3$  changes the colour of (I) to yellow  $\rightarrow$  brown  $\rightarrow$  black, the colour of (II) to greenish-yellow black. (I) is insol. in  $\text{H}_2\text{O}$  and is not pptd. by  $\text{Th}(\text{NO}_3)_4$  in dil.  $\text{HNO}_3$ . It is converted by  $\text{AgNO}_3$  in neutral solution into  $\text{Ag}_{11}\text{H}_3\text{P}_4\text{O}_{16}$  (brown), in dil.  $\text{AcOH}$  into  $\text{Ag}_{10}\text{H}_3\text{P}_4\text{O}_{16}$  (yellow), and in dil.  $\text{H}_2\text{SO}_4$  into  $\text{Ag}_8\text{H}_5\text{P}_4\text{O}_{16}$  (brown). (II) and  $\text{AgNO}_3$  afford in neutral solution  $\text{Ag}_{11}\text{H}_3\text{P}_4\text{O}_{16}$ , a brown ppt.

J. J. B.

**Phosphates. IV. Pyrophosphates of some bivalent metals and their double salts, and solid solutions with sodium pyrophosphate.** H. BASSETT, W. L. BEDWELL, and J. B. HUTCHINSON (J.C.S., 1936, 1412—1429).—The pyrophosphates  $\text{M}_2\text{P}_2\text{O}_7 \cdot x\text{H}_2\text{O}$  ( $\text{M} = \text{Mg}, \text{Mn}, \text{Co}, \text{Ni}, \text{Cu}, \text{Zn}$ , and  $\text{Cd}$ ) have been studied.  $x$  may have the vals. 8, 7, 6.5, 6.25, 6, 5, 4.2, 4, 3.3, 3.6, 3.25, 3, 2.3, or 2.1, the whole series of hydrates not being found with any one metal. Such "parent" hydrates give solid solutions or definite double salts with  $\text{Na}_4\text{P}_2\text{O}_7$ , these probably being formed by replacement of  $[\text{M}(\text{H}_2\text{O})_4]^{++}$  by  $[\text{Na}_2(\text{H}_2\text{O})_6]^{++}$ , or  $[\text{M}(\text{H}_2\text{O})_4]^{++}$  by  $\text{Na}^+$ , or in some cases  $[\text{M}(\text{H}_2\text{O})_2]^{++}$  by  $[\text{H}_2(\text{H}_2\text{O})_2]^{++}$ . The prep. of the following double salts is described:

All these crystallise with difficulty from the mother-liquors owing to the low concn. of some constituent ions existing in solution. They are very sparingly sol. in  $\text{H}_2\text{O}$ . Probable structures are given, in which the metal is assumed to be entirely in the cationic condition, and 2- or 4-co-ordinate. One true complex salt  $\text{Na}_6[\text{Cu}(\text{P}_2\text{O}_7)_2] \cdot 16\text{H}_2\text{O}$  was obtained.  $\text{Na}_4\text{P}_2\text{O}_7 \cdot 10\text{H}_2\text{O}$  is probably  $[\text{Na}(\text{H}_2\text{O})_4]_2[\text{Na}_2(\text{H}_2\text{O})_2]^{++}[\text{P}_2\text{O}_7]^{--}$ .

A. J. E. W.

**Spontaneous transformation of hypophosphoric acid.** P. NYLEN (Z. anorg. Chem., 1936, 229, 36—44).—Crystals of  $\text{H}_4\text{P}_2\text{O}_6$  preserved in a sealed tube change in 1—2 months at room temp. to a viscous liquid. The anhyd. acid undergoes a similar change in 5 days. The product is a mixture of  $\text{H}_3\text{PO}_3$ ,  $\text{H}_3\text{PO}_4$ , and  $\text{H}_4\text{P}_2\text{O}_7$ . An explanation based on the constitution of the acids is offered.

F. L. U.

**Phosphorus nitrides  $\text{P}_3\text{N}_5$  and  $\text{PN}$ .** H. MOUREU and P. ROCQUET (Bull. Soc. chim., 1936, [v], 3, 1801—1811).—Continued heating of  $\text{PN}_3\text{H}$  at 450° in a vac. yields  $\text{P}_3\text{N}_5$ . When heated to 730° in a vac.  $\text{P}_3\text{N}_5$  yields  $\text{PN}$  which sublimes in a vac.  $\text{PN}$  exists in two forms. The more stable red form reduces warm conc.  $\text{H}_2\text{SO}_4$ , but this reaction is very slow in the cold. The yellow form, which can be isolated only at low temp., is readily sol. in  $\text{H}_2\text{SO}_4$  and reduces the latter even at room temp. On warming in air it ignites. Neither form shows cryst. structure when examined by X-rays.  $\text{PN}$  does not react with  $\text{N}_2$  at any temp., but a current of dry  $\text{NH}_3$  at 850° converts it back into  $\text{P}_3\text{N}_5$ .

J. W. S.

**Pyroantimonates of bivalent metals:  $\text{Ca}_2\text{Sb}_2\text{O}_7$ ,  $\text{Cd}_2\text{Sb}_2\text{O}_7$ ,  $\text{Pb}_2\text{Sb}_2\text{O}_7$ .** M. BACCAREDDA (Gazzetta, 1936, 66, 539—543; cf. A., 1933, 692).—Pure  $\text{Ca}_2\text{Sb}_2\text{O}_7$  and  $\text{Cd}_2\text{Sb}_2\text{O}_7$  are prepared by heating to redness  $\text{Sb}_2\text{O}_5$  mixed with excess of  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  or  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , respectively, and washing the products with  $\text{H}_2\text{O}$  and dil.  $\text{AcOH}$ .  $\text{Pb}_2\text{Sb}_2\text{O}_7$  is obtained by heating a mixture of  $\text{Sb}_2\text{O}_5$  and  $\text{Pb}(\text{OAc})_2 \cdot 3\text{H}_2\text{O}$  in the theoretical amounts. The three substances are cubic, space-group  $O_h$ , 8 mols. per unit cell, and  $a$  10.30, 10.16, 10.68 Å.,  $d_{\text{calc}}$  5.32, 7.34, 8.40,  $d_{\text{obs}}$  4.30, 5.62, 6.72, for the Ca, Cd, and Pb compounds, respectively.

O. J. W.

**Formation of dithionate by the action of pyrosulphate on sulphite.** P. BAUMGARTEN (J.C.S., 1936, 1569—1570; cf. A., 1932, 1219).—Contrary to the observation of Bassett and Henry (A., 1935, 1090),  $\text{K}_2\text{SO}_3$  prepared from  $\text{KOH}$  and  $\text{SO}_2$  reacts with  $\text{K}_2\text{S}_2\text{O}_7$  in aq. solution in presence of  $\text{KHCO}_3$  with formation of  $\text{K}_2\text{S}_2\text{O}_6$ .

A. J. E. W.

**Higher polythionates. II.** A. KURTENACKER and K. MATEJKA (Z. anorg. Chem., 1936, 229, 19—29; cf. A., 1928, 1201).—By increasing the  $[\text{HCl}]$  used in Raschig's method for preparing  $\text{K}_2\text{S}_5\text{O}_8$ ,  $\text{K}_2\text{S}_6\text{O}_8$  can be prepared and separated from the former by crystallisation. Working details are given. Still further increase in the  $[\text{HCl}]$  results in the production of higher polythionates which, however, cannot be crystallised or otherwise obtained as individuals.  $\text{K}_2\text{S}_6\text{O}_8$  is obtained as a white cryst. powder, stable

when dry. Neutral aq. solutions slowly deposit S and form  $K_2S_5O_6$ , whilst alkalis provoke immediate decomp. X-Ray powder diagrams of  $K_2S_nO_6$  ( $n=3, 4, 5, 6, >6$ ) are given. The absence from the last-named of lines proper to any of the others indicates the existence of one or more definite higher polythionates.  
F. L. U.

**Molybdenum and nitrogen.** A. SIEVERTS and G. ZAPF (Z. anorg. Chem., 1936, 229, 161—174; cf. B., 1934, 676).—Mo foil and Mo wire which have been heated at  $1400^\circ$  in a mixture of  $H_2$  and  $N_2$  absorb only very small quantities of  $N_2$  at  $900$ — $1200^\circ$ . The foil becomes brittle and recrystallises, whilst the wire is unaffected. Absorption of  $N_2$  by wire which has not been preheated is much greater, and on cooling in  $N_2$  a nitride phase, characterised both microscopically and by X-rays, separates. The initially flexible wire becomes brittle and shows a smooth instead of a fibrous fracture. A nitride with 23.5 at.-% of N still absorbs  $N_2$  freely at  $820^\circ$ .  
F. L. U.

**Amphoteric hydrated oxides, solutions of their hydrolysing salts, and their compounds of high mol. wt. XXX. Phosphotungstates and their inter-relations.** G. JANDER and H. BANTHIEN (Z. anorg. Chem., 1936, 229, 129—145; cf. this vol., 29).—The conditions under which various phosphotungstates separate from aq. solutions of their components are described.  $6Na_2O, 1.5P_2O_5, 12WO_3, 17H_2O$  is new. All compounds of this type are derived from the units  $H_3PO_4$ ,  $H_6W_6O_{21}$ , and  $P_2O_5, 12WO_3, xH_2O$ .  
F. L. U.

**Fluorine and its compounds.** O. RUFF (Ber., 1936, 59, [A], 181—194).—A lecture.

**Oxidation of inorganic reagents by ozone. II. Potassium iodide. Influence of the characteristics of the solution.** (MME.) G. GUÉRON, M. PRETTE, and J. GUÉRON (Bull. Soc. chim., 1936, [v], 3, 1841—1847; cf. this vol., 440, 441).—The action of  $O_3$  on solutions of KI in MeOH, EtOH, Bu<sup>n</sup>OH, COMe<sub>2</sub>, or cyclohexanol produces  $KIO_3$  to a greater extent than in aq. solution. Dry KI is only slightly attacked by  $O_3$  dried with  $H_2SO_4$ . After dissolution of the product, 92% of the oxidising power is found to be due to  $KIO_3$ . Addition of KCl or  $K_2SO_4$  to aq. KI has no effect on the oxidation by  $O_3$ , which yields both I and  $KIO_3$ . Buffering with conc.  $KH_2PO_4 + K_2HPO_4$ , however, decreases the amount of  $IO_3^-$  produced. The formation of  $KIO_3$  appears to occur only in regions of local alkalinity. Attempts to demonstrate this were unsuccessful, owing to irregularities, apparently of an electro-kinetic nature. The limitations of the KI method of determining  $O_3$  are discussed.  
J. W. S.

**Oxalato complex compounds of tervalent manganese.** G. H. CARTLEDGE and W. P. ERICKS (J. Amer. Chem. Soc., 1936, 58, 2061—2065).—The prep. and properties of  $K_3[Mn(C_2O_4)_3] \cdot 3H_2O$ ,  $K[Mn(C_2O_4)_2(H_2O)_2] \cdot 3H_2O$ ,  $K[Mn(C_2O_4)(H_2O)_2] \cdot 2H_2O$ , and  $[Co(NH_3)_6][Mn(C_2O_4)_3] \cdot xH_2O$ , and  $K[Mn(C_3H_3O_4)_2(H_2O)_2] \cdot 2H_2O$  are described.  
E. S. H.

**Ferrites.** R. S. HILPERT (Rec. trav. chim., 1936, 55, 963—966).—A reply to van Arkel *et al.* (this vol., 810).  
R. S.

**Compact disperse ferric hydroxide.** H. W. KOHLSCHÜTTER and H. NITSCHMANN (Z. anorg. Chem., 1936, 229, 45—48; cf. this vol., 167).—Comments on a paper by Krause and Krzyzanski (*ibid.*, 947).  
F. L. U.

**Calcium ferrite hydrates.** H. HOFFMANN (Zement, 1936, 25, 675—680, 693—698, 711—716, and Mitt. zementtech. Inst. Tech. Hochschule Berlin, 1935, 52, 63 pp.).—Interaction of a mixture of  $FeCl_3$  and  $CaCl_2$  in  $H_2O$  with a large excess of  $CO_2$ -free NaOH solution afforded material containing  $CaO : Fe_2O_3 : H_2O = 4 : 1 : 14$  and  $4 : 1 : 7$ . A mixture of EtOH and glycerol extracted no CaO, and the X-ray powder patterns were distinct from one another and from those of  $Fe_2O_3 \cdot H_2O$  ( $\alpha$ - and  $\beta$ -forms),  $Ca(OH)_2$ , and  $CaCO_3$ . Anhyd.  $2CaO, Fe_2O_3$  shaken with  $H_2O$  or aq.  $Ca(OH)_2$  gave a solution containing about 1060 mg. of CaO per litre and no  $Fe_2O_3$ . In two experiments analysis of the solid phase gave  $CaO : Fe_2O_3 = 3.4$  and  $2.9$ , respectively, and an X-ray powder pattern similar to the  $4 : 1 : 7$  prep.  $CaO, Fe_2O_3$  does not react with  $H_2O$  or aq.  $Ca(OH)_2$  whilst  $4CaO, Fe_2O_3, Al_2O_3$  gives an equilibrium solution containing 640 mg. of CaO per litre, and a solid phase containing  $Fe(OH)_3$ ,  $3CaO, Al_2O_3$  hydrate, and an unknown hydrated Ca ferrite which probably also exists in equilibrium with solutions containing between 1060 and 640 mg. of CaO per litre.  
G. H. C.

**Ferric ammonium chlorides. Anomalous mixed crystals.** E. GRUNER and L. SIEG (Z. anorg. Chem., 1936, 229, 175—187).— $NH_4Cl$  forms anomalous mixed crystals only with those chlorides of heavy metals which show a moderate tendency to double salt formation, and then only when such double salts are readily sol. The phenomenon is observed with  $MnCl_2$ ,  $CoCl_2$ ,  $NiCl_2$ ,  $FeCl_2$ , and especially  $FeCl_3$ . Crystals in which the  $FeCl_3$  content is  $> 14\%$  show only  $NH_4Cl$  in the X-ray diagram, with the lattice const. very little changed. When the proportion of  $FeCl_3$  is  $> 45\%$  the lattice of the double salt  $(NH_4)_2[FeCl_5 \cdot H_2O]$  (characterised by its  $H_2O$ -v.p.) is observed. The structure of the mixed crystals is discussed.  
F. L. U.

**Constitution of compounds formed in A. Martini's micro-reactions.** J. V. DUBSKY and A. LANGER (Chem. Listy, 1936, 30, 227—230).—The compounds described by Martini (A., 1929, 287) are of the type  $M(CNS)_2 \cdot B_2$  ( $M = Co, Ni, \text{ or } Cd$ ;  $B = C_5H_5N$  or  $NH_2Ph$ ); the formulæ proposed by Martini are erroneous.  
R. T.

**Quantitative spectral analysis.** H. TRICHE (Bull. Soc., chim., 1936, [v], 3, 1817—1820).—The methods of controlled comparison spectra and of internal scale are equally accurate and both yield trustworthy results.  
J. W. S.

**Crystallographic identification of substances.** V. V. DOLIVO-DOBROVOLSKI (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 33—48).—A discussion.  
R. T.

**Accuracy of acid-base titrations calculated from the titration curves.** S. KILPI (Suomen Kem., 1936, 9, A, 93—94; B, 19—20; cf. A., 1935, 594, 1091, 1214; this vol., 692).—Expressions based

on Van Slyke's equation for the buffer capacity (cf. A., 1922, i, 893) are derived for the inaccuracy in a weak acid or base-strong base or acid titration due to an error in the end-point  $p_H$ .  
R. C. M.

**Roqui-purple, a new indicator.** F. L. RODUTA and G. A. QUBILAN (Searchlight, 1936, 1, No. 1, Reprint).—Roqui-purple, prepared from dinitrophenylhydrazine and naphthaquinonesulphonate in MeOH, is claimed to be a good indicator, comparing very favourably with phenolphthalein.  
F. R. S.

**Interferometric analysis of heavy water.** N. S. FILIPPOVA and M. M. SLUCKAJA (Acta Physicochim. U.R.S.S., 1936, 5, 131—136).—A modification of the method hitherto used (A., 1934, 618) for the interferometric analysis of  $H_2O$ - $D_2O$  mixtures is described. The temp. coeff. of  $\Delta n$  has been determined at 18—25° for a series of mixtures.  
F. L. U.

**Titration errors due to formation of mixed crystals in potentiometric analysis.** H. FLOOD (Z. anorg. Chem., 1936, 229, 76—84).—Expressions for the displacement of the end-point obtained from the potentiometric titration curves in pptn. reactions are deduced for the cases where (1) complete equilibrium between ppt. and solution is rapidly established, (2) equilibrium is not established after each addition of titration liquid.  
F. L. U.

**Titration errors in the potentiometric determination of bromide and chloride in mixtures.** H. FLOOD and B. BRUUN (Z. anorg. Chem., 1936, 229, 85—96; cf. preceding abstract).—The % displacement of the end-point in potentiometric titrations of  $Br^-Cl^-$  mixtures by  $AgNO_3$  after addition of  $Ba(NO_3)_2$  is given by  $100(b/a)\{1 - (b/La)^{1/L} - (1/L)\}$ , in which  $b/a = Cl^-/Br^-$ ,  $L = 400$  = ratio of solubility product of  $AgCl$  to that of  $AgBr$ . The function of  $Ba(NO_3)_2$  is to coagulate colloidal  $Ag$  halide. Errors in the absence of coagulating electrolyte are not entirely explicable by mixed crystal formation, but are due partly to adsorption.  
F. L. U.

**Colorimetric determination of small quantities of bromine in presence of a large excess of chlorine.** P. BALATRE (J. Pharm. Chim., 1936, [viii], 24, 409—413).—Small amounts of  $Br^-$  are best determined (error <5%) by a modification of the method of Stenger *et al.* (A., 1935, 835) in which  $Br^-$  is liberated by  $0.005N-NH_2Cl$ , suitably buffered, followed by  $Na_2S_2O_3$ . The technique is described.  
J. W. B.

**Determination of dissolved oxygen in boiler feed-water.**—See B., 1936, 1023.

**Determination of small concentrations of sulphur dioxide and hydrogen sulphide in air.** II. V. G. GUREVITSCH and V. P. VENDT (J. Gen. Chem. Russ., 1936, 6, 962—971; cf. A., 1930, 879).— $SO_2$  and  $H_2S$  are converted into  $H_2SO_4$ , which is determined.  $SO_2$  is oxidised by air in 0.2% aq.  $NH_3$  during 30 min.; only 3% of  $H_2S$  present in  $SO_2$  is oxidised under the same conditions. The  $(NH_4)_2S$  thus formed gives  $(NH_4)_2SO_4$  when treated with  $H_2O_2$ . The determination of  $SO_4^{2-}$  before and after the treatment with  $H_2O_2$  affords the vals. of  $SO_2$  and  $H_2S$ . Klinker's method of determining  $H_2SO_4$  (A., 1925, ii, 239)

is not sensitive enough. The nephelometric method of determining  $PbSO_4$  in dil. EtOH is convenient; the error is  $\pm 2.5 \times 10^{-7}$  g. of  $SO_2$  or  $H_2S$ .  
J. J. B.

**Determination of sulphur in plain and alloy steels.**—See B., 1936, 1098.

**Direct titration of sulphate with barium chloride using sodium rhodizonate as external indicator.** A. MUTSCHIN and R. POLLAK (Z. anal. Chem., 1936, 106, 385—399).—The use of Na rhodizonate (I) as external indicator, and titration in cold neutral solution, is recommended in order to avoid the decomp. of (I) by acids. In presence of much  $NH_4Cl$ , 10—20% of  $COMe_2$  is added to overcome the resulting interference with the pptn. of  $BaSO_4$ . In presence of Na and small amounts of K,  $COMe_2 + AcOH$  is added. Mg interferes slightly owing to the pink coloration developed with (I). Titration is not possible in presence of Ca or heavy metals.  
J. S. A.

**Determination of small quantities of nitric acid by means of phenoldisulphonic acid.** E. REMY and H. ENZENAUER (Arch. Pharm., 1936, 274, 435—439).—The  $NO_3^-$  content of  $H_2O$  in presence of  $NO_2^-$  is determined colorimetrically using a solution of the product of PhOH and fuming  $H_2SO_4$ , neutralised with 50% KOH. Alkaline K Na tartrate solution is used to prevent pptn. of  $Ca^{++}$  and  $Mg^{++}$ .  
F. R. G.

**Detection of nitrites.** J. C. GIBLIN and G. CHAPMAN (Analyst, 1936, 61, 686).—The test, sensitive to 1 p.p.m., is based on the formation of Me-orange from  $NPhEt_2$  and sulphanilic acid.  
E. C. S.

**Colorimetric determination of phosphorus.** H. L. BROSE and E. B. JONES (Nature, 1936, 138, 644).—The method described enables a reaction to be followed by means of a photo-electric colorimeter until equilibrium is reached. In a modification of the Fiske-Sulbarow microchemical method,  $10^{-9}$  g. of P per c.c. can be detected and changes of  $<10^{-7}$  g. can be accurately measured. With very small amounts of P the approx. steady state is reached in 20 min., but with  $\sim 0.5 \times 10^{-6}$  g. per c.c. the colour should not be read for 2 hr.  
L. S. T.

**Oceanographical chemical investigations with the Zeiss Pulfrich photometer.** I. Apparatus. II. Procedure. III. Determination of phosphate. IV. Influence of other substances on the phosphate determination. V. Determination of total phosphate, plankton phosphate (living matter) and of turbidity. H. KALLE (Ann. Hydrogr. marit. Meteorol., 1931, 59, 313—317; 1933, 61, 124—128; 1934, 62, 65—74, 95—102; 1935, 63, 58—65, 195—204; Chem. Zentr., 1936, i, 830—831).—III. The optimum conditions for the use of Osloer's molybdate reagent were determined.

IV. Traces of Cu reduce the colour intensity in the determination of  $PO_4^{3-}$  in sea- $H_2O$ .  $SiO_2$  has no effect.  $AsO_4^{3-}$  and oxalic acid interfere.  $As_2O_3$  intensifies the colour.

V. 25 c.c. of the sea-water are evaporated with 1 c.c. of conc.  $H_2SO_4$  and 0.2 c.c. of 0.001M aq.  $CuSO_4$ . The residue is dissolved in 5 c.c. of  $H_2O$ , and 1 c.c. of 4%  $CS(NH_2)_2$  solution is added to reduce  $As^V$

to  $\text{As}^{\text{III}}$ . 5 drops of 0.05% aq. 2:5 dinitrophenol are added and the solution is neutralised with aq.  $\text{NH}_3$ . Total  $\text{PO}_4^{\text{'''}}$  is then determined. The plankton  $\text{PO}_4^{\text{'''}}$  is determined by difference after filtering through a fine paper to remove plankton. The determination of turbidity with the Pulfrich photometer is described.

H. J. E.

**Determination of phosphoric acid.**—See B., 1936, 1036, 1059.

**Boric acids and borates.** Borax as titration substance. G. KILDE (Dansk Tidsskr. Farm., 1936, 10, 273—296).—Analytical borax should be recryst. below  $50^\circ$  and kept over saturated aq.  $\text{NaCl}$ +sucrose to avoid formation of the pentahydrate. M. H. M. A.

**Micrometric estimation of quartz in rocks.**—See B., 1936, 1093.

**Detection of carbon monoxide.** A. LABÒ (Boll. chim.-farm., 1936, 75, 521—531).—Methods for the detection and determination of CO are discussed.

O. J. W.

**Determination of krypton content of air.** F. KOROSY (Magyar chem. Fol., 1935, 41, 21—25; Chem. Zentr., 1936, i, 385).—The Kr: A ratio is determined spectrographically in an unfractionated inert gas mixture.

J. S. A.

**Causes of contamination of precipitates. III. Precipitation processes in which various electrolytes take part. Classification.** Z. KARAOGLANOV (Z. anal. Chem., 1936, 106, 399—407).—From the author's previous work, pptn. processes are classified into four types. (a) Pptns. unaccompanied by any secondary reactions, e.g., pptn. of  $\text{AgCl}$  or  $\text{CaC}_2\text{O}_4$ . The formation of pure pptns. in these cases is contrary to adsorption theories of contamination. (b) Pptns. accompanied by a simultaneous secondary reaction, e.g., pptn. of  $\text{SO}_4^{\text{''}}$  or  $\text{CrO}_4^{\text{''}}$  with  $\text{BaCl}_2$ ,  $\text{Ba}(\text{NO}_3)_2$ ,  $\text{PbCl}_2$ , or  $\text{PbBr}_2$  (cf. this vol., 1352). (c) Pptns. followed by a secondary reaction; e.g., pptn. of  $\text{Cu}(\text{OH})_2$  in presence of excess of  $\text{CuSO}_4$ , followed by formation of basic salt. (d) Pptns. accompanied by a secondary physical process, such as adsorption or mixed crystal formation.

**Qualitative analysis of cations without use of  $\text{H}_2\text{S}$  or  $(\text{NH}_4)_2\text{S}$ .** M. B. SCHTSCHIGOL and N. M. DOUBENSKI (Ann. Chim. Analyt., 1936, [in], 18, 257—261).—Ag, Hg, and Pb are pptd. with  $\text{HCl}$ , and the solution is evaporated down with  $\text{HNO}_3$ , removing Sn and Sb as oxides. The solution is treated with  $\text{Na}_2\text{CO}_3$ + $\text{NH}_4\text{Cl}$ +aq.  $\text{NH}_3$ , thereby pptg. Bi, Fe, Mn, Al, Cr, Ca, Sr, Ba, and Mg (in presence of  $\text{PO}_4^{\text{'''}}$ ). Al and Cr are dissolved by treating the ppt. with  $\text{Na}_2\text{O}_2$ , and Ba, Ca, Sr, and Mg are dissolved away from Bi, Fe, and Mn by warming with  $\text{Na}_2\text{HPO}_4$ + $\text{AcOH}$ .

J. S. A.

**Potentiometric determination of calcium in solutions.** D. M. GREENBERG and C. E. LARSON (J. Biol. Chem., 1936, 115, 769—770).—Ultrafiltration experiments show that gelatin adsorbs little or no Ca at its isoelectric point ( $p_{\text{H}}$  4.8) or at  $p_{\text{H}}$  4.3, in disagreement with Tendeloo's results (this vol., 443) obtained by an e.m.f. method.

F. A. A.

**Detection of zinc with potassium ferricyanide and *p*-phenetidine.** L. SZEDELLEDY and S. TANAY (Z. anal. Chem., 1936, 106, 342—348).—0.00005 mg. of Zn may be detected by the blue coloration given by  $p\text{-OMe}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ + $\text{K}_3\text{Fe}(\text{CN})_6$  in presence of Zn. In presence of Ag, Pb, Bi, and Sn the sensitivity is lowered by the simultaneous formation of white ferrocyanide ppts. A large excess of Mg, K, Na, Ca, Sr, or Ba has no influence.

J. S. A.

**Internal electrolysis. I. Determination of small quantities of cadmium and nickel in zinc.** J. G. FIFE (Analyst., 1936, 61, 681—684; cf. A., 1930, 884).—To determine Cd an anolyte containing  $\text{ZnCl}_2$  and  $\text{NH}_4\text{Cl}$  and a catholyte containing the mixture to be analysed,  $\text{NH}_4\text{Cl}$ ,  $\text{NaOAc}$ ,  $\text{AcOH}$ , and  $\text{N}_2\text{H}_4\cdot\text{HCl}$  are recommended. Electrolysis for 30 min. is required for  $>10$  mg. of Cd, and 45 min. for  $>10$  mg., at  $70^\circ$ . For the determination of Ni, the anolyte contains, in addition, aq.  $\text{NH}_3$ , and the catholyte contains the mixture to be analysed,  $\text{NH}_4\text{Cl}$ , and  $\text{Na}_2\text{SO}_3$ . The electrolysis is carried out for 30—60 min. at  $65^\circ$ .

E. C. S.

**[Spectrographic] determination of cadmium and lead in zinc.**—See B., 1936, 1099.

**Determination of lead in potable waters.**—See B., 1936, 1134.

**Electrolytic determination of copper.** H. MOHLER and J. HARTNAGEL (Mitt. Lebensm. Hyg., 1936, 27, 131—133).—The apparatus described provides for voltage and current control over a wide range and enables 5—10 mg. of Cu to be deposited at  $60$ — $70^\circ$  in 40 min. on a Pt gauze cathode, using a Pt spiral anode. Canned vegetables are ashed and extracted in presence of  $\text{H}_2\text{SO}_4$ , removal of  $\text{SiO}_2$  being unnecessary; 66—102 mg. of Cu per kg. were found.

J. G.

**Determination of cuprous oxide as applied to sugar analysis.**—See B., 1936, 1063.

**Sensitive test for copper.**—See this vol., 1398.

**8-Hydroxyquinoline method for determination of aluminium, iron, and titanium.** L. STUCKERT and F. W. MEIER (Sprechsaal Keram., 1935, 68, 527—529; Chem. Zentr., 1936, i, 386).—The gravimetric method is trustworthy if  $\text{SiO}_2$  is first removed. Titration with  $\text{KBrO}_3$ + $\text{KBr}$  gives low results in presence of Fe.

J. S. A.

**Analysis of felspar. Volumetric determination of alumina.**—See B., 1936, 1036.

**Catalytic detection of manganese.** L. SZEDELLEDY and M. BARTFAY (Z. anal. Chem., 1936, 106, 408—416).— $10^{-9}$  g. of Mn in 5 c.c. of solution may be detected by the catalysed oxidation of *p*-phenetidine (I) [0.1 c.c. of 0.1% (I) hydrochloride] by  $\text{KIO}_4$  (0.5 c.c. of saturated solution) in neutral solution. 1000 parts of Cr, Fe (in presence of  $\text{NaF}$ ), Co, or Sn do not interfere; in presence of Zn, Sn, Hg, and Al,  $\text{NaOAc}$  is added.

J. S. A.

**Determination of manganese in tungsten and ferrotungsten.**—See B., 1936, 1099.

**Macro-detection of cobalt. II.** F. P. DWYER (J. Proc. Austral. Chem. Inst., 1936, 3, 277—280).—

Methylene-blue (I) + KCN, or (I) + dimethylglyoxime (II) +  $\text{NH}_3$  are added to the solution. The strong reducing action of  $\text{K}_4\text{Co}(\text{CN})_6$  or the Co-(II) complex reduces (I) in presence of  $5\text{--}10 \times 10^{-6}$  g. of Co. Fe, Ni, Cr, Cu, Sn, and Ti, which interfere, are removed by successive treatment with  $\text{KMnO}_4$ , aq.  $\text{SO}_2$ , and KCNS before adding an excess of the reagent. J. S. A.

Gravimetric separation of quadri- and hexavalent uranium. I. F. HECHT and H. KRAFFT-EBING (Z. anal. Chem., 1936, 106, 321—330).— $\text{U}^{\text{IV}}$  may be quantitatively separated from  $\text{U}^{\text{VI}}$  by pptn. with  $\text{H}_4\text{P}_2\text{O}_6$  in acid solution. Subsequent oxidation of the ppt. and determination of U as  $(\text{UO}_2)_2\text{P}_2\text{O}_7$  gives high results. Mo and  $\text{U}^{\text{VI}}$  may be separated by pptg. U from 0.5%  $\text{H}_2\text{SO}_4$  solution by means of 8-hydroxyquinoline (I). U may then be pptd. by (I) on addition of  $\text{NH}_4\text{OAc}$ . The method is proposed, following the removal of P with  $(\text{NH}_4)_2\text{MoO}_4$ , for the determination of U after pptn. with  $\text{H}_4\text{P}_2\text{O}_6$ . J. S. A.

Systematic analytical procedure without use of hydrogen sulphide. V. J. PETRASCHENJ (Z. anal. Chem., 1936, 106, 330—342).—The method is based on the solubilities of the phosphates. Sn and Sb are first removed by evaporation with  $\text{HNO}_3$ ; Pb and Ag are pptd. as chlorides. The solution is then treated with  $(\text{NH}_4)_2\text{HPO}_4$  and a large excess of  $\text{NH}_3$ . The ppt. is further subdivided into groups based on the differing solubility of the phosphates in 2N-AcOH and in 0.5N- $\text{HNO}_3$ . J. S. A.

Analysis of gold-palladium-silver alloys.—See B., 1936, 1099.

Determination of gold in dental gold alloys.—See B., 1936, 1099.

Gas-tight furnace for thermocouple standardisation. C. D. NIVEN (Canad. J. Res., 1936, 14, A, 177—180).—A gas-tight furnace with  $\text{H}_2\text{O}$ -cooled lid for calibrating thermocouples in molten metals in an atm. of  $\text{N}_2$  or coal gas is described. R. S. B.

Preparation of a sensitive vacuum thermoelement. E. PICKER and G. RUDINGER (Z. tech. Physik, 1935, 16, 265—267; Chem. Zentr., 1936, i, 814).—The element consists of two thin overlapping layers of Fe and constantan, prepared by evaporation in vac. onto a thin strip of mica, which is finally mounted in vac. H. J. E.

Simple apparatus for measuring light absorption. J. AUSCHKAP (Latvij. Univ. Raksti, 1936, 3, 11—14).—An absorption cell for the comparison of two liquids is described. H. J. E.

Complementary filters for photographing the Raman spectra of crystal powders. R. ANANTHAKRISHNAN (Current Sci., 1936, 5, 131—132).—Monochromatic light is used for excitation, and all scattered light of this  $\lambda$  is absorbed before entering the spectrograph. C. W. G.

Filter opaque to ultra-violet light. G. HEYNE and M. SCHÖN (Angew. Chem., 1936, 49, 784).—Durophen lacquer 218V in thin layers is opaque to light of  $\lambda < 4000$  Å., but practically non-absorbing in the visible region. J. S. A.

Quantitative analysis of the photochemical bleaching of visual purple solutions in monochromatic light. H. J. A. DARTNALL, C. P. GOOD-EVE, and R. J. LYTCHGOE (Proc. Roy. Soc., 1936, A, 150, 158—170).—An apparatus has been devised for determining the rate of bleaching and an equation is derived for the change of absorption with time, under ideal photochemical conditions. L. L. B.

Photo-electric sedimentation measurement. C. ENDERS and A. SPIEGL (Kolloid-Z., 1936, 77, 37—38).—The measurement of sedimentation by determination of the change in absorption of light compares favourably with the kinetic method. E. S. H.

Standardisation of photo-electric cells for the measurement of energy. H. H. POOLE and W. R. G. ATKINS (Sci. Proc. Roy. Dublin Soc., 1936, 21, 363—379).—Using a W-filament lamp having a rated colour temp. of 2360° abs. the consts. for a Weston Se rectifier cell have been determined for different regions of the spectrum isolated by means of Jena, and Corning sextant green, glass filters. Owing to uncertainties in the colour temp. of the source, these consts. may contain an error up to 20%; further, the spectral distribution of energy for the standard lamp is very different from that for daylight, which may account for differences between the results of daylight measurements (using the consts.) and those of Abbot (A., 1931, 592). R. C. M.

Large quartz spectrograph for examination of biological material. J. S. FOSTER (Canad. J. Res., 1936, 14, A, 173—176).—A comparatively inexpensive apparatus with a Cornu prism is described. R. S. B.

Spectro-pleochroism-meter and investigation of mineral dichroism. N. VEDENEVA and S. GRUM-GRSHIMAILO (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 383—385; cf. A., 1935, 58).—Apparatus for the measurement of the spectral distribution of dichroism at varying temp. is described. With increasing temp. the max. dichroism of coloured tourmaline is decreased and shifted to longer  $\lambda$ . For pink and blue tourmalines the change is irreversible above 425° and 275°, respectively. O. D. S.

Measurements of the intensity of X-ray radiation with a proportional amplifier. V. VEKSLER and B. ISAEV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 369—370).—The amplifier was tested by means of the continuous spectrum of W. O. D. S.

X-Ray fluorescent screens. H. STEPS (Fortschr. Röntgenstr., 1935, 52, 293—299; Chem. Zentr., 1936, i, 826).—A photometric method of measuring the intensity of fluorescence is described. H. J. E.

Thermal control in minimum-deviation refractometry and temperature coefficients for a medium flint glass. L. W. TILTON (J. Res. Nat. Bur. Stand., 1936, 17, 389—400).—Details are given of an arrangement in which the spectroscopic prism is mounted and adjusted in a thermostated bath of stirred air contained in a water-jacketed cylinder provided with plane-parallel windows capable of adjustment to cover a wide range of prism angles.

and refractive media. Data showing the variation of  $n$  with temp. for a medium flint glass are recorded.

J. W. S.

**Step compensator for the Jamin interference refractometer when illuminated with white light.** H. BILLING (Z. Physik, 1936, 103, 57—60).—For direct readings the eyepiece scale has a limited measurement range. A five-fold extension is obtained by inserting a glass plate cut into four steps, each 10  $\mu$  thick, in the beam passing through the comparison tube. The field of view is thereby divided into five strips in one of which the interference fringe appears.

H. C. G.

**High-temperature vacuum Debye-Scherrer X-ray camera.** J. E. DORN and G. GLOCKLER (Rev. Sci. Instr., 1936, [ii], 7, 389—390).—Temp. up to 500° can be used, and are measured by means of a thermocouple.

C. W. G.

**Use of high-frequency discharge tubes as electrical counters.** S. C. CURRAN (Phil. Mag., 1936, [vii], 22, 599—616).—An investigation of the working conditions and sensitivity of various kinds of tubes is reported.

N. M. B.

**Amplifier for the coincidences of proportional wire counters.** G. BERNADINI, D. BOCCIARELLI, and F. OPPENHEIMER (Rev. Sci. Instr., 1936, [ii], 7, 382—383).—The coincidences between two proportional wire counters are used to detect the recoil protons ejected by neutrons from a thin layer of paraffin.

C. W. G.

**Stereo-comparator for work with Wilson's chamber.** L. GROSCHÉV, N. DOBROTIN, and J. FRANK (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 289—290).—An instrument for calculating the spatial distribution of tracks of particles in the Wilson chamber from stereoscopic photographs is described.

R. S. B.

**Photography of minima in the magneto-optic apparatus.** G. HUGHES (J. Amer. Chem. Soc., 1936, 58, 1924—1932).—Technique demonstrating the reality of the min. is described.

E. S. H.

**Resonance method of determining dielectric constants.** F. HUMMEL (Z. tech. Physik, 1935, 16, 264—265; Chem. Zentr., 1936, i, 116).—Apparatus is described.

J. S. A.

**Application of radio waves to measurement of dielectric constants of non-conducting liquids.** D. DOBORZYNSKI (Hochfrequenztech., 1935, 46, 92—94; Chem. Zentr., 1936, i, 116—117).—The use of radio-frequencies in measurements by the resonance method is described.

J. S. A.

**Applications of dielectric constant measurement.** J. HENRION (Rev. Univ. Mines, 1935, [viii], 11, 412—415; Chem. Zentr., 1936, i, 117).—A review.

J. S. A.

**Normal element of small potential.** W. GREMMER (Physikal. Z., 1936, 37, 697—699).—The use of Cd amalgams of different concn. in CdSO<sub>4</sub> solution as a normal element of small potential has been investigated.

A. J. M.

**Applications of the glass electrode in conjunction with the valve potentiometer.** F. MÜLLER

and W. DURICHEN (Z. Elektrochem., 1936, 42, 730—732).—Apparatus and technique for automatic  $p_H$  control are described.

E. S. H.

**Agar and potassium chloride bridge for use with calomel half-cells.** I. M. ROBERTSON (Analyst, 1936, 61, 687—688).

E. C. S.

**Electrometric  $p_H$  equipment and hysteresis of calomel electrodes.** B. WINGFIELD and S. F. ACREE (J. Amer. Leather Chem. Assoc., 1936, 31, 403—406).—The temp. error of a saturated calomel electrode is 0.04  $p_H$  for a change of 8.4°. Measurements should be conducted in a const.-temp. bath or under conditions which have varied  $\pm 1^\circ$  for 7—10 hr. A glass electrode assembly in which the calomel electrode is enclosed in a protecting Dewar flask is described.

D. W.

**Electrolysis stand.** W. BORKENSTEIN (Z. anal. Chem., 1936, 106, 427—429).

J. S. A.

**Phosphorus pipette for determination of oxygen.** Z. B. SÓLYOM (Magyar chem. Fol., 1935, 41, 94—95; Chem. Zentr., 1936, i, 385).

J. S. A.

**Automatic pipette for sedimentation analysis.** E. HOFFMANN (Kolloid-Z., 1936, 77, 44—45).

E. S. H.

**Pore viscosimetry of molecular aggregation in solution.** H. WISLICHENUS (J. pr. Chem., 1936, [ii], 147, 124—132; cf. A., 1933, 801).—An improved form of the pore viscosimeter is described and its use is illustrated by results obtained for sucrose and sol. starch solutions.

J. W. S.

**Forceps for handling radioactive substances.** L. F. CURTISS (Rev. Sci. Instr., 1936, [ii], 7, 393—394).—Protection for the operator's hand is secured by a length of about 20 cm. The forceps are self-closing.

C. W. G.

**Pyrex glass seals.** V. H. FRAENCKEL (Rev. Sci. Instr., 1936, [ii], 7, 395).—Corning glasses suitable for sealing to Pyrex glasses are listed.

C. W. G.

**Metal oil diffusion pump: multiple nozzle type.** I. AMDUR (Rev. Sci. Instr., 1936, [ii], 7, 395—396).—A simple all-metal pump with a speed of 250 litres per sec. is described.

C. W. G.

**Arrangement for mixing liquids in bottles.** H. WOLLENBERG (Pharm. Zentr., 1936, 77, 660).—A rotary shaking device is described.

J. S. A.

**Adjustable support and stand for Bunsen burners.** I. A. BALINKIN (J. Chem. Educ., 1936, 13, 414).

L. S. T.

**Calculation of surface tension from experiment.** IV. A. W. PORTER (Phil. Mag., 1936, [vii], 22, 726—729; cf. this vol., 552).—Corrections previously considered for the rise in tubes of circular section and various widths for zero angle of contact are extended to various angles in the range 0—90°.

N. M. B.

**Thermal decomposition of systems of solid and gaseous components.** J. PIAZZA (An. Inst. Invest. cient. tec., 1934, No. 3—4, 57—60; Chem. Zentr., 1936, i, 384).—A dilatometric technique is described.

J. S. A.

**Preparation of tin and tin alloys for microscopical examination.** H. J. TAFS (J. Roy. Micro-

scop. Soc., 1936, [iii], 56, 300—306).—Modified procedure for polishing, etching, and mounting is described. E. S. H.

**Ebulliometry.** W. SWIENTOSLAWSKI (Mem. Acad. Polonaise, 1936, A, No. 3, 1—196).—A monograph giving detailed descriptions of the construction and applications of modern ebulliometers. J. W. S.

**Efficient expansible mechanical stirrer and its use in organic syntheses.** J. G. HILDEBRAND, jun., and M. T. BOGERT (Coll. Czech. Chem. Comm., 1936, 9, 391—394).—The lower ends of pieces of heavy steel spring are attached to the bottom of a vertical brass rod and the other ends are attached to a brass tube sliding over the rod. When the stirrer has been inserted into the flask the stirrer blades are bowed out by forcing down the brass tube with nuts. The device includes a Hg seal and is especially useful for stirring very viscous material. The prep. of Et cyclopentanone-2-carboxylate from Et adipate and Na in PhMe is described, and the yield was increased from 66% to 80% by using the stirrer. J. G. A. G.

**Tables for converting  $d_{20}^{20}$  into  $d_4^{20}$  (vac.).** W. FRIEDEL (Arch. Pharm., 1936, 274, 392—397).—Vals. of  $d_{20}^{20}-d_4^{20}$  (vac.) to four decimal places are given for vals. of  $d_{20}^{20}$  between 0.5892 and 1.5319.

F. R. G.

**Test for vacuum-tightness of glass grindings.** W. A. BOUGHTON (J. Chem. Educ., 1936, 13, 436).

L. S. T.

**Grinding [ends of] glass tubing and apparatus flat.** H. DRAUTZ (Chem.-Ztg., 1936, 60, 886).

J. S. A.

**Valve for fine regulation of gas pressures and its application in ion [X-ray] tubes.** V. KUNZL and J. B. SLAVÍK (Z. tech. Physik, 1935, 16, 272—276; Chem. Zentr., 1936, i, 814—815).

H. J. E.

**Measurement of small pressure differences at high absolute pressures.** E. SCHMIDT (Z. Ver. deut. Ing., 1936, 80, 635—636).—The ring balance frequently employed for this purpose, and a more sensitive apparatus of the horizontal beam balance type, are described. The latter instrument has been satisfactorily employed for determining  $\eta$  of  $H_2O$  and steam at pressures  $>250$  atm. and temp. of  $350^\circ$ .

R. B. C.

**Lecture experiments on inorganic and general chemistry.** A. KUTZELNIGG (Angew. Chem., 1936, 49, 813).—The experiments illustrate the rapid growth of fibrous  $Al_2O_3$  by treating Al with  $HgI_2$ , and the catalytic oxidation of coal gas by  $Cr_2O_3$ .

E. S. H.

**Priestley, Lavoisier, and Trudaine de Montigny.** R. E. OESPER (J. Chem. Educ., 1936, 13, 403—412).—Historical.

L. S. T.

## Geochemistry.

**Redetermination of the protium-deuterium ratio in water.** N. F. HALL and T. O. JONES (J. Amer. Chem. Soc., 1936, 58, 1915—1919).—When allowance is made for  $^{18}O$ , the H/D ratio for surface lake  $H_2O$  is  $6400 \pm 200$ .

E. S. H.

**Heavy water content of salt waters from petroleum springs.** I. T. TITANI and K. OKABE (Bull. Chem. Soc. Japan, 1936, 11, 593—597).—The  $D_2O$  content of salt waters from ten Japanese petroleum springs depends not only on the depths of the springs but also on the geological formations.

C. R. H.

**Reaction of ground-water in Finland.** A. E. SANDELIN (Suomen Kem., 1936, 9, A, 108—111).—The  $p_H$  of 95 samples of  $H_2O$  from dairies varied from 5.2 to  $>7.6$ . The acid reaction is due to  $H_2CO_3$  and other acids.

J. N. A.

**Application of  $p_H$  to mineralogy and geology.** M. DERIBERE (Ann. Chim. Analyt., 1936, [iii], 18, 262—263).—The role of  $p_H$  in determining the composition of sediments from mixed (e.g., siliceous and argillaceous) suspensions is indicated. The separability of mixed deposits by flotation depends on the  $p_H$ ; thus beryl and  $SiO_2$  have the same floatability at  $p_H$  9, and max. separability at  $p_H$  6.4.

J. S. A.

**Colloidal silica in natural waters and the "silicomolybdate" colour test.** A. R. TOURKY and D. H. BANGHAM (Nature, 1936, 138, 587—588).—The view that the colour intensity in the Dienert-Wandenbulcke reaction for  $SiO_2$  is  $\propto$  the crystalloid

$SiO_2$  is incorrect. The  $SiO_2$  which reacts with the  $NH_4$  molybdate (I) is mainly colloidal, and approx. correct results for the total  $SiO_2$  in natural  $H_2O$  are obtained when the  $SiO_2$  has been held in solution for a sufficient time. Warming to  $80^\circ$  with NaOH improves the agreement with gravimetric results. The coloured substance obtained with  $SiO_2$  and (I) is an adsorption complex, and not a true heteropolyacid.

L. S. T.

**Rapid sulphide deposition on organic residues at volcanic sulphur springs.** F. BERNAUER (Zentr. Min., 1935, A, 343—344; Chem. Zentr., 1936, i, 530).—Plant material on the shore of Porto de Levante becomes coated with Fe sulphide in a few days. The deposit gives the X-ray diagram of marcasite.

**Lake Ebeity.** S. Z. MAKAROV and I. G. DRUSHININ (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 353—374).—The  $H_2O$  contains  $HCO_3'$  0.089,  $Cl'$  11.8,  $SO_4''$  7.57,  $Br'$  0.025,  $Mg(HCO_3)_2$  0.016,  $Ca(HCO_3)_2$  0.101,  $KBr$  0.037,  $KCl$  0.026,  $MgCl_2$  2.96,  $Na_2SO_4$  12.13,  $NaCl$  15.6 g. per litre.

R. T.

**Sulphide-carbonate equilibrium in mineral waters.** P. N. PALEI (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 327—334).—A formula connecting  $[H_2S]$  with  $HS'$ ,  $S''$ ,  $CO_2$ ,  $HCO_3'$ ,  $CO_3''$ , and  $OH'$  concns. is derived.

R. T.

**Fluorides in the natural waters of Rhode Island.**—See B., 1936, 1070.

Graphic representation of the mineral and curative springs of Switzerland. A. NUSSBERGER (Mitt. Lebensm. Hyg., 1936, 27, 201—203).

E. C. S.

(A) Geology of Swiss mineral and curative springs. (B) Geological characteristics of Swiss mineral and curative springs. J. CADISCH (Mitt. Lebensm. Hyg., 1936, 27, 216—243, 244—259).—(A) The classification and mineralisation of springs and their regional grouping are discussed.

(B) The characteristics of the  $H_2O$  of individual spas are given.

E. C. S.

Surface markings on a diamond. W. H. GEORGE (Nature, 1936, 138, 616, 641).—The reproduced photomicrograph of the [111] face of a diamond shows triangular markings of the size predicted by the mosaic hypothesis of crystal structure. L. S. T.

Mechanics of metasomatism. G. W. BAIN (Econ. Geol., 1936, 31, 505—526).

L. S. T.

Granodiorite laccolith of the Malka river (Caucasus) and its content of radium. S. P. SOLOVIEV (Amer. J. Sci., 1936, [v], 32, 380—391).—This laccolith of Palaeozoic age is intruded into schists. The mean of 52 determinations of Ra is  $1.89 \times 10^{-12}$  g. per g. The upper portion of the mass contains more Ra than the lower. A granodiorite from Mt. Elbrus contains  $1.30 \times 10^{-12}$  and  $0.37 \times 10^{-12}$ . L. J. S.

Formula of aenigmatite. M. FLEISCHER (Amer. J. Sci., 1936, [v], 32, 343—348).—From published analyses the formula is deduced as  $X_4Y_{13}(Si_2O_7)_6$ , where  $X=Na, Ca, K$ , and  $Y=Fe^{II}, Fe^{III}, Ti, Mg, Mn, Al$ . A special case is  $Na_4Fe^{II}_9Fe^{III}_2Ti_2(Si_2O_7)_6$ . In rhönite part of the Si is replaced by Al, and Na by Ca (as in anorthite and albite). Chemically and crystallographically aenigmatite does not belong to the amphibole group. L. J. S.

Paragenetic relations and mode of formation of minerals and pseudomorphs of the Wendelstein Höhenzug near Nürnberg. S. KLEIN (Zentr. Min., 1935, A, 257—266; Chem. Zentr., 1936, i, 738).

H. J. E.

Occurrence of platinum in the Far East. A. A. MENIAJLOV and S. I. NABOKO (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 387—389).—The occurrence and genesis of Pt in far east Siberia are discussed. The paragenesis of sperrylite with sulphides was observed on the Khaikta river. The Amnunakt massif shows some analogy to the S. African Pt deposits, since, whilst the conen. of chromite in the dunites is low, the sulphides are mainly associated with autometamorphosed anorthosites. O. D. S.

New occurrence of montmorillonite. H. JUNG (Naturwiss., 1936, 24, 667).—Montmorillonite occurs in faults in the basalt at Dolmar near Meiningen.

A. J. M.

Hydrothermal alteration of montmorillonite to feldspar at temperatures from  $245^\circ$  to  $300^\circ$ . J. W. GRUNER (Amer. Min., 1936, 21, 511—515).—Montmorillonite (I) heated in aq.  $KHCO_3$  in Au-lined pressure bombs gives orthoclase after 7 days at  $300^\circ$ . X-Ray analysis showed the orthoclase to be adularia. At  $272^\circ$  or  $245^\circ$  longer heating is necessary. Muscovite is not formed, and 10% KCl solution had no

effect on (I) in 19 days at  $300^\circ$ . The probable reaction is  $3[(OH)_2Al_2Si_4O_{10} \cdot 2H_2O] + 4KHCO_3 \rightarrow 4KAlSi_3O_8 + 2Al(OH)_3 + 8H_2O + 4CO_2$ . L. S. T.

Salt cupolas of the Ural-Emba region, and the possibilities of their industrial exploitation. N. I. BUJALOV and M. G. VALJASCHKO (Ann. Sect. d'Anal. Physico-Chim., 1936, 9, 335—352).—Geochemical data are recorded for the NaCl-KCl-MgCl<sub>2</sub> deposits. R. T.

Halloysite and dolomite of Martonhegy (Martinsberg), Budapest. G. VAVRINECZ (Magyar chem. Fol., 1935, 41, 70—77; Chem. Zentr., 1936, i, 306).—Analyses are recorded. J. S. A.

Secondary removals and enrichments of gold in gold placers. G. BURG (Z. pr. Geol., 1935, 43, 134—139; Chem. Zentr., 1936, i, 34).—A mechanism is advanced for the process. J. S. A.

X-Ray and optical investigation of the serpentine minerals. G. C. SELFRIDGE, jun. (Amer. Min., 1936, 21, 463—503).—The 100 specimens examined can be classified in two divisions each of which shows slight modifications in the intensities of certain lines. The first division consists of varieties the patterns of which are similar in at. spacing to that of serpentine, best represented by chrysotile, and the second to that of antigorite. Chemical analyses from the lit. are discussed. Many names indicating distinct mineral species should be abandoned in favour of the terms serpentine and antigorite, respectively. L. S. T.

Minerals of Baveno granite: molybdenum glance. P. GALLITELLI (Rend. R. Ist. lombardo Sci. Lett., 1935, [ii], 68, 277—280; Chem. Zentr., 1936, i, 306).—The significance of the occurrence is discussed. J. S. A.

Molybdenum glance in the magnetic iron ore deposit of Schwarzen Krux, Schmiedefeld, Thüringer Wald. H. MORITZ (Zentr. Min., 1935, A, 340—342; Chem. Zentr., 1936, i, 529).—The ore contains 0.001—0.05% of Mo. The zones with quartz, fluorspar, and granite are richest in Mo. H. J. E.

Separation planes in magnetite. J. W. GREIG, H. E. MERWIN, and E. POSNJAK (Amer. Min., 1936, 21, 504—510).—Twinning is not the cause of the separation planes shown in the magnetites examined. L. S. T.

Devitrified felsite dykes from Ascutney Mountain, Vermont. R. BALK and P. KRIEGER (Amer. Min., 1936, 21, 516—522).—Two analyses are given. L. S. T.

Aguilarite from the Comstock Lode, Virginia City, Nevada. R. R. COATS (Amer. Min., 1936, 21, 532—534).—Ores from this lode contain aguilarite,  $Ag_2(S, Se)$ . L. S. T.

Comparative X-ray and morphological investigation of andalusite,  $(AlO)_3AlSiO_4$ , libethenite,  $(CuOH)CuPO_4$ , and adamine  $(ZnOH)ZnAsO_4$ . H. STRUNZ (Z. Krist., 1936, 94, 60—73).—Lattice constns. and probable space-groups for adamine and libethenite are determined; these substances are compared with andalusite, with which they are closely

related. The concepts of isomorphy and isotypy are discussed in regard to them. B. W. R.

**Crystal form and molecular unit of nagyagite.** B. GOSSNER (Zentr. Min., 1935, A, 321—327; Chem. Zentr., 1936, i, 528).—The crystals are tetragonal;  $a$  12.5,  $c$  30.25 Å.; 8 mols. of  $6\text{Pb}(\text{S},\text{Te})_2\text{AuTe}_2$  in unit cell. H. J. E.

**Origin of pyritic copper deposits of the mesothermal type.** J. E. A. KANIA (Econ. Geol., 1936, 31, 453—471).—Fused, powdered  $\text{Na}_2\text{S}$  has been fused separately with pyrite, chalcopyrite, sphalerite, galena, and  $\text{SiO}_2$  and the cooled melts extracted with  $\text{H}_2\text{O}$ . The behaviour of the resulting solutions and sols at temp. up to  $90^\circ$  in contact with marble, lime mud-rock, syenite porphyry, argillaceous quartzite, and carbonaceous shale and in presence or absence of  $\text{CO}_2$  and/or  $\text{H}_2\text{S}$  is recorded. Marcasite forms from  $\text{FeS}_2$  sols with little  $\text{Na}_2\text{S}$  present, and pyrite from  $\text{Na}_2\text{S}$ – $\text{FeS}_2$  solutions. Chalcopyrite crystals resulted from hot alkaline  $\text{Na}_2\text{S}$ – $\text{FeS}_2$ – $\text{CuFeS}_2$  sols as replacement in cryst. limestone. Certain mesothermal, pyritic Cu deposits are described and discussed in the light of the experimental results. L. S. T.

**Greensands of Wisconsin.** W. H. TWENHOFEL (Econ. Geol., 1936, 31, 472—487).—Analyses of glauconite from Wisconsin are recorded. L. S. T.

**Ore deposition south of Ouray, Colorado.** I, II. R. S. MOEHLMAN (Econ. Geol., 1936, 31, 377—397, 488—504).—Rock alteration and factors controlling ore deposition are described. Replacement, which has been important in the formation of the deposits, is discussed in detail. The order of deposition of minerals in the San Juan region is discussed. L. S. T.

**Magnetic minerals and the practical applications of their magnetism.** H. BRONDER (Tids.

Kjemi, 1936, 16, 124—125).—Magnetic separations are discussed. M. H. M. A.

**Characteristic properties of palygorskites.** H. LONGCHAMON (Compt. rend., 1936, 203, 672—674).—The dehydration of palygorskites (I) in air saturated with  $\text{H}_2\text{O}$  at  $15^\circ$  has been studied at 20— $1000^\circ$ . Three regions appear in the wt.–temp. curves, at 20— $100^\circ$ , near  $200^\circ$ , and near  $400^\circ$ , separated by steps of approx. const.  $\text{H}_2\text{O}$  content. It is considered that (I) exists in two forms (a) and (b), stable up to  $350^\circ$  and at 500— $750^\circ$ , respectively. With (a) a large proportion of  $\text{H}_2\text{O}$  is zeolitic and after heating at  $350^\circ$  the  $\text{H}_2\text{O}$  lost (7%) is rapidly absorbed from moist air at room temp. (a) passes irreversibly into (b) at  $400^\circ$  and the zeolitic absorption disappears. (I) are compared with the sepiolites (A., 1935, 842).

R. S. B.

**Impregnation of North African phosphates by hydrocarbons, and its origin.** L. CAYEUX (Compt. rend., 1936, 203, 639—642).—The phosphatic rocks are coloured by impregnations of hydrocarbons probably produced by the decomp. of org. matter; a bituminous liquid, and a solid and gaseous product are present. The origin, disposition, and relation to petroleum deposits are discussed. R. S. B.

**Carbon dioxide eruptions from coal seams in Lower Silesia.** O. STUTZER (Econ. Geol., 1936, 31, 441—452).—Eruptions of  $\text{CO}_2$ , due to reduction of pressure by mining, from bituminous coal seams are described. Fragmentation of the coal appears to be a prerequisite for eruption. The  $\text{CO}_2$  is a constituent foreign to the coal and is probably in solid solution with the vitrain. L. S. T.

**Silica-sesquioxide ratio of clays in the characterisation of soils.**—See B., 1936, 1114.

**Iodine in Czechoslovakian soils.**—See B., 1936, 1115.

## Organic Chemistry.

**Relations of carbon and its compounds.** W. D. HARKINS (J. Org. Chem., 1936, 1, 52—64).—A review. R. S. C.

**Form and formula in organic chemistry. Comparative morphology of carbon compounds.** C. WEYGAND (Z. ges. Naturwiss., 1935, 1, 322—329; Chem. Zentr., 1936, i, 739).—A general discussion. H. N. R.

**Contributions from a study of dipole moments to the problems of organic chemistry.** C. P. SMYTH (J. Org. Chem., 1936, 1, 17—30).—A review. R. S. C.

**Oxidation of organic compounds with perchloric acid.** A. VIALARD-GOUDOU (Compt. rend., 1936, 203, 565—568).— $\text{H}_2$  is not and C is only slowly attacked by 65%  $\text{HClO}_4$  at  $200^\circ$  to give, finally, CO and  $\text{CO}_2$ .  $\text{H}_2\text{C}_2\text{O}_4$  is oxidised at  $155^\circ$  to give an equimol. mixture of CO and  $\text{CO}_2$ , which indicates that reaction occurs with  $\text{H}_2\text{C}_2\text{O}_4$  and not its decomp. products. The paraffins are oxidised at  $205$ — $210^\circ$ , whereas  $\text{C}_2\text{H}_4$ ,  $\text{C}_6\text{H}_6$ , and PhMe react at  $130$ — $145^\circ$ .

MeOH, EtOH, and AcOH are easily oxidised, but in no case is  $\text{O}_2$  liberated, indicating that decomp. of  $\text{HClO}_4$  does not precede oxidation. J. L. D.

**Optical activity and chemical structure.** P. A. LEVENE and A. ROTHEN (J. Org. Chem., 1936, 1, 76—133).—The configurative relationships of members of homologous series of the type  $\text{R}[\text{CH}_2]_n\text{CHMe}[\text{CH}_2]_m\text{X}$  ( $\text{X}=\text{Alk}$ , Ar, OH,  $\text{CO}_2\text{H}$ , CN, CHO, OH,  $\text{NH}_2$ ,  $\text{NH}_3^+$ ,  $\text{N}_3$ , Hal;  $\text{R}=\text{Alk}'$  or, occasionally, Ar';  $n$ =usually 0—2;  $m$ =0, 1, 2, etc.) are discussed; vals. of  $[\text{M}]_D^{25}$  are given. The partial rotations of the chromophoric groups can be deduced by analysis of the rotatory dispersion curves (largely unpublished). Experimental observations for aliphatic carbinols are not explicable by the theories of Boys (A., 1934, 832) or Kuhn (this vol., 454); the direction of rotation is considered to be determined by the dissymmetry of the mol. as a whole. Born's model (A., 1935, 917) fails to predict a change of sign when the distance of the chromophoric group from the asymmetric C is changed by one  $\text{CH}_2$  group. H. B.

**Action of acetyl chloride and carbon monoxide on saturated hydrocarbons in presence of aluminium chloride.** H. HOPFF, C. D. NENITZESCU, D. A. ISACESCU, and I. P. CANTUNIARI (Ber., 1936, 69, [B], 2244—2251; cf. A., 1932, 44, 514).—When  $\text{AcCl}$  and  $n\text{-C}_4\text{H}_{10}$  react in the cold in presence of  $\text{AlCl}_3$  the product is  $\text{CH}_2\text{Ac}_2$  formed by autocondensation of  $\text{AcCl}$ . At 50—60° the main product is  $\text{COMeBu}^\beta$ , also formed from  $\text{iso-C}_4\text{H}_{10}$ . In general  $\text{CO}$ , or  $\text{HCOCl}$  arising therefrom, reacts with saturated hydrocarbons in the same manner as the higher acid chlorides with the exception that it can react with the normal, unbranched chain (production of  $\text{CHMeEt}\cdot\text{CO}_2\text{H}$  from  $n\text{-C}_4\text{H}_{10}$ ), and addition at the double linking occurs in a different way. The intermediate formation of aldehydes with *tert.*-CHO explains the unusual intrusion of  $\text{CO}$  between the atoms of the C chain. The complex changes lead to homogeneous products in good yield. The following scheme is typical:  $\text{CHMe}_3 \xrightarrow{(-2\text{H})} \text{CMe}_2\cdot\text{CH}_2$ ;  $\text{CMe}_2\cdot\text{CH}_2 + \text{HCOCl} \rightarrow \text{CHO}\cdot\text{CMe}_2\cdot\text{CH}_2\text{Cl} (+2\text{H} - \text{HCl}) \rightarrow \text{Bu}^\gamma\text{CHO} \rightarrow \text{COMePr}^\beta$ .  $\text{CMe}_2\cdot\text{CH}_2 + \text{HCl} \rightarrow \text{Bu}^\gamma\text{Cl} \rightarrow \text{Bu}^\gamma\text{COCl}$ ;  $\text{CMe}_2\cdot\text{CH}_2 + \text{Bu}^\gamma\text{COCl} \rightarrow \text{COBu}^\gamma\cdot\text{CH}_2\cdot\text{CMe}_2\text{Cl} \rightarrow \text{COBu}^\gamma\cdot\text{CH}_2\text{Pr}^\beta$ . If anhyd.  $\text{AlCl}_3$ ,  $\text{HCl}$ , and  $\text{CO}$  are heated in a Cu autoclave at about 80°/100 atm., a brisk absorption of the gases occurs with production of the stable adduct  $\text{HCOCl}\cdot\text{AlCl}_3\cdot\text{CuCl}$ , which is vigorously decomposed by  $\text{H}_2\text{O}$  into  $\text{HCl}$  and  $\text{CO}$  and with  $\text{PhMe}$  in presence of anhyd.  $\text{AlCl}_3$  gives  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CHO}$  in small yield. H. W.

**Action of aluminium halides on *n*-pentane.** A. L. GLASEBROOK, N. E. PHILLIPS, and W. G. LOVELL (J. Amer. Chem. Soc., 1936, 58, 1944—1948).—Dry  $n\text{-C}_5\text{H}_{12}$  (liquid or gas +  $\text{N}_2$ ) does not react with freshly sublimed  $\text{AlCl}_3$ ; decomp. is initiated by addition of small amounts of  $\text{H}_2\text{O}$ ,  $\text{AlkCl}$  (not  $\text{ArCl}$ ), hydrated  $\text{AlCl}_3$ ,  $\text{HCl}$ , or  $\text{HBr}$  (very effective).  $\text{AlBr}_3$  alone causes decomp. and gives butanes (1.5—14.1%), isopentane (27.2—55.9%), and higher-boiling material (2.5—5.9%); added  $\text{H}_2\text{O}$  or  $\text{HBr}$  increases the reaction velocity. The extent of the decomp. depends on the concn. of  $\text{AlBr}_3$  and the time of reaction. H. B.

**Nitration of normal paraffins.** T. URBANSKI and M. SLON (Compt. rend., 1936, 203, 620—622).— $\text{C}_3\text{H}_8$  with  $\text{N}_2\text{O}_4$  at about 100° affords  $\text{Pr}^\gamma\text{NO}_2$  and  $\text{CH}_2(\text{CH}_2\text{NO}_2)_2$  in 70% yield; aldehydes and fatty acids are by-products.  $\text{CH}_4$  at about 200° gives a poor yield of  $\text{MeNO}_2$  together with polynitro-compounds and products of oxidation. J. L. D.

**Preparation of pure crystalline aliphatic hydrocarbons.** J. STRINGER and H. J. BACKER [with, in part, N. BENNING and J. LOKEMA] (Rec. trav. chim., 1936, 55, 903—914).—The following series of compounds were prepared in a pure state by standard reactions. From undecenoic acid, b.p. 164.5—165.5°, undecic acid, b.p. 122—122.5°/15 mm., the Et ester, b.p. 89—89.5°/1 mm., di-*n*-decyl ketone, m.p. 64.3—64.5°, and *n*-heneicosane, m.p. 40.3—40.5°, b.p. 172—172.5°/25 mm. From lauric acid the Et ester, b.p. 141—141.5°/8 mm., di-*n*-undecyl ketone, m.p. 69.5—69.8°, and *n*-tricosane, m.p. 47.25—47.4°, b.p. 190—191°/1.5 mm. From lauryl alcohol, m.p. 24.0—24.2°, the bromide, b.p. 130.5°/5 mm., a mixture (by the Grignard reaction with  $\text{EtOAc}$ ) of *v*-methyl- $\Delta^{\mu}$ -

pentacosane, b.p. 218.5—219.5°/3 mm., and *v*-methyl-enepentacosane, b.p. 219.5—220.5°/3 mm., and *v*-methylpentacosane, m.p. 28.8—29.0°. From erucic acid the Me ester, b.p. 217—217.5°/3 mm., and (by  $\text{MgMeI}$ )  $\beta$ -methyl- $\Delta^{\beta}$ -tricosadiene, b.p. 210.5—211.5°/3 mm., which absorbs 1  $\text{H}_2$  (Pt-black;  $\text{AcOH}$ ) at room temp. and a second  $\text{H}_2$  at 50° giving  $\beta$ -methyl-*n*-tricosane, m.p. 38.0—38.5° (lit. 42°), b.p. 207.5—208°/3 mm. From stearyl chloride, b.p. 195—195.5°/2 mm., m.p. 23.2—23.4°, *Bu*′ *n*-heptadecyl ketone, b.p. 202—203°/4.5 mm., m.p. 44.8—45.05° (semicarbazone, m.p. 78.0—78.2°), which resists Clemmensen reduction and catalytic hydrogenation, presumably owing to steric hindrance, and with  $\text{HI-P}$  gives an impure product, m.p. 21.6—22.6°. From  $(\text{CH}_2)_2\text{O}$  and  $\text{MgBu}^\gamma\text{Cl}$   $\gamma$ -methylisoamyl alcohol, b.p. 142.6—143.6°, the bromide [ $\beta\beta$ -dimethyl-*n*-butyl bromide], b.p. 58.5—59°/51 mm.,  $\gamma$ -methylisoamyl [ $\beta\beta$ -dimethyl-*n*-butyl] *n*-heptadecyl ketone (by the Cd or Mg alkyl halide), m.p. 53.45—53.75°, b.p. 212.5—213.5°/3.5 mm., and  $\beta\beta$ -dimethyl-*n*-docosane, m.p. 34.55—34.75°, b.p. 191—191.5°/4 mm. From Et nonoate, b.p. 226.5—227.5°, nonyl alcohol and bromide, b.p. 107.5°/17.5 mm.,  $\kappa$ -*n*-nonyl-*n*- $\Delta^1$ -nonadecene [from  $\text{C}_9\text{H}_{19}\cdot\text{MgBr}$  and  $\text{CH}(\text{OEt})_3$ ], b.p. 227.5—228.5°/2.5 mm., and  $\kappa$ -*n*-nonyl-*n*-nonadecane, b.p. 232.5—233°/3 mm., m.p. —6° to —5.5°. From cyclohexyl alcohol the bromide, b.p. 53°/14 mm., cyclohexyl *n*-heptadecyl ketone, b.p. 219—220°/2.5 mm., m.p. 42.6—42.85° (semicarbazone, m.p. 82.2—82.5°), and  $\alpha$ -cyclohexyl-*n*-octadecane, b.p. 207.5—208.5°/3 mm., m.p. 41.2—41.45°. R. S. C.

**Polymerisation of unsaturated gaseous hydrocarbons at atmospheric pressure and ordinary temperature by the catalytic action of phosphoric oxide and stabilisation of the liquid polymerides by hydrogenation.** E. DESPARET (Bull. Soc. chim., 1936, [v], 3, 2047—2055).—After an induction period,  $\text{C}_2\text{H}_4$ , *n*- and *iso*-butene are more or less rapidly and quantitatively adsorbed by  $\text{P}_2\text{O}_5$  on porous earthenware at room temp. and atm. pressure, and when subsequently heated at 110° the polymeride (usually mainly dimeride) is evolved. In certain cases the two processes can be effected simultaneously and the reaction can be made continuous. The polymerides are unstable, but can be stabilised by hydrogenation under known conditions. Heavy residues, C, and  $\text{H}_2\text{O}$  are not produced. H. W.

**Thermal decomposition of olefinic hydrocarbons.** B. M. MICHAÏLOV and J. A. ARBUSOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 423—426; cf. B., 1934, 792; this vol., 451).—Formation of condensation products during the pyrolysis of olefines is avoided by using a 0.5—1.0 sec. contact, and diluting to low partial pressure with steam.  $\Delta^{\alpha}$ -Pentene gave at 600° and 650°, respectively,  $\text{H}_2$  2.6 and 3.1% (by vol.),  $\text{CH}_4$  18.2 and 17.8%,  $\text{C}_2\text{H}_4$  30.9 and 32.9%,  $\text{C}_2\text{H}_6$  7.0 and 6.9%, propylene (I) 20.1 and 21.2%,  $\text{C}_3\text{H}_8$  0.5 and 0.6%, butadiene (II) 13.0 and 11.9%, with 7.7 and 5.6% of  $\Delta^{\alpha}$ - and  $\Delta^{\beta}$ -butene (III);  $\Delta^{\beta}$ -pentene gave, at 600° and 650°, respectively,  $\text{H}_2$  6.6 and 6.7%,  $\text{CH}_4$  47.9 and 40.4%,  $\text{C}_2\text{H}_4$  14.5 and 17.2%,  $\text{C}_2\text{H}_6$  5.0 and 4.1%, (I) 5.4 and 10%, (II) 15.5 and 15.6%, (III) 5.1 and 6.0;  $\Delta^{\alpha}$ -hexene gave

at 650° and 700°, respectively,  $H_2$  1.8 and 2.4%,  $CH_4$  11.2 and 11.9%,  $C_2H_4$  40.3 and 40.0%,  $C_2H_6$  2.3 and 1.4%, (I) 30.2 and 28.0%, (II) 4.3 and 5.8%, (III) 9.9 and 10.5%; 8-methyl- $\Delta^2$ -pentene at 550°, 600°, and 650°, respectively,  $H_2$  6.2, 6.9, and 7.9%,  $CH_4$  10.2, 9.3, and 8.0%,  $C_2H_4$  14.7, 17.0, and 16.3%,  $C_2H_6$  3.2, 1.2, and 0.9%, (I) 60.6, 59.3, and 58.4%,  $C_3H_8$  0.0, 0.3, and 0.2%, (II) 0.6, 0.9, 1.9%, (III) 3.5, 4.1, and 5.3%, and isobutene 1.0, 1.0, and 1.1%.

R. C. M.

**Resolution of  $\alpha\gamma$ -trimethylallyl alcohol into optically active forms.** D. I. DUVEEN and J. KENYON (J.C.S., 1936, 1451—1453).— $\alpha\gamma$ -Trimethylallyl alcohol was converted into its *p*-xenylylurethane, m.p. 65°, and *H* phthalate, m.p. 81.5°; the *brucine* salt, m.p. 143—144°,  $[\alpha]_{5893} -17.0^\circ$  in  $CHCl_3$ , of this was hydrolysed (HCl) to the *d*-*H* phthalate, m.p. 43—44°,  $[\alpha]_{5893} +14.5^\circ$  in  $CHCl_3$ , converted (NaOH) into the *d*-alcohol, b.p. 129°, 43°/17 mm.,  $[\alpha]_{5893} +8.02^\circ$  in  $CHCl_3$  (*Ac*, b.p. 51°/15 mm., and *Bz*, b.p. 139°/19 mm., derivatives), reduced ( $H_2$ -Ni) to *d*-CHMeBu $\alpha$ -OH. The *l*-*H* phthalate, m.p. 44°,  $[\alpha]_{5893} -12.8^\circ$  in  $CS_2$ , obtained by HCl hydrolysis of its *strychnine* salt, m.p. 152° (decomp.),  $[\alpha]_{5893} -20.64^\circ$  in  $CHCl_3$ , was hydrolysed (NaOH) to the *l*-alcohol, b.p. 129°, 43°/18 mm.,  $\alpha_D^{20} -2.13^\circ$  (*l*, 0.5).

F. R. G.

**Condensation of butan- $\beta$ -one with aldehydes of the type,  $CHRR'\cdot CHO$ .** S. G. POWELL and M. M. BALDWIN (J. Amer. Chem. Soc., 1936, 58, 1871—1872).—The ketols obtained from COMeEt and CHMeEt $\cdot$ CHO (obtained by dehydrogenation of CHMeEt $\cdot$ CH $_2$  $\cdot$ OH with a Cu-Cr-Ba oxide catalyst), CHEt $_2$  $\cdot$ CHO, and CHEtBu $\alpha$  $\cdot$ CHO (I) in dil. KOH are dehydrated and then reduced (methods: A., 1925, i, 7; 1933, 492) to  $\zeta$ -methyloctan- $\gamma$ -ol, b.p. 81—83°/15 mm.,  $\zeta$ -ethyloctan- $\gamma$ -ol, b.p. 90—92°/20 mm., and ethyldecan- $\gamma$ -ol, b.p. 119—120°/18 mm., respectively, which are oxidised (*loc. cit.*) to  $\beta$ -methylvaleric,  $\beta$ -ethylvaleric, and  $\beta$ -ethylheptioic acid (II), b.p. 135°/25 mm., 236°/760 mm., respectively (piperazine salts, m.p. 129°, 134°, and 100°, respectively).  $\beta$ -Ethylhexyl alcohol [prepared by addition of Na and AcOH to (I) in  $Et_2O$ +aq.  $MgSO_4$  so that the mixture is slightly alkaline] and  $PBr_3$  give the bromide (III), which with NaCN and subsequent hydrolysis affords (II).  $\gamma$ -Ethylctoic acid, b.p. 253—256°/760 mm. (piperazine salt, m.p. 110°), is prepared (usual method) from (III) and  $CH_2(CO_2Et)_2$ . The piperazine salt of  $\gamma$ -methylhexoic acid has m.p. 109°.

H. B.

**Alkylation. V. Formation of ethyl ether from ethyl chloride and some theoretical deductions.** V. A. ISMAILSKI and B. V. POPOV (Bull. Soc. chim., 1936, [v], 3, 2028—2037).—A solution of *m*- $NH_2\cdot C_6H_4\cdot SO_3H$  (1 mol.), NaOH (2 mols.), anhyd.  $Na_2CO_3$  (1.57 mols.), and EtCl (4.08 mols.) in 96% EtOH is heated in an autoclave at 125° during 13 hr. and the EtCl used,  $NH_4Et\cdot C_6H_4\cdot SO_3H$ ,  $NEt_2\cdot C_6H_4\cdot SO_3H$ , and  $Et_2O$  formed are determined in the mixture. Secondary changes involve 43.4% of the EtCl taken; of this, 56% is used in the production of  $Et_2O$  and 44% in that of EtOH. The schemes  $EtCl+NaOH \rightarrow NaOEt+H_2O$  and  $EtCl+NaOEt \rightarrow Et_2O+NaCl$  are rejected, since in the aq.

alcoholic medium the equilibrium is almost completely displaced towards the left. More probably, the change involves the formation of oxonium compounds, transformed by NaOH into the oxonium bases, which decompose into  $Et_2O+H_2O$  and  $EtOH+H_2O$ , respectively, and is thus analogous to Hofmann's reaction between amines and alkyl halides. The intermediate formation of oxonium compounds explains also the production of alkynes from alkyl halides and alcohols and the prep. of  $Et_2SO_4$  from  $Et_2O$  and  $ClSO_3H$ .

H. W.

**Tertiary alkyl ethers.** T. W. EVANS and K. R. EDLUND (Ind. Eng. Chem., 1936, 28, 1186—1188).—The direct addition of olefines to alcohols by the Reychler reaction (A., 1907, 275) has been elaborated.  $CMe_2\cdot CHMe$  and EtOH with  $H_2SO_4$  under pressure at 60° give an equilibrium mixture containing 40% of Et *tert*-amyl ether, b.p. 101—102°. The following are thus prepared: Me, b.p. 55°, Et, b.p. 73°,  $Pr^i$ , b.p. 87—88°, Bu $^i$ , b.p. 123—124°, Bu $^s$ , b.p. 114°, sec.-Bu, b.p. 114—115°, Ph, b.p. 185—186°, and  $CH_2Ph$ , b.p. 82—83°/8 mm., Bu $^i$  ether; Bu $^i$  isoamyl ether, b.p. 138—140°: Me, b.p. 86—87°, and  $Pr^i$ , b.p. 114—115°, *tert*-amyl ether; Me *tert*-hexyl ether, b.p. 113°; ethylene glycol Bu $^i$ , b.p. 153°, Bu $_2$ , b.p. 171°, Me Bu $^i$ , b.p. 131—132°, Et Bu $^i$ , b.p. 148°, Bu $^s$  Bu $^i$ , b.p. 83°/20 mm., and *tert*-amyl, b.p. 50—55°/3 mm., ether;  $\alpha\beta$ -propylene glycol Bu $^i$  ether, b.p. 151—153°; glycerol Bu $^i$ , b.p. 93—94°/5 mm., and Bu $_2$  ether, b.p. 80—82°/4 mm.; diethylene glycol Bu $^i$  ether, b.p. 72°/2 mm. The equilibrium reached varies with the olefine used.

R. F. P.

**Bromonitromethiononic acid.** H. J. BACKER (Rec. trav. chim., 1936, 55, 915—920).— $K_2$  nitromethionate (I) and Br- $H_2O$  at 65° give bromonitromethiononic acid,  $+4H_2O$ , m.p. about 65°, and  $+2H_2O$  (retained in vac. over  $P_2O_5$ ), m.p. 90—91° (decomp.) [*distrychnine*,  $+H_2O$ , Ba,  $+3H_2O$ ,  $K_2$ ,  $Tl_2$ , and dibrucine,  $+6H_2O$ , phototropic, salts], which regenerates (I) with  $K_2S_2O_3$ . Dibrucine chloromethionate is also phototropic. Crystallographic data [P. TERPSTRA] are given for three of these salts.

R. S. C.

**Addition of sodium hydrogen sulphite to alkylene oxides.** W. M. LAUER and A. HILL (J. Amer. Chem. Soc., 1936, 58, 1873—1874; cf. Fromm *et al.*, A., 1928, 868).— $(CH_2)_2O$  with conc. aq.  $NaHSO_3$  and  $KHSO_3$  gives Na (I), m.p. 192—194°, and K (II), m.p. 191—193°,  $\beta$ -hydroxyethanesulphonate, respectively, acetylated (method: this vol., 316) to Na and K, m.p. 258—260°,  $\beta$ -acetoxyethanesulphonate, respectively. Na  $\beta$ -myristoyloxyethanesulphonate is prepared from (I) and myristoyl chloride. (I) and (II) with  $PCl_5$  afford  $CH_2Cl\cdot CH_2\cdot SO_2Cl$ , b.p. 86—88°/13 mm.  $NH_4$   $\beta$ -chloroethanesulphonate and conc. aq.  $NH_3$  at 105° give taurine, which with  $KNO_2$ +AcOH yields (II).

H. B.

**Polysulphones from acetylenes and sulphur dioxide.** L. L. RYDEN and C. S. MARVEL (J. Amer. Chem. Soc., 1936, 58, 2047—2050; cf. this vol., 186).— $CH_2CR$  [ $R=Me$ , Et (I),  $Pr^i$  (II), Bu $^i$ , *n*-amyl, and Ph (III)] with  $SO_2$  in EtOH followed by paracet-aldehyde (must contain peroxide) give polysulphones, decomp. 250—260°, 210—215° (Ia), 203—208° (IIa),

195–205°, 164–170°, and 250–275° (IIIa), respectively. CMe·CR (R=Me, Pr, Ph), (:C·CO<sub>2</sub>Et)<sub>2</sub>, and allene do not similarly react. The presence of ·CR:CH·SO<sub>2</sub>· in (Ia), (IIa), and (IIIa) is established by oxidation (aq. KMnO<sub>4</sub>) to EtCO<sub>2</sub>H, PrCO<sub>2</sub>H, and BzOH, respectively. Hydrolysis (aq. NaOH) of (IIIa) affords CPhMe (trace), CH<sub>2</sub>Ph·SO<sub>2</sub>Me (IV) (8%), BzOH (20%) and Na<sub>2</sub>SO<sub>3</sub> (50%) (the remainder of the S is in the tarry product formed); the formation of (IV) indicates that part of (IIIa) must be [·SO<sub>2</sub>·CPh:CH·SO<sub>2</sub>·CPh:CH·]<sub>n</sub>. (IIa) is similarly hydrolysed to COMePr<sup>a</sup> (trace). (IIa) could not be reduced (H<sub>2</sub>, Pt, dioxan, room temp.). (IIa) heated to 200–215° gives 50–60% of SO<sub>2</sub>; in boiling dioxan SO<sub>2</sub> (about 50%) and a little of a compound, C<sub>10</sub>H<sub>16</sub>O<sub>2</sub>S, m.p. 88°, are formed. SO<sub>2</sub> (62·73%) is liberated when (IIIa) is heated at 140°/45 min.

H. B.

**Chemistry of the Claisen condensation.** F. ARNDT and B. EISTERT (Ber., 1936, 69, [B], 2381–2393).—The fundamental basis of the theoretical treatment of compounds with multiple linkings is the conception of the intermediate condition identical with that of resonance between electromeric limiting states and to which the term mesomerism has been applied. Also the inductive effect plays a part. The essentials for the Claisen reaction are the ester (amide) component (I) R·CO<sub>2</sub>Et and the methylene component (II) CH<sub>2</sub>R·CO·R, which must contain CH<sub>2</sub> vicinal to CO and in which CO may be present in CO<sub>2</sub>Et. The alkaline condensing agent causes a possibly minute fraction of (II) to release a proton from CH<sub>2</sub>, thus giving EtOH, NH<sub>3</sub>, or H and forming the ionic alkali metal salt of (II). This conception agrees with that of Scheibler in so far as (II) [not (I)] is concerned in this preliminary stage, but differs in that it does not assume the production of an enolate, but of a compound in which Na functions as cation. Na is therefore not directly concerned with any of the subsequent reactions, and the question of the enolic structure of the anion is subsidiary. Such an anion is regarded as being in the intermediate condition between [·CHR·CO·R]Na<sup>+</sup> (III) and [CHR·CO·R]Na<sup>+</sup>. Reaction occurs between (I) and (III) which contains the unused pair of electrons at C. (I) is also capable of mesomerism and can react in the electromeric conditions R·CO·OEt and OEt·CR·O· (IV). The initial step in the Claisen condensation therefore consists in the entry of the free pair of electrons of (III) into the octet vacancies of the CO·C atom of (I) in form (IV) giving the anionic product, [COR·CHR·CR(OEt)·O]Na<sup>+</sup>. The formation of this product is reversible and not detectable experimentally, and the equilibrium lies far on the left. Union of the second CO to the original CH<sub>2</sub>·C atom of (II) causes this C atom to be placed under the influence of two pronouncedly positive vicinal C atoms, and consequently the remaining proton is much less firmly bound than was originally the case. It therefore unites with the anionic [OEt]· to form EtOH, thereby giving the anion [COR·CR·CR·O]Na<sup>+</sup>, which is almost completely enolic, since it thereby contains a conjugated system. The striving to build such a system must be regarded as the most important and controlling factor of the whole Claisen condensation,

since it brings the feature of irreversibility among a no. of reversible changes, many of which occur in only a small degree. This conception renders obvious the need of CH<sub>2</sub> as well as CO in (II) and the impossibility of the replacement of CO by SO<sub>2</sub>; although the proton-loosening action of SO<sub>2</sub> is > that of CO it cannot function as conjugation partner, since it does not contain true double linkings, but contains O atoms only in semipolar union. It also explains why (II) must contain at least two H attached to active C, since these are eliminated consecutively. Related reactions (aldol condensation, Perkin's and Knoevenagel's syntheses) are discussed. Other views of the course of ester and aldol condensation (enolisation hypothesis, the "intermediate substance" rule, and the hypothesis of the tautomerism, enolate organo-metallic compound) are reviewed.

H. W.

**Twitchell's reagent.** I. Twitchell's reagent as promoter of esterification. J. N. ZAGANIARIS and G. A. VARVOGLIS (Ber., 1936, 69, [B], 2277–2282).—The hydrolytic and esterifying actions of Twitchell's reagent are in a dynamic equilibrium displaced towards the ester side. Reaction is usually effected with a three-fold excess of one component and 2·3 wt.-% of catalyst calc. on that of the mixture. Heating of the mixture is unnecessary and frequently disadvantageous. Aliphatic acids give good yields of esters with primary, sec., and polyhydric aliphatic and fatty-aromatic alcohols, but not with *tert.* alcohols or phenols, with which little action takes place. Aromatic carboxylic, phenolic, and unsaturated fatty-aromatic acids do not react or give very moderate yields. The following interactions are described. AcOH with MeOH, EtOH, Pr<sup>n</sup>OH, *iso*-(I) and *tert.*-amyl alcohol, (CH<sub>2</sub>·OH)<sub>2</sub>, glycerol, CH<sub>2</sub>Ph·OH, PhOH; CCl<sub>3</sub>·CO<sub>2</sub>H with EtOH; Pr<sup>n</sup>CO<sub>2</sub>H with EtOH and (I); EtOH with palmitic, oleic, and tartaric acid, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, BzOH, CHPh:CH·CO<sub>2</sub>H, *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>, and *p*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>; PhOH and EtOH; *o*-OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H and MeOH.

H. W.

**Basic acetates of lead.**—See this vol., 1464.

**Enzymic dehydration of trideuteroacetic acid.**—See this vol., 1418.

**Reaction kinetics and the Walden inversion.** W. A. COWDREY, E. D. HUGHES, and C. K. INGOLD (Nature, 1936, 138, 759).—The hydrolysis of *l*-α-bromopropionic acid to give lactic acids of different optical sign is cited as an example connecting optical inversion with structure and conditions. The optical sign depends on whether conditions favour a uni- or a bi-mol. reaction.

L. S. T.

**Effect of varying conditions in the catalytic hydrogenation of fatty oils on the nature of the reaction product.** III. H. I. WATERMAN, C. VAN VLODRUP, and J. A. PEZY (Rec. trav. chim., 1936, 55, 854–858; cf. A., 1933, 258).—Colloidal Ni, prepared by hydrogenation of Ni(CO)<sub>4</sub> in oil, allows rapid hydrogenation of unsaturated aliphatic esters and fatty oils at 50°/1 atm., without destruction of vitamin-A. Hydrogenation follows the "homogeneous reaction scheme" (saturation first of the most unsaturated centres).

R. S. C.

**Mechanism of the elaidinisation reaction.** S. H. BERTRAM (Chem. Weekblad, 1936, 33, 637—638).—The isomerisation of oleic and elaidic acids in presence of 0.5% of Se at 150° is termol., the Se forming an intermediate complex, in accordance with the hypothesis put forward (this vol., 189). S. C.

**Optical properties of fermentation lactic acids.**—See this vol., 1419.

**Enzymic racemisation of optically active lactic acid.**—See this vol., 1560.

**Polarographic analysis in the study of keto-enol tautomerism.** G. SEMERANO and A. CHISINI (Gazzetta, 1936, 66, 504—509).—The different reduction potentials at a dropping Hg cathode of the keto- and enol forms of a substance can be used to determine the amounts of the two forms in a mixture. By this means the keto-enol tautomerism of  $\text{CH}_3\text{Ac}\cdot\text{CO}_2\text{Et}$  and of  $\text{CH}_2\text{Ac}_2$  has been investigated.

O. J. W.

**Doubly conjugated system in  $\alpha$ - and  $\beta$ -licanic acids.** R. S. MORRELL and W. R. DAVIS (J.C.S., 1936, 1481—1484).— $\alpha$ - and  $\beta$ -Licanic acids (Brown *et al.*, A., 1935, 607) present in oiticica oil combine with maleic anhydride in  $\text{CO}_2$  at 85° to give, respectively, the  $\alpha$ -additive compound (I), m.p. 79° [ $H_4$ -derivative (Adams), m.p. 111°], and the  $\beta$ -additive compound (II), m.p. 97—98° ( $H_4$ -derivative, m.p. 72—73°). Oxidation of (I) with 5%  $\text{KMnO}_4$ - $\text{Na}_2\text{CO}_3$  at 0° affords  $\gamma$ -ketoazelaic acid (III) (34% yield) and only a trace of valeric acid (IV) (p-bromophenacyl ester, m.p. 73°); ozonolysis of (II) gives mainly (IV) and a substance, m.p. 99—105°. As in the elaeostearic system the  $\Delta^{\alpha,\beta}$ -double linkings are involved in the formation of (I) and the  $\Delta^{\beta,\gamma}$ -linkings in (II), thus suggesting the *X-trans-trans-cis*-Y $\cdot\text{CO}_2\text{H}$  structure for  $\alpha$ - and *X-cis-cis-trans*-Y $\cdot\text{CO}_2\text{H}$  for  $\beta$ -licanic acid. J. W. B.

**Sensitive reaction for oxalic acid.** O. CARLETTI (Boll. Chim. farm., 1936, 75, 498—499).—A reddish-violet colour, changing to blue, is given by  $\text{H}_2\text{C}_2\text{O}_4$  ( $6.3 \times 10^{-6}$  g.) with resorcinol in presence of glycerol (1 drop) and  $\text{H}_2\text{SO}_4$ .

F. O. H.

**Resorcinol reaction of oxalic acid.** M. PESEZ (Bull. Soc. chim., 1936, [v], 3, 2072—2074; cf. this vol., 745).—The oxalate solution is acidified with  $\text{H}_2\text{SO}_4$  and reduced with sheet Zn in presence of  $\text{CuSO}_4$ . A pale blue colour which becomes intense at 100° is developed when 4 drops of this solution are mixed with 2 c.c. of conc.  $\text{H}_2\text{SO}_4$  and 2 drops of Denigès' resorcinol reagent. The reaction appears sp. for  $\text{C}_2\text{O}_4^{2-}$  and is not affected by the presence of  $\text{OCl}^-$ ,  $\text{ClO}_3^-$ ,  $\text{BrO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{NO}_3^-$ , or  $\text{CrO}_4^{2-}$ . It is modified in presence of  $\text{Br}^-$  or  $\text{I}^-$ .  $\text{C}_2\text{O}_4^{2-}$  interferes with the author's (*loc. cit.*) or Denigès' test for tartaric acid and is removed by pptn. as  $\text{CaC}_2\text{O}_4$  in  $\text{AcOH}$  previously to the reduction.

H. W.

**[Activated form of oxalic acid.]** E. SCHROER (Ber., 1936, 69, [B], 2243; cf. this vol., 1361; Krauss *et al.*, A., 1930, 577).— $\text{HCO}_2\text{H}$  cannot be regarded as the "active form" of  $\text{H}_2\text{C}_2\text{O}_4$ , with which it has only the strongly reducing properties in common. It has not the more important ability to reduce mol.  $\text{O}_2$  to  $\text{H}_2\text{O}_2$  and to lose activity slowly.

H. W.

**Oxalato complex compounds of tervalent manganese.**—See this vol., 1477.

**Diene syntheses and selenium dehydrogenation in their importance for the development of organic chemistry.** O. DIELS (Ber., 1936, 59, [A], 195—208).—A lecture.

**Condensation of ethyl  $\alpha$ -bromoisobutyrate with *n*-alkylmalonic esters. Structure of the lupin alkaloids.** H. N. RYDON (J.C.S., 1936, 1444—1448).—In the condensation of  $\text{CMeR}\cdot\text{Br}\cdot\text{CO}_2\text{Et}$  with  $\text{CRNaX}\cdot\text{CO}_2\text{Et}$  to give  $\text{CO}_2\text{Et}\cdot\text{CMeR}\cdot\text{CRX}\cdot\text{CO}_2\text{Et}$  and  $\text{CO}_2\text{Et}\cdot\text{CHR}\cdot\text{CH}_2\cdot\text{CRX}\cdot\text{CO}_2\text{Et}$ , the formation of the latter isomeride is greater when  $\text{R}=\text{R}'=\text{Me}$  instead of  $\text{H}$ , is increased as  $\text{X}$  changes from  $\text{Ac}$  to  $\text{CN}$  and then  $\text{CO}_2\text{Et}$ , and decreased as  $\text{R}$  changes from  $\text{H}$  to  $\text{Et}$ , then  $\text{Pr}^n$ ,  $\text{Bu}^n$ , and *n*-amyl. Hydrolysis of condensation products of the above type leads to *cis*- $\alpha$ -methyl- $\alpha'$ -ethyl-, m.p. 116°, and - $\alpha'$ -*n*-propylglutarimide, m.p. 78°;  $\alpha\alpha$ -dimethyl- $\alpha$ -*n*-butylsuccinic and -glutaric acid, oils; *cis*- $\alpha$ -methyl- $\alpha'$ -*n*-amylglutaric acid, m.p. 76°. In order to confirm the structure of the imide (I) on which the structure of anagyrene was based by Ing (A., 1933, 727), this was synthesised from  $\text{OH}\cdot\text{CH}_2\cdot\text{CHMe}\cdot\text{CO}_2\text{Et}$ , which with  $\text{PBr}_3$  in  $\text{CHCl}_3$  or  $\text{PCl}_5$  yields respectively, *Et*  $\beta$ -bromo-, b.p. 91—93°/19 mm., and  $\beta$ -chloro-isobutyrate, b.p. 56—58°/10 mm., either of which with *Et* *n*-amylmalonate,  $\text{NaI}$ , and  $\text{NaOEt}$  in  $\text{EtOH}$  gives *Et*  $\alpha'$ -carbethoxy- $\alpha$ -methyl- $\alpha$ -*n*-amylglutarate, b.p. 140—145°/3 mm., hydrolysed to  $\alpha$ -methyl- $\alpha'$ -*n*-amylglutaric acid, m.p. 74—75° [imide (II), m.p. 71—72°].  $\text{CO}_2\text{Et}\cdot\text{CMe}_2\cdot\text{CH}(\text{CN})\cdot\text{CO}_2\text{Et}$  with *n*- $\text{C}_5\text{H}_{11}\text{Br}$  and  $\text{NaOEt}$  in  $\text{EtOH}$  gives *Et*  $\alpha$ -cyano- $\alpha'$ - $\alpha'$ -dimethyl- $\alpha$ -*n*-amylsuccinate, b.p. 187—191°/22 mm., 137°/0.9 mm., hydrolysed ( $\text{KOH}$ ) to  $\alpha\alpha$ -dimethyl- $\alpha$ -*n*-amylsuccinic acid, m.p. 119° [imide (III), m.p. 64—65°]. Ing's synthetic imide (*loc. cit.*) is a mixture of (II) and (III). (I) has the amended m.p. 58—60° and, although non-homogenous, is regarded as identical with (II), confirming the accepted structures of the lupin alkaloids.

F. R. G.

**Preparation in a high state of purity of long-chain compounds in view of the determination of their energy contents. II. Brassidic acid type.** L. J. P. KEFFLER (J.S.C.I., 1936, 55, 331—333r).—Repeated crystallisations of brassidic acid (as well as other acids of the *trans*-type) do not remove certain impurities when the usual technique is followed. Systematic fractional crystallisation at one const. temp. should be carried out, starting with an amount of solvent many times that which would be just sufficient to dissolve completely the acid at a temp. not far removed from the b.p. of the pure solvent. This amount depends on the nature of the acid to be purified and on the nature and concn. of the impurities admixed with it.

**Determination of ascorbic acid.**—See this vol., 1567.

**Reduction of inactivated *l*-ascorbic acid.** I. A. GOLJANICKI and I. S. BELONOSOV (Compt. rend. Acad. Sci. U.R.S.S., 1936, 4, 15—16).—*l*-Ascorbic acid, inactivated by heat and  $\text{O}_2$ , is regenerated to the extent of 15—17% by addition of sugar and yeast

or, better, also of peroxidase, the necessary 2 H being derived from the change,  $\text{CHAc}(\text{OH})_2 \rightarrow \text{AcCO}_2\text{H}$ .

R. S. C.

**Photochemical reactions of iron gluconates.**—See this vol., 1473.

**Colour reactions of keturonic acids and a colour test differentiating  $\alpha$ - and  $\beta$ -glucosides.** F. SHEPPARD and M. R. EVERETT (Proc. Soc. Exp. Biol. Med., 1936, 34, 7—9).—The results are given of the application of various colour tests to the products obtained by oxidising polyhydric alcohols, sugars, and sugar derivatives in 1% aq. solution with Br for 6 weeks at 25°.

W. O. K.

**Pectin problem.** F. EHRLICH (Festschr. Techn. Hochsch. Breslau, 1935, 129—141; Chem. Zentr., 1936, i, 788—789).—Cold alkaline hydrolysis of citrus and apple pectin yields *gelpectolic acid*,  $\text{C}_{24}\text{H}_{32}\text{O}_{24}$ , which differs in many ways from pectolic acid, into which it is converted by long boiling with  $\text{H}_2\text{O}$ . A structure is suggested.

H. N. R.

**Kinetics of sulphonium compounds.**—See this vol., 1469.

**$\alpha$ - and  $\beta$ -Sulphovaleric acids with a branched chain.** H. J. BACKER and D. VAN DER VEEN (Rec. trav. chim., 1936, 55, 887—898).— $\text{CHPr}^{\beta}(\text{CO}_2\text{H})_2$ , m.p. 93°, and  $\text{SO}_3$  at <0° give an oily mixed *anhydride*, which on gentle warming decomposes exothermally to  $\text{CO}_2$  and  $\alpha$ -sulphoisovaleric acid,  $+\text{H}_2\text{O}$ , m.p. 68° [*Ba*,  $+\text{H}_2\text{O}$ ,  $+6$  and  $+8\text{H}_2\text{O}$  (not obtained pure), *Ca*,  $+2\text{H}_2\text{O}$ , *Pb*,  $+2\text{H}_2\text{O}$ , *Tl*, *dibrucine*, and *distrychnine* salts], also obtained with  $\text{OH}\cdot\text{CHPr}^{\beta}\cdot\text{CO}_2\text{H}$  from  $\text{CHPr}^{\beta}\text{Br}\cdot\text{CO}_2\text{NH}_4$  and  $(\text{NH}_4)_2\text{SO}_3$ . The *brucine H* or *diquinine* salt leads to the *d-acid*,  $[\text{M}]_D -3^\circ$  (*Ba* salt,  $[\text{M}]_D +15^\circ$ ), racemised by NaOH slowly at 100° and more rapidly at 165° and by HCl at 165°.  $\alpha$ -Sulpho- $\alpha$ -methyl-*n*-butyric acid (I),  $+\text{H}_2\text{O}$ , m.p. 83° (*Pb*,  $+2\text{H}_2\text{O}$ , *Ba*,  $+3\text{H}_2\text{O}$ , *Tl*, and *distrychnine* salts), is obtained in poor yield from  $\text{SO}_3$  and  $\text{CMeEt}(\text{CO}_2\text{H})_2$  by way of the mixed *anhydride* or with  $\text{OH}\cdot\text{CMeEt}\cdot\text{CO}_2\text{H}$  from  $\text{CMeEtBr}\cdot\text{CO}_2\text{NH}_4$  and in 34% yield from  $\text{CHMeEt}\cdot\text{CO}_2\text{H}$  and  $\text{SO}_3$ , and is resolved by the *brucine H*,  $+\text{H}_2\text{O}$ , salt to the *l-acid*,  $[\text{M}]_D -36^\circ$  (*Ba* salt,  $[\text{M}]_D -27^\circ$ ), and by the *diquinine* salt,  $+5\text{H}_2\text{O}$ , to the *d-acid*.  $\text{CMe}_2\cdot\text{CH}\cdot\text{CH}_2\text{M}$  ( $\text{M}=\text{K}$  or  $\text{NH}_4$ ) and  $\text{K}_2\text{S}_2\text{O}_7$  at 90° give  $\beta$ -sulphoisovaleric acid (*Ba* and *Pb* salts,  $+\text{H}_2\text{O}$ ). When  $\text{CHMe}\cdot\text{CMe}\cdot\text{CHO}$  and  $\text{SO}_3$  react at 0° and are then left with Br in light,  $\beta$ -sulpho- $\alpha$ -methyl-*n*-butyric acid (cf. lit.) (II) (*Ba*,  $+\text{H}_2\text{O}$ , *Pb*, *distrychnine*,  $+2\text{H}_2\text{O}$ , and *brucine H*,  $+3\text{H}_2\text{O}$ , salts) is obtained.  $\text{OH}\cdot\text{CMeEt}\cdot\text{CN}$  and hot HCl give  $\alpha$ -hydroxy- $\alpha$ -methylbutyric acid, m.p. 72—73°, which at 140—150° gives a mixture of angelic and tiglic acids. K tigliate and  $\text{K}_2\text{S}_2\text{O}_7$  at 90° give the *stereoisomeride* (III) of (II) (*Ba*,  $+0.5\text{H}_2\text{O}$ , *Pb*,  $+\text{H}_2\text{O}$ , and *dibrucine*,  $+8\text{H}_2\text{O}$ , salts). The *diquinine* salt of (II) gives the *l-acid*,  $[\text{M}]_D -26^\circ$  (*Ba* salt,  $[\text{M}]_D -40.5^\circ$ ). The *diquinine* salt,  $+3\text{H}_2\text{O}$ , of (III) gives the *d-acid*,  $[\text{M}]_D +37^\circ$  (*Ba* salt,  $[\text{M}]_D -22^\circ$ ).  $\text{CH}_2\cdot\text{CEt}\cdot\text{CO}_2\text{K}$  and  $\text{K}_2\text{S}_2\text{O}_7$  at 90° give  $\alpha$ -sulphomethyl-*n*-butyric acid (IV) (*Ba* and *Pb* salts,  $+\text{H}_2\text{O}$ ), the *diquinine* salt,  $+4.5\text{H}_2\text{O}$ , of which gives the *d-acid*,  $[\text{M}]_D +24^\circ$  (*Ba* salt,  $[\text{M}]_D +7.5^\circ$ ).  $\text{CH}_2\text{Br}\cdot\text{CMe}_2\cdot\text{CO}_2\text{NH}_4$  and

$(\text{NH}_4)_2\text{SO}_3$  give  $\beta$ -sulphopivalic acid (*Ba* salt,  $+0.5\text{H}_2\text{O}$ ). (II), (III), and (IV) resist racemisation, since the activity does not depend on a H adjacent to  $\text{SO}_3\text{H}$ .

R. S. C.

**Trideuteroacetdeuterualdehyde.** J. E. ZANETTI and D. V. SICKMAN (J. Amer. Chem. Soc., 1936, 58, 2034—2035; cf. this vol., 316).— $\text{C}_2\text{D}_2$  passed into  $\text{D}_2\text{O}-\text{D}_3\text{PO}_4-\text{HgSO}_4$  gives *trideuteroacetdeuterualdehyde* (I),  $\text{CD}_3\cdot\text{CDO}$ , b.p. 20.5°/756 mm., m.p. —121.7°, v.p. 327 mm. at 0°, and *paratrideuteroacetdeuterualdehyde* (II), b.p. 124—125°/753 mm., m.p. 13.7°. (I) polymerises fairly readily to (II) when kept in sealed tubes.

H. B.

**Mechanism of carbohydrate oxidation. XXII. Preparation and reactions of glyceraldehyde diethyl mercaptal.** H. W. ARNOLD and W. L. EVANS (J. Amer. Chem. Soc., 1936, 58, 1950—1952).—Glyceraldehyde,  $\text{EtSH}$ , and cold conc. HCl give *glyceraldehyde Et<sub>2</sub> mercaptal* (I), b.p. 156—158°/3 mm., and a little of a compound, m.p. 126—127.5° [probably formed by condensation of several mols. of (I)]. (I) and  $\text{CPh}_3\text{Cl}$  in  $\text{C}_5\text{H}_5\text{N}$  afford the  $\beta$ - $\text{CPh}_3$  ether, m.p. 100—101° ( $\alpha$ -Ac, m.p. 93—94°, and  $\alpha$ -Bz, m.p. 90—91°, derivatives); the  $\text{CPh}_3$  group could not be removed (various procedures) from these compounds. Acetylation ( $\text{Ac}_2\text{O}-\text{C}_5\text{H}_5\text{N}$ ) of (I) and treatment of the resulting viscous oil with  $\text{HgCl}_2+\text{CdCO}_3$  in aq.  $\text{COMe}_2$  gives  $\alpha\beta$ -diacetylglyceraldehyde, b.p. 154—156°/3 mm., which with  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{NH}_2$  in aq.  $\text{EtOH}-\text{HCl}$  affords (probably)  $\beta$ -acetylglucaldehyde-*p*-nitrophenyllosazone, m.p. 282—286° (block) (darkens at 235—240°) (all m.p. except this are corr.), and with  $\text{MeOH}-\text{NH}_3$  followed by 2:4- $(\text{NO}_2)_2\text{C}_6\text{H}_3\cdot\text{NH}\cdot\text{NH}_2$ , yields glyceraldehyde-2:4-dinitrophenylhydrazone.

H. B.

**Mechanism of carbohydrate oxidation. XXI. Synthesis of glucosidoglyceraldehyde derivatives.** H. W. ARNOLD and W. L. EVANS (J. Amer. Chem. Soc., 1936, 58, 1890—1894).—Glyceraldehyde benzylcycloacetal (I) (Fischer and Baer, A., 1932, 364), acetobromo-*d*-glucose,  $\text{Ag}_2\text{CO}_3$ , and “Drierite” in  $\text{C}_6\text{H}_6$  give 50% of  $\beta$ - $\beta'$ -*d*-glucosidoglyceraldehyde benzylcycloacetal tetra-acetate, m.p. 172—173° (corr.),  $[\alpha]_D^{25} -19.9^\circ$  in  $\text{CHCl}_3$ , cleaved by  $\text{H}_2+\text{Pd}$ -black in MeOH to the amorphous  $\beta$ - $\beta'$ -*d*-glucosidoglyceraldehyde tetra-acetate (II), m.p. 63°,  $[\alpha]_D^{25} -15.5^\circ$  in  $\text{CHCl}_3$ , which reduces cold Fehling's solution. Cryst. derivatives (Ac, Bz, phenylhydrazones) of (II) could not be prepared. (II) with  $\text{C}_5\text{H}_5\text{N}$  at 135—140° (bath) followed by  $\text{Ac}_2\text{O}$  affords a syrup containing 8—9% of  $\beta$ -*d*-glucosidodihydroxyacetone penta-acetate (A., 1935, 477), determined as the *p*-nitrophenylhydrazone.  $\beta$ - $\beta'$ -*l*-Arabinosidoglyceraldehyde benzylcycloacetal tri-acetate, m.p. 142—143° (corr.),  $[\alpha]_D^{25} +4.2^\circ$  in  $\text{CHCl}_3$ , is obtained (as above) in 7% yield from (I) and acetobromo-*l*-arabinose. Dimeric glyceraldehyde diacetate and  $\text{TiCl}_4$  in  $\text{CHCl}_3$  at room temp. give 81—87% of *acetochloroglyceraldehyde*, m.p. 174—175° (corr.), which with  $\text{CH}_2\text{Ph}\cdot\text{OH}+\text{Ag}_2\text{CO}_3$  affords a mixture of isomeric glyceraldehyde benzylcycloacetal acetates, m.p. 109—110° (corr.) (small amount) and 141—142° (corr.) (Fischer and Baer, loc. cit.).

H. B.

**Photochemical peroxide formation. IV. Oxidation of acetone by molecular oxygen in ultra-**

violet light. Photochemical production of peracetone. R. CANTIENT (Ber., 1936, 69, [B], 2282—2285; cf. this vol., 1091).—COMe<sub>2</sub> is converted by O<sub>2</sub> in ultra-violet light, unfiltered or filtered through glass, into its *peroxide* (I), the formation of which is retarded by addition of H<sub>2</sub>O. Since H is not produced by photolysis of COMe<sub>2</sub> and dry COMe<sub>2</sub> is transformable into (I), the production of H<sub>2</sub>O<sub>2</sub> is excluded. (I) is unstable in ultra-violet light, its rate of decomp. increasing with its concn. The following scheme is therefore adopted, in which COMe<sub>2</sub> is its own O carrier.  $\text{COMe}_2 + \text{COMe}_2 \xrightarrow{\text{O}} \text{(II)} \rightarrow \text{MeCHO} + \text{CH}_2\text{O} + \text{COMe}_2$ ;  $\text{MeCHO}^* + \text{(II)} \rightarrow \text{AcOH} + \text{COMe}_2$ ;  $\text{CH}_2\text{O}^* + \text{(II)} \rightarrow \text{HCO}_2\text{H} + \text{COMe}_2$ . In the initial stages of the change the amounts of (I) formed in unit time are approx. const. but diminish with increasing period of irradiation. In ultra-violet light filtered through glass the formation of (I) is one fourth as fast as in unfiltered light.

H. W.

Condensation of acetone with formaldehyde. L. A. GERMANN (Compt. rend., 1936, 203, 586—587).—CH<sub>2</sub>O (1 mol.) in anhyd. EtOH containing K<sub>2</sub>CO<sub>3</sub> with COMe<sub>2</sub> (2 mols.) below 30° affords CH<sub>3</sub>Ac·CH<sub>2</sub>·OH and β-hydroxymethyl-Δ<sup>4</sup>-buten-γ-one (cf. A., 1933, 1144).

J. L. D.

Alkylacetylenes and their additive compounds. XVII. Synthesis of acetylenic ketones from acetylenic Grignard reagents. J. W. KROEGER and J. A. NIEUWLAND (J. Amer. Chem. Soc., 1936, 58, 1861—1863).—CR·C·COMe are best prepared from CR·C·MgCl (which are fairly insol. in Et<sub>2</sub>O) and Ac<sub>2</sub>O at <−25° in N<sub>2</sub>; β-keto-Δ<sup>7</sup>-octinene, b.p. 76—76.5°/15 mm., -Δ<sup>7</sup>-noninene, b.p. 89—89.5°/15 mm., and -δ-phenyl-Δ<sup>7</sup>-butinene, b.p. 101—102°/3 mm., are described. CR·C·MgBr (I) similarly gives 10—20% of ketone and considerable amounts of (CR·C)<sub>2</sub>CMe·OH; methyldi-Δ<sup>4</sup>-hexinenyl-, b.p. 123—125°/2 mm., -Δ<sup>4</sup>-heptinenyl-, b.p. 134—136°/2 mm., and -phenylacetylenyl-, m.p. 111.5—112°, -carbinols are thus prepared. (I) do not react with MeCN or NH<sub>2</sub>Ac. Little or no reaction occurs with CBr<sub>4</sub>·MgBr and dry O<sub>2</sub> at −30°.

H. B.

Chloromethylation of ketones and preparation of α-alkylvinyl ketones. J. COLOGNE (Bull. Soc. chim., 1936, [v], 3, 2116—2121).—Certain ketones are condensed with 36% CH<sub>2</sub>O in presence of HCl to β-chloroketones, transformed by NPhEt<sub>2</sub> to α-ethylenic ketones; CH<sub>2</sub>O + HCl → CH<sub>3</sub>Cl·OH (I) and (I) + COMeR → H<sub>2</sub>O + COR·CH<sub>2</sub>·CH<sub>2</sub>Cl. Thus COMeBu<sup>v</sup> gives β-chloroethyl Bu<sup>v</sup> ketone, b.p. 69—70°/9 mm. (whence 5-tert.-butylpyrazoline-2-carboxylamide, m.p. 103°), which can be kept unchanged for a few weeks but is transformed by boiling NPhEt<sub>2</sub> into COBu<sup>v</sup>·CH<sub>2</sub>·CH<sub>2</sub>, b.p. 65—66°/105 mm., which appears to polymerise rapidly. COEt<sub>2</sub> yields α-chloro-β-methylpentan-γ-one, b.p. 64°/9 mm. [semicarbazone, m.p. about 115° (decomp.)], whence β-methyl-Δ<sup>4</sup>-pentenone, b.p. 119°/731 mm. (semicarbazone, m.p. 161°). COBu<sup>a</sup><sub>2</sub> affords γ-chloromethylheptan-δ-one, b.p. 91—92°/12 mm. [semicarbazone, m.p. about 115° (decomp.)], whence γ-methylene-Δ<sup>4</sup>-

heptenone, b.p. 157—159°/742 mm. (semicarbazone, m.p. 119°).

H. W.

Oxidation of 1:3-diketones by peracetic acid. J. BOESEKEN and J. JACOBS (Rec. trav. chim., 1936, 55, 804—814).—Esters of β-keto-acids react in the enolic form with AcO<sub>2</sub>H. In the aliphatic series the reaction is COR·CHR'·COR'' + O + H<sub>2</sub>O → CHR'·OH + HR''·C<sub>2</sub>O<sub>4</sub>, in the aromatic COR·CH<sub>2</sub>·CO<sub>2</sub>Et + 3O → RCO<sub>2</sub>H + EtHC<sub>2</sub>O<sub>4</sub>. This is proved for CHAcR·CO<sub>2</sub>Et (R=H, Me, CH<sub>2</sub>Ph, OMe, and OEt), CMe<sub>2</sub>Ac·CO<sub>2</sub>Et, COR·CH<sub>2</sub>·CO<sub>2</sub>Et (R=Et, C<sub>6</sub>H<sub>11</sub>, Ph, or p-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>), COMe·CHR·COMe (R=H, Me, or CH<sub>2</sub>Ph), and CO(CH<sub>2</sub>·CO<sub>2</sub>Et)<sub>2</sub>. (COMe·CH<sub>2</sub>)<sub>2</sub> probably reacts at both enolic groupings, giving OH·CMe<CH<sub>2</sub> and thence H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> + 2EtOH.

R. S. C.

Preparation of xylulose and ribulose. P. A. LEVENE and R. S. TIPSON (J. Biol. Chem., 1936, 115, 731—747).—The products of the action of C<sub>5</sub>H<sub>5</sub>N on xylose and arabinose are best separated by way of the :CMe<sub>2</sub> derivatives, the prep. and hydrolysis of which are standardised. The ketopentose obtained from xylose is renamed d-xylulose (I). The equilibrium mixture from xylose yields d-xylose [(CMe<sub>2</sub>)<sub>2</sub> derivative, m.p. 44—45°, b.p. 78°/0.1 mm., [α]<sub>D</sub><sup>25</sup> +19.5° in COMe<sub>2</sub>], (I) [CMe<sub>2</sub> derivative, m.p. 70—71° (lit. 50—52°), b.p. 110°/0.1 mm., [α]<sub>D</sub><sup>25</sup> +1.7° in COMe<sub>2</sub>, −6.5° in H<sub>2</sub>O], and d-lyxose [CMe<sub>2</sub> derivative, m.p. 79—80°, b.p. about 110°/0.1 mm., [α]<sub>D</sub><sup>25</sup> +26° in COMe<sub>2</sub>, +19.7° (final) in H<sub>2</sub>O]. Arabinose [(CMe<sub>2</sub>)<sub>2</sub> derivative, [α]<sub>D</sub><sup>25</sup> ±0.1° in COMe<sub>2</sub>] gives d-ribose [CMe<sub>2</sub> derivative (II), an oily mixture of varying amounts of α- and β-forms, [α]<sub>D</sub><sup>25</sup>, e.g., −27.4° in COMe<sub>2</sub>; p-bromophenylhydrazone, m.p. 164—165°, [α]<sub>D</sub><sup>25</sup> +10.3° in abs. EtOH, −19.3° → +2.0° in 67.5 hr. in dry C<sub>5</sub>H<sub>5</sub>N], l-ribulose, [α]<sub>D</sub><sup>27</sup> (nearly pure) +16.6° (final) in H<sub>2</sub>O [(CMe<sub>2</sub>)<sub>2</sub> derivative, m.p. 5°, n<sub>D</sub><sup>25</sup> 1.4422, [α]<sub>D</sub><sup>27</sup> +105.5° in COMe<sub>2</sub>], and unchanged material. Some anhydro-derivative, m.p. 61°, b.p. 50—57°/0.1 mm., [α]<sub>D</sub><sup>25</sup> −64.7° in COMe<sub>2</sub>, −59.4° in H<sub>2</sub>O, of (II) is produced during the formation of (II).

R. S. C.

Determination of hexoses by fermentation. O. MEYERHOF and W. SCHULZ (Biochem. Z., 1936, 287, 206—211).—During the fermentation of pure hexoses (glucose, fructose) with living yeast the quantity of CO<sub>2</sub> produced is equiv. to only 75—80% of the sugar decomposed, but is increased by addition of substances containing N [e.g., asparagine, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, phenylalanine, protein-free extracts of tissues, yeast, urine, and serum] to the equiv. of 95% (fermentation in N<sub>2</sub>) and 100% (in CO<sub>2</sub>). These substances act by restricting the assimilation of sugar. W. McC.

Determination of glucose, galactose, and lactose in a mixture of the three sugars. M. SCOTT and E. S. WEST (Proc. Soc. Exp. Biol. Med., 1936, 34, 52—54).—The reducing vals. of solutions are determined before and after hydrolysis with acid under prescribed conditions and before and after fermentation with brewer's yeast. From the four figures so obtained the concns. of the three sugars originally present may be deduced with the help of formulæ which are given.

W. O. K.

**Determination of hydroxyl in carbohydrates by acetylation in pyridine.** J. RABATÉ (Bull. Soc. chim., 1936, [v], 3, 2112—2116).—The substance (0.1—0.2 g.) is heated for 30 min. at 100° with Delaby's reagent (B., 1935, 1118) and cooled in ice; after addition of H<sub>2</sub>O (10 c.c.) AcOH is titrated with *N*-NaOH using phenolphthalein as indicator. Results are generally accurate to within 3%, but the method fails with certain alcohols and phenols which contain CO or CHO. Among carbohydrates, the aldoses and their heterosides yield accurate results, but the process is invalid for ketoses (fructose, *d*-sorbose) or for carbohydrates containing one or more mols. of these components. H. W.

**Mechanism of carbohydrate oxidation. XVIII. Oxidation of sugars with silver oxide in the presence of potassium hydroxide.** K. G. A. BUSCH, J. W. CLARK, L. B. GENUNG, E. F. SCHROEDER, and W. L. EVANS (J. Org. Chem., 1936, 1, 1—16; cf. A., 1935, 476).—The CO<sub>2</sub>, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>, HCO<sub>2</sub>H, and OH·CH<sub>2</sub>·CO<sub>2</sub>H formed by oxidation of glucose (I), mannose (II), galactose (III), and fructose (IV), and of the intermediates, arabinose (V), erythritol, glyceraldehyde, OH·CH<sub>2</sub>·CHO (VI), and galacturonolactone by Ag<sub>2</sub>O alone and with KOH at 50° are determined. (II) is oxidised first to CH<sub>2</sub>O and (V), fructose either to (VI) (1 mol.) and erythrose (1 mol.) or 3 mols. of (VI). (I) is probably oxidised in several ways simultaneously. HCO<sub>2</sub>H is derived from CH<sub>2</sub>O, and H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and most of the CO<sub>2</sub> from CO-acids; ·CH<sub>2</sub>·OH is stable under the reaction conditions, so that the survival of OH·CH<sub>2</sub>·CO<sub>2</sub>H is explained. Reaction probably occurs by enolisation and fission at OH·C·C·OH. R. S. C.

**Oxidation of glucose in presence of insulin, glutathione, and other substances, and the probable mechanism of biological oxidations.** C. C. PALIT and N. R. DHAR (J. Indian Chem. Soc., 1936, 13, 502—508).—Glutathione (I) and insulin (II), with or without phosphate or heavy-metal salts, usually accelerate but sometimes retard the oxidation by air of aq. solutions of glucose in presence of TiO<sub>2</sub>, SiO<sub>2</sub>, Ce(OH)<sub>2</sub>, Fe(OH)<sub>2</sub>, or Mn(OH)<sub>2</sub> (cf. A., 1934, 1314). (I) and (II) presumably act as O acceptors. E. W. W.

**Structures of isopropylidene derivatives of galactose-, glucose-, and mannose-dibenzyl mercaptals.** E. PACSU (J. Amer. Chem. Soc., 1936, 58, 2076).—Re-investigation of the compounds is being carried out (cf. Munro and Percival, this vol., 826) in view of previous work (A., 1932, 254). The supposed 2:3-isopropylidene-galactose dibenzyl mercaptal, m.p. 102—103° (A., 1930, 197), is a mixture of (probably) the 4:6-, m.p. 101.5°, [α]<sub>D</sub><sup>20</sup> +30.5° in CHCl<sub>3</sub>, and 5:6-, m.p. 112.5°, [α]<sub>D</sub><sup>20</sup> +17.4° in CHCl<sub>3</sub>, derivatives; neither reacts with CPh<sub>3</sub>Cl. H. B.

**Syntheses with 5:6-anhydroisopropylidene-glucose. IV. Derivatives of glucosyl-6-phenylamine (6-anilinochinovose).** H. OHLE, H. FRIEDBERG, and G. HAESLER (Ber., 1936, 69, [B], 2311—2324; cf. this vol., 1094).—With amines of the hexose series with NH<sub>2</sub> at C<sub>6</sub>, the relationship to the methylpentoses of similar configuration can be simply

expressed, e.g., glucosyl-6-amine=6-amino-6-deoxy-glucose=6-aminoisorhamnose. The use of prefixes such as *iso*- and *epi*- is regarded as undesirable, and it is considered advisable to choose for each sugar a short trivial name related, if possible, to its origin. The use of chinovose for *d*-isorhamnose is therefore advocated (cf. Freudenberg *et al.*, A., 1929, 427). Addition of NH<sub>2</sub>Ph to 5:6-anhydroisopropylidene-glucose (I) gives 6-anilino-1:2-isopropylidene-*d*-chinofuranose (II), b.p. 220°/15 mm. (N·SO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>Me derivative (III), m.p. 195.5°, [α]<sub>D</sub><sup>20</sup> −10.54° in CHCl<sub>3</sub>, −7.16° in MeOH). (I) and NH<sub>2</sub>Ph (1:2 mols.) at 80—100° yield non-cryst. *di*(isopropylidene-6-*d*-glucosyl)aniline, identified as the *tetra-acetate*, m.p. 194°, [α]<sub>D</sub><sup>20</sup> +19.4° in CHCl<sub>3</sub>. From α- or β-C<sub>10</sub>H<sub>7</sub>·NH<sub>2</sub>, tetrahydroquinoline, *ac*- or *ar*-tetrahydronaphthylamine only isopropylidene-6-*d*-glucosyl-*ar*-tetrahydro-β-naphthylamine, m.p. 187°, [α]<sub>D</sub><sup>20</sup> −1.6° in CHCl<sub>3</sub>, could be obtained cryst. (III) is also obtained directly from (I) and *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub>·NHPH at about 150° in presence of a little C<sub>5</sub>H<sub>5</sub>N, and the method is extended to the prep. of the following: *N*-*p*-toluenesulphonyl derivatives of isopropylidene-6-*d*-glucosyl-*p*-bromoaniline (IV), m.p. 224°, [α]<sub>D</sub><sup>20</sup> +12.09° in CHCl<sub>3</sub> (*p*-toluenesulphon-*p*'-bromoanilide, m.p. 147.5°), *p*-anisidine, m.p. 197°, [α]<sub>D</sub><sup>20</sup> +6.4° in CHCl<sub>3</sub>, 2'-naphthylamine, m.p. 172°, [α]<sub>D</sub><sup>20</sup> +16.4° in CHCl<sub>3</sub>, and to the *N*-α-, m.p. 223—225°, [α]<sub>D</sub><sup>20</sup> −14.2° in CHCl<sub>3</sub>, and *N*-β-, m.p. 228—230°, [α]<sub>D</sub><sup>20</sup> ±0° in CHCl<sub>3</sub>, *naphthalenesulphonyl* compounds of isopropylidene-6-*d*-glucosylaniline. If the amine component is not aromatic the change does not take place, or occurs so slowly that it is almost completely repressed by the autocondensation of (I). This appears also true of the amides of aliphatic and aromatic carboxylic acids, e.g., NH<sub>2</sub>Ac, NHAc, NHPHAc, NH<sub>2</sub>Bz, NHBz<sub>2</sub>, and NHPHBz, but *o*-C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>)NH is exceptional. Mild treatment with alkali does not cause hydrolysis of the derivatives, whereas more drastic action involves removal of *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub>·NHPH, hydrolysed to *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>3</sub>H and NH<sub>2</sub>Ph, and resinification of the sugar. (III) is readily converted by 50% AcOH into *N*-*p*-toluenesulphonyl-6-anilino-β-*d*-chinovose, m.p. 95—110°, or +1.5H<sub>2</sub>O, m.p. 87—89°, [α]<sub>D</sub><sup>20</sup> −0.63° to +64.2° in COMe<sub>2</sub>, [α]<sub>D</sub><sup>20</sup> +57.7° (const.) in C<sub>5</sub>H<sub>5</sub>N, converted by Ac<sub>2</sub>O in C<sub>5</sub>H<sub>5</sub>N into *N*-*p*-toluenesulphonyl-6-anilino-β-*d*-chinopyranose 1:2:3:4-tetraacetate (V), m.p. 190°, [α]<sub>D</sub><sup>20</sup> +19.87° in CHCl<sub>3</sub>, mixed with the α-variety, [α]<sub>D</sub><sup>20</sup> +64.3° in CHCl<sub>3</sub>. The isomeric *N*-*p*-toluenesulphonyl-6-anilino-α-*d*-chinofuranose 1:2:3:5-tetraacetate (VII), m.p. 139—140°, [α]<sub>D</sub><sup>20</sup> +74.3° in CHCl<sub>3</sub>, is obtained by hydrolysis of *N*-*p*-toluenesulphonylisopropylidene-6-anilino-chinofuranose 3:5-diacetate with 50% AcOH and acetylation of the product. (V) reacts abnormally

with HBr·AcOH, giving (C<sub>6</sub>H<sub>4</sub>Me)<sub>2</sub>S and 6-2':4'-dibromoanilinochinovosyl 1-bromide 2:3:4-*tri*-

acetate (VII), m.p. 144—145°,  $[\alpha]_D^{20} +135.6^\circ$  in  $\text{CHCl}_3$ , accompanied by 6-2':4'-dibromoanilino-d-chinovose hydrobromide, the yields of which are improved by pre-addition of Br. Under similar conditions, (VI) does not yield a cryst. material. The location of Br at C<sub>11</sub> in (VII) is established by the conversion of (VII) by  $\text{Ag}_2\text{O}$  and boiling abs. MeOH into 6-2':4'-dibromoanilino- $\beta$ -methyl-d-chinopyranoside 2:3:4-triacetate (VIII), m.p. 139—140°,  $[\alpha]_D^{20} +3.83^\circ$  in  $\text{CHCl}_3$ , transformed by boiling  $\text{Ac}_2\text{O}$ , but not by acetylation in  $\text{C}_5\text{H}_5\text{N}$ , into N-acetyl-6-2':4'-dibromoanilino- $\beta$ -methyl-d-chinopyranoside 2:3:4-triacetate, m.p. 158°,  $[\alpha]_D^{20} +34.0^\circ$  in  $\text{CHCl}_3$ , hydrolysed to the non-cryst. N-acetyl-6-2':4'-dibromoanilino- $\beta$ -methyl-d-chinopyranoside. Hydrolysis of (VIII) by NaOMe gives 6-2':4'-dibromoanilino- $\beta$ -methyl-d-chinopyranoside, m.p. 172°,  $[\alpha]_D^{20} -4.82^\circ$  in  $\text{C}_5\text{H}_5\text{N}$ . Further (VII) and  $\text{AgOAc}$  in AcOH afford 6-2':4'-dibromoanilino- $\beta$ -d-chinopyranose 1:2:3:4-tetra-acetate, m.p. 168°,  $[\alpha]_D^{20} +18.9^\circ$  in  $\text{CHCl}_3$ , from which the cryst. sugar could not be obtained with NaOMe or  $\text{NH}_3\text{-MeOH}$ ; it is transformed by boiling  $\text{Ac}_2\text{O}$  into N-acetyl-6-2':4'-dibromoanilino- $\beta$ -d-chinopyranose 1:2:3:4-tetra-acetate, m.p. 148°,  $[\alpha]_D^{20} +45.0^\circ$  in  $\text{CHCl}_3$ . The position of the second Br in (VII) follows from the conversion of (IV) into (VII) by  $\text{HBr-AcOH}$ , reaction occurring slowly and with poor yield. For the elucidation of the position of the third Br direct synthesis fails owing to lack of additive capacity of 2:4- $\text{C}_6\text{H}_3\text{Br}_2\text{-NH}_2$ . Reduction of (VII) with Zn dust and AcOH gives good yields of 6-2':4'-dibromoanilinochinoxal 3:4-diacetate (IX), m.p. 86—87°,  $[\alpha]_D^{20} -2.3^\circ$  in  $\text{CHCl}_3$ , readily hydrolysed (Zemplén) to 6-2':4'-dibromoanilino-d-chinoxal, m.p. about 142°,  $[\alpha]_D^{20} +15.50^\circ$  in MeOH, which adds Br, is catalytically hydrogenated ( $\text{Pd-BaSO}_4$ ), is degraded by  $\text{O}_3$ , and resinified by mineral acids. Oxidation by  $\text{KMnO}_4$  in  $\text{COMe}_2$  destroys completely the sugar component but yields 2:4- $\text{C}_6\text{H}_3\text{Br}_2\text{-NH}_2$  and 2:4-dibromoxanilic acid. (V) is transformed by  $\text{TiCl}_4$  in  $\text{CHCl}_3$  into N-p-toluenesulphonyl-6-anilinochinopyranosyl 1-chloride 2:3:4-triacetate, m.p. 84—95°,  $[\alpha]_D^{20} +114.9^\circ$  in  $\text{CHCl}_3$ ; the yield is poor and the change is accompanied by formation of p- $\text{C}_6\text{H}_4\text{Me-SO}_2\text{Cl}$ . It is converted by  $\text{Ag}_2\text{O}$  in boiling MeOH into N-p-toluenesulphonyl-6-anilino- $\beta$ -methyl-d-chinopyranoside 2:3:4-triacetate, m.p. 147°,  $[\alpha]_D^{20} +5.0^\circ$  in  $\text{CHCl}_3$ , hydrolysed (Zemplén) to N-p-toluenesulphonyl-6-anilino- $\beta$ -d-methylchinopyranoside, m.p. 128°,  $[\alpha]_D^{20} +2.62^\circ$ . It is unusually stable towards alkalis so that p- $\text{C}_6\text{H}_4\text{Me-SO}_2$  cannot be removed in this manner. Under similar conditions (VI) gives cryst. products differing from those described above in amount too small for further investigation. H. W.

" $\beta$ "-d-Glucose 2:3:4:6-tetra-acetate. S. B. HENDRICKS, O. R. WULF, and U. LIDDEL (J. Amer. Chem. Soc., 1936, 58, 1997—1999).— $\beta$ -d-Glucose 2:3:4:6-tetra-acetate (I), prepared by Fischer and Delbrück's method (A., 1909, i, 633), is obtained in two forms, (Ia), m.p. 122—125° (from EtOAc),  $[\alpha]_D^{20} +15^\circ$  in EtOH, and (Ib), m.p. 138—140° [from Et<sub>2</sub>O (4 times) and then  $\text{C}_6\text{H}_6$  (twice)],  $[\alpha]_D^{20}$  (in EtOH)  $-4.2^\circ \rightarrow +75^\circ$  (10 days), (in  $\text{CHCl}_3$ )  $+18.8^\circ \rightarrow +78^\circ$  (10 days) (cf. Georg, A., 1932, 835). (Ib) is converted

into (Ia) when kept (2 years) or heated in  $\text{CCl}_4$  or  $\text{C}_6\text{H}_6$  for several days; subsequent recrystallisation of the (Ia) from Et<sub>2</sub>O affords (Ib). Microscopical examination and X-ray powder diffraction patterns show that (Ia) and (Ib) are isomorphous. The above phenomenon is not shown by (I), m.p. 125—131°, prepared by Weizmann and Haskelberg's method (A., 1935, 1108). Infra-red absorption curves, showing characteristic OH-absorption, are given for (Ia), (Ib),  $\beta$ -d-galactose 2:3:4:6-tetra-acetate, and  $\alpha$ -d-xylose 2:3:4-triacetate. H. B.

3:6-Dimethylglucose: methods of synthesis. D. J. BELL (J.C.S., 1936, 1553—1554).—3:5-isopropylidene-glucose 6-acetate with  $\text{N}_2\text{O}_5$  in  $\text{CHCl}_3$  gives isopropylidene-glucose 3:5-dinitrate 6-acetate, m.p. 81.5—82.5°,  $[\alpha]_D^{20} -22.7^\circ$  in  $\text{CHCl}_3$ , which with  $\text{NHMe}_2$  in EtOH yields isopropylidene-glucose 5-nitrate, m.p. 86—87° and 106°,  $[\alpha]_D^{20} -0.4^\circ$  in EtOH, and with MeI and  $\text{Ag}_2\text{O}$  gives 3:6-dimethylisopropylidene-glucose, a syrup,  $[\alpha]_D^{20} -45.9^\circ$  in  $\text{CHCl}_3$  (also obtained from 3-methylisopropylidene-glucose by successive treatment with p- $\text{C}_6\text{H}_4\text{Me-SO}_2\text{Cl}$  and NaOMe), hydrolysed (HCl) to 3:6-dimethylglucose. F. R. G.

Photochemical peroxide formation. V. Oxidation of fructose by molecular oxygen in ultra-violet light. Photochemical formation of perfructose. R. CANTIENI (Ber., 1936, 69, [B], 2286—2288).—Fructose is converted by  $\text{O}_2$  into a peroxide in ultra-violet light of long and short  $\lambda$ . Since photolysis of it affects almost exclusively the CO group it is assumed that photo-oxidation occurs thus:

Ditriphenylmethylfructose. B. HELFERICH [with G. PYL, H. PAUKERT, and E. GUNTHER] (J. pr. Chem., 1936, [ii], 147, 60—63).—Fructose and  $\text{CPh}_3\text{Cl}$  (2 mol.) in abs.  $\text{C}_5\text{H}_5\text{N}$  at room temp. give 1:6-ditriphenylmethyl-d-fructose, anhyd., amorphous, and  $+2\text{C}_5\text{H}_5\text{N}$ , m.p. 96—97°,  $[\alpha]_D^{20} +17.5^\circ$  in  $\text{CHCl}_3$ , which gives an oxime, m.p. about 186° (decomp.),  $[\alpha]_D^{20} -18^\circ$  in  $\text{C}_6\text{H}_5\text{N}$ , also obtained from fructose oxime and  $\text{CPh}_3\text{Cl}$  (2 mol.). R. S. C.

Convallamarin. W. VOSS and G. VOGT (Ber., 1936, 69, [B], 2333—2342).—Technical convallamarin is purified successively by distribution between BuOH and  $\text{H}_2\text{O}$ , fractional adsorption by active C, and fractional pptn. by Et<sub>2</sub>O from MeOH, thereby giving an amorphous product for which the name convallamarin (I) is retained and which could not be separated into portions with differing physical consts. It retains an almost negligible cardiac activity and has a very low foam no. attributed to the presence of traces of convallatoxin and convallarin, respectively; it is considered to be about 99.5% pure. It does not give the Legal test and does not contain a lactone group or give a compound with cholesterol. It has  $[\alpha]_D^{20} -66.5^\circ$  in Et<sub>2</sub>O. Elementary analyses indicates the formula  $\text{C}_{41}\text{H}_{70}\text{O}_{19}\cdot 3\text{H}_2\text{O}$ , and the presence of one double

linking is established by hydrogenation. The sugar components are glucose (1 mol.) and *l*-rhamnose (2 mols.). Hydrolysis with aq. acids proceeds satisfactorily only in very dil. solution, and the use of 2% HCl-MeOH at 35° is preferable, whereby the sugars are quantitatively transformed into their methylglucosides and the aglucone is protected. The very ready alcoholysis of glucosides and the consequent danger of the use of possibly acidic EtOH in their extraction is stressed. *Convallamaretin*, m.p. 248.5—250.5° (decomp.),  $[\alpha]_D^{20}$  -86.0° in CHCl<sub>3</sub>, contains one double linking, 2 OH (Zerevitinov determination at higher temp.), but not CO. Elementary analyses agree best with C<sub>20</sub>H<sub>40</sub>O<sub>5</sub>, and harmonise with the hydrolysis, C<sub>44</sub>H<sub>70</sub>O<sub>19</sub> + 3H<sub>2</sub>O → C<sub>20</sub>H<sub>40</sub>O<sub>5</sub> + C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> + 2C<sub>6</sub>H<sub>12</sub>O<sub>5</sub>. The presence of only two oxide rings is considered probable, whilst the remaining 3 O are present as 3 OH only two of which are affected by MgMeI. H. W.

**Constituents of seeds of *Digitalis lanata* (Ehrh.).**—See this vol., 1571.

**Kinetics of the sulphite [cellulose] process.**—See this vol., 1470.

**[Preparation of] primary amines by reduction of oximes by aluminium amalgam.** C. L. TSENG and C. CHANG (Sci. Rep. Nat. Univ. Peking, 1936, 1, No. 3, 19—33).—The oximes of the following compounds with Al-Hg in 96% or aq. EtOH give the stated yields of primary base with, in some cases, small amounts of *sec.* amine: COMe<sub>2</sub> 17.3, Pr<sup>n</sup>CHO 39.9, *n*-C<sub>6</sub>H<sub>13</sub>CHO 48, COMe·C<sub>6</sub>H<sub>13</sub>-*n* 1.6, cyclohexanone 60.1, PhCHO 87.7, camphor 85, and furfuraldehyde 36.3%. Phenylhydrazones give similarly good yields of NH<sub>2</sub>Ph and primary base, but the method is of val. only when the NH<sub>2</sub>Ph and other base are readily separated. PhCN resists reduction by Al-Hg. Al foil of 0.1 mm. thickness or Al turnings give best results. The prep. of the Al-Hg, oximes, and phenylhydrazones used is described.

R. S. C.

**Reineckates of organic bases.** H. CARLSOHN and F. RATHMANN (J. pr. Chem., 1936, [ii], 147, 29—37).—Many reineckates are more sol. in H<sub>2</sub>O-COMe<sub>2</sub> or -EtOAc than in either solvent alone. In general these salts are more sol. in H<sub>2</sub>O, the less sol. they are in COMe<sub>2</sub>. In EtOH the order of solubility is usually primary > *sec.* > *tert.* > quaternary aliphatic salts. The NPr<sub>4</sub> salt is least sol. in EtOH containing 2.2% of H<sub>2</sub>O.

R. S. C.

**Carboxymethoxylamine [aminooxyacetic acid].** E. BOREK and H. T. CLARKE (J. Amer. Chem. Soc., 1936, 58, 2020—2021).—Crude CMe<sub>2</sub>·N·O·CH<sub>2</sub>·CO<sub>2</sub>Et (from dry CMe<sub>2</sub>·N·ONa and CH<sub>2</sub>Cl·CO<sub>2</sub>Et) is hydrolysed (11.4% NaOH at 100°) to CMe<sub>2</sub>·N·O·CH<sub>2</sub>·CO<sub>2</sub>H, m.p. 76—76.5° [also prepared (cf. Hantzsch and Wild, A., 1896, i, 285) in smaller yield from CMe<sub>2</sub>·N·OH and CH<sub>2</sub>Cl·CO<sub>2</sub>Na in aq. NaOH], further hydrolysed (boiling 6*N*-HCl) to NH<sub>2</sub>·O·CH<sub>2</sub>·CO<sub>2</sub>H (I) (*hemihydrochloride*, m.p. 151°). *Acetophenoneoxime*, m.p. 97—97.5°, benzaldoxime, m.p. 96° (lit. 98°), and pyruvic acid oxime, m.p. 129° (lit. 130—132°), *O*-carboxymethyl ethers are prepared from (I) and the requisite CO-compound.

H. B.

**Action of amines on esters of the trichloro-nitrohydroxy-paraffins.** F. D. CHATTAWAY, J. G. N. DREWITT, and G. D. PARKES (J.C.S., 1936, 1530—1532; cf. this vol., 595, 1362).—CRCl<sub>2</sub>·CH(CH<sub>2</sub>·NO<sub>2</sub>)·O·COR' with NH<sub>2</sub>R'' gives CRCl<sub>2</sub>·CH(CH<sub>2</sub>·NO<sub>2</sub>)·NHR''. With NH<sub>3</sub> or the appropriate amine, CCl<sub>3</sub>·CH(CH<sub>2</sub>·NO<sub>2</sub>)·OAc or its *p*-nitrobenzoate, m.p. 87°, yields  $\gamma\gamma\gamma$ -trichloro- $\alpha$ -nitro- $\beta$ -methyl-, b.p. 96°/3 mm. (*hydrochloride*, decomp. about 185°; *phenylcarbamyl* derivative, m.p. 130°), - $\beta$ -ethyl-, b.p. 106°/2 mm. (*hydrochloride*, m.p. 146°; *phenylcarbamyl* derivative, m.p. 121°), and  $\beta$ -allyl-amino-propane, b.p. 106°/2 mm. [*hydrochloride*, m.p. 141° (decomp.); *phenylcarbamyl* derivative, m.p. 124°]; CHMeCl·CCl<sub>2</sub>·CH(CH<sub>2</sub>·NO<sub>2</sub>)·OAc yields  $\gamma\gamma\delta$ -trichloro- $\alpha$ -nitro- $\beta$ -methyl-, b.p. 110°/2 mm. [*hydrochloride*, m.p. 172°; *phenylcarbamyl* derivative, m.p. 186° (decomp.)], - $\beta$ -ethyl-, b.p. 115°/0.7 mm. (*hydrochloride*, m.p. 120°; *phenylcarbamyl* derivative, m.p. 140°), and - $\beta$ -allyl-amino-*n*-pentane, b.p. 116°/0.5 mm. (decomp.) [*hydrochloride*, m.p. 140° (decomp.)]; CCl<sub>3</sub>·CH(CHMe·NO<sub>2</sub>)·OAc yields  $\delta\delta\delta$ -trichloro- $\beta$ -nitro- $\gamma$ -methylamino-, b.p. 94°/0.5 mm. (*hydrochloride*, m.p. 194°), - $\gamma$ -*p*-toluidino-, m.p. 99—100°, and - $\gamma$ -phenylhydrazino-*n*-butane, m.p. 108—109°; CHMeCl·CCl<sub>2</sub>·CH(CHMe·NO<sub>2</sub>)·OAc yields  $\delta\delta\epsilon$ -trichloro- $\beta$ -nitro- $\gamma$ -methylamino-, b.p. 109°/0.3 mm. (*hydrochloride*, m.p. about 200°), and - $\gamma$ -*p*-toluidino-*n*-hexane, m.p. 82°; CCl<sub>3</sub>·CH(CHPh·NO<sub>2</sub>)·OAc yields  $\gamma\gamma\gamma$ -trichloro- $\alpha$ -nitro- $\beta$ -*p*-toluidino-, m.p. 121—122°, and - $\beta$ -phenylhydrazino- $\alpha$ -phenylpropane, m.p. 155° (decomp.). F. R. G.

**Polyamines. II. Preparation of  $\beta\beta'$ -diamino-diethylamine and NN'-bis-( $\beta$ -aminodiethyl)ethylenediamine.** D. H. PEACOCK (J.C.S., 1936, 1518—1520; cf. A., 1934, 1207).—*p*-Toluenesulphon- $\beta$ -chloroethylamide with (CH<sub>2</sub>·NH<sub>2</sub>)<sub>2</sub> in EtOH gives N-( $\beta$ -*p*-toluenesulphonamidoethyl)ethylenediamine dihydrochloride, m.p. 182° {CuSO<sub>4</sub> complex, [(C<sub>11</sub>H<sub>19</sub>O<sub>2</sub>N<sub>3</sub>S)<sub>2</sub>Cu(H<sub>2</sub>O)<sub>2</sub>]SO<sub>4</sub>; NiSO<sub>4</sub> complex}, and the dihydrochloride, m.p. 246°, of NN'-bis-( $\beta$ -*p*-toluenesulphonamidoethyl)ethylenediamine, m.p. 160°, hydrolysed (H<sub>2</sub>SO<sub>4</sub>) to NN'-bis-( $\beta$ -aminoethyl)ethylenediamine {tetrahydrochloride, m.p. 266—270°; CuSO<sub>4</sub> and KPtCl<sub>6</sub> [Pt(C<sub>6</sub>H<sub>14</sub>N<sub>4</sub>)]PtCl<sub>4</sub> (?), complexes}. NH(CH<sub>2</sub>·CH<sub>2</sub>Br)<sub>2</sub>·HBr and NH<sub>3</sub> in EtOH give NH(CH<sub>2</sub>·CH<sub>2</sub>Br)<sub>2</sub> and piperazine, identified as their *p*-C<sub>6</sub>H<sub>4</sub>Me·SO<sub>2</sub> derivatives. F. R. G.

**Aliphatic polyamines. III.** J. VAN ALPHEN (Rec. trav. chim., 1936, 55, 835—840; cf. this vol., 1274).—Br·[CH<sub>2</sub>]<sub>3</sub>·Br and NH<sub>2</sub>·[CH<sub>2</sub>]<sub>2</sub>·NH<sub>2</sub>·H<sub>2</sub>O in abs. EtOH, first alone and then with KOH, give NN'-di- $\beta'$ -aminoethylpropylene- $\alpha\gamma$ -diamine (I), b.p. 185—186°/35 mm., 286—287°/760 mm. (*tetra*-, m.p. about 223°, and *tri*-picrate, m.p. 171°; *tetraoxalate*, m.p. 237°; *tetraphenyl-carbamide*, m.p. 145—155°, and -thiocarbamide, m.p. 179°, and *Bz*<sub>4</sub> derivative, m.p. 172°; gives a reddish-violet colour with aq. Cu salts), and a fraction, b.p. 274—276°/35 mm. (I) and PhCHO give a gum, which with Na-EtOH affords NN'-di- $\beta'$ -benzylaminoethylpropylene- $\alpha\gamma$ -diamine (II), m.p. 44° [*tetra*-hydrochloride, m.p. 270—290° (decomp.), -picrate, m.p. 201°, and -oxalate, m.p. 247°; (NO)<sub>4</sub>-, m.p. 99°, and *tetraphenylthio*-

carbamide derivative, m.p. 130—135°]. (I) and CS<sub>2</sub> in EtOH give  $\alpha$ -di-2-thiotetrahydroglyoxalinypropene, m.p. 156°. (II) with PhCHO or *p*-OMe-C<sub>6</sub>H<sub>4</sub>·CHO gives  $\alpha$ -di-2-phenyl-, m.p. 123°, and -*p*-anisyl-, m.p. 110°, -3-benzyltetrahydro-1-glyoxalinypropene, m.p. 110°. R. S. C.

**Alcoholysis in the reaction between triethanolamine and bivalent metal salts.** IV. F. GARELLI and A. TETTAMANZI (Atti R. Accad. Sci. Torino [Cl. Sci. fis. mat.], 1934, 69, I, 89—96; Chem. Zentr., 1936, i, 535).—In presence of H<sub>2</sub>O, N(CH<sub>2</sub>·CH<sub>2</sub>·OH)<sub>3</sub> reacts as the hydrate, NH(OH)(C<sub>2</sub>H<sub>4</sub>·OH)<sub>3</sub>. Earlier results are summarised. H. N. R.

**Production of methyl esters of difficultly esterified acids.** V. PRELOG and M. PIANTANIDA (Z. physiol. Chem., 1936, 244, 56—58).—The acids, in MeOH, are converted into NMe<sub>4</sub> salts by titration with NMe<sub>4</sub>·OH in MeOH avoiding excess, MeOH and any residual NMe<sub>4</sub>·OH are removed by heating, and the salts are destructively distilled at 200—300° preferably in a vac., thus giving high yields of Me ester. Me esters of NH<sub>2</sub>-acids may be prepared thus. W. McC.

**Preparation of  $\alpha$ -amino-acids from alkylcyanoacetic acids.** A. DARAPSKY [with H. DECKER, E. STEUERNAGEL, and O. SCHIEDRUM] (J. pr. Chem., 1936, [iii], 146, 250—267; cf. A., 1916, i, 127).—CN·CHPr<sup>a</sup>·CO<sub>2</sub>Et and N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O at room temp. give the non-cryst. *n*-propylcyanoacethydrazide CN·CHPr<sup>a</sup>·CO·NH·NH<sub>2</sub> (CMe<sub>2</sub> derivative, m.p. 98—100°), converted by NaNO<sub>2</sub> and HCl into the oily *n*-propylcyanoacetazide which with boiling EtOH·Et<sub>2</sub>O affords *Et*  $\alpha$ -cyano-*n*-butylcarbamate, transformed by boiling conc. HCl into  $\alpha$ -amino-*n*-valeric acid, m.p. 291° (corr.; decomp.) in a sealed capillary [hydrochloride; Cu salt; Bz, m.p. 152°, and SO<sub>2</sub>Ph, m.p. 150—152° (corr.), derivatives]. Et isobutylcyanoacetate is converted by N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O in boiling EtOH into diisobutylcyanoacethydrazide, (·NH·CO·CHBu<sup>β</sup>·CN)<sub>2</sub>, m.p. 198°, which does not condense with PhCHO. At room temp. in the absence of solvents the reactants yield the monohydrazidinedehydrazide, NH<sub>2</sub>·NH·CO·CHBu<sup>β</sup>·C(NH)·NH·NH<sub>2</sub>, m.p. 101°, which condenses with PhCHO, whereas in presence of EtOH at room temp. they yield isobutylcyanoacethydrazide (CMe<sub>2</sub>, m.p. 81—82°, ·CHPh, m.p. 95°, and *o*-hydroxybenzylidene, m.p. 115°, derivatives). Non-cryst. isobutylcyanoacetazide is transformed by NH<sub>2</sub>Ph in Et<sub>2</sub>O into isobutylcyanoacetanilide, m.p. 192°, and by boiling EtOH into *Et*  $\alpha$ -cyanoisomethylcarbamate, which with boiling conc. HCl affords  $\alpha$ -aminoisohexic acid, m.p. 293° in a sealed capillary (Cu salt; ·SO<sub>2</sub>Ph derivative, m.p. 143°). Et isoamylcyanoacetate yields isoamylcyanoacethydrazide, m.p. 100° (unstable, hygroscopic hydrochloride, m.p. 107°, ·CMe<sub>2</sub>, m.p. 81°, and ·CHPh, m.p. 85°, derivatives), converted by I in cold abs. EtOH into diisoamylcyanoacethydrazide, C<sub>16</sub>H<sub>26</sub>O<sub>2</sub>N<sub>4</sub>, m.p. 180° (decomp.). Non-cryst. isoamylcyanoacetazide yields isoamylcyanoacetanilide, m.p. 108°, and non-cryst. *Et*  $\alpha$ -cyanoisohexylcarbamate, CH<sub>2</sub>Bu<sup>β</sup>·CH(CN)·NH·CO<sub>2</sub>Et, hydrolysed by boiling 20% HCl to  $\alpha$ -amino- $\delta$ -methyl-*n*-hexic acid, m.p. 266° (decomp.) [hydrochloride, Cu salt, *Et* ester (I), b.p. 59°/19 mm., and its hydro-

chloride, m.p. 86°]. When kept in a sealed tube (I) slowly passes into 2:5-diketo-3:6-diisoamylpiperazine, m.p. 281° (decomp.). H. W.

**Methylation of glycine.** F. CHALLENGER (Chem. and Ind., 1936, 900—901).—The suggestion (A., 1935, 1027) that glycine (I), through its deamination products CHO·CO<sub>2</sub>H and CH<sub>2</sub>O, is the active agent in biological methylation (often a detoxication process) is supported by a review of relevant lit. The assumption of self-methylation explains the formation of sarcosine and betaine. The methylating action of (I) itself is exemplified by the conversion of nicotinic acid into trigonelline and nicotinuric acid. J. W. B.

**Specificity of papain peptidase.**—See this vol., 1557.

**Spatial configuration of [natural]  $\alpha$ -amino- $\beta$ -hydroxy-*n*-butyric acid.** C. E. MEYER and W. C. ROSE (J. Biol. Chem., 1936, 115, 721—729).—The  $\alpha$ -amino- $\beta$ -hydroxy-*n*-butyric acid isolated from proteins is shown to be (I); it is named *d*(or *D*)(-)-threonine. The dextro- (II) and lævo-rotatory (III) threodihydroxybutyric acids are the *l*(+)- and *d*(-)-compounds, respectively. (I) and HI-P at 150—155° give partly racemised *d*- $\alpha$ -amino-*n*-butyric acid with  $[\alpha]_D^{25} +4.18^\circ$  in H<sub>2</sub>O. With chloramine-T it affords *l*-lactaldehyde (not isolated), oxidised to *l*-lactic acid. With Ba(NO<sub>3</sub>)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub> at 0° (I) gives (III) (phenylhydrazide, m.p. 103.5—104°,  $[\alpha]_D^{25} -16.25^\circ$  in H<sub>2</sub>O). The phenylhydrazides of (II) and the *dl*-form have m.p. 102—104° and 129.5—131°, respectively. R. S. C.

**Polypeptidases of blood-serum and -plasma.**—See this vol., 1556.

**Hydrazino-acids.** IV. A. DARAPSKY [with J. GERMSCHIED, C. KREUTER, E. ENGELMANN, W. ENGELS, and W. TRINIUS] (J. pr. Chem., 1936, [ii], 146, 219—249; cf. A., 1918, i, 506, 553; 1919, i, 601).—CHPr<sup>β</sup>Br·CO<sub>2</sub>H and N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O in boiling EtOH give  $\alpha$ -hydrazinoisovaleric acid, m.p. 230—235° [hydrochloride, m.p. 135.5°; *o*-hydroxybenzylidene, m.p. 124°, and cinnamylidene, m.p. 137—139°, derivatives; unstable *Me* ester and its hydrochloride (I), m.p. 112°; unstable *Et* ester and its hydrochloride (II), m.p. 104°], which is not converted by conc. aq. NH<sub>3</sub> into its NH<sub>4</sub> salt. (I) is transformed by aq. KCNO into *Me*  $\alpha$ -carbamyldiazinoisovalerate, NH<sub>2</sub>·CO·NH·NH·CHPr<sup>β</sup>·CO<sub>2</sub>Me, m.p. 126.5°, which does not condense with PhCHO or *o*-OH·C<sub>6</sub>H<sub>4</sub>·CHO and does not appear to yield a hydrochloride. *Et*  $\alpha$ -carbamyldiazinoisovalerate, from (II), has m.p. 130°. (I) is converted by NaNO<sub>2</sub> in conc. aq. solution into *Me*  $\alpha$ -nitrosohydrazinoisovalerate (III), NH<sub>2</sub>·N(NO)·CHPr<sup>β</sup>·CO<sub>2</sub>Me, m.p. 35.5°, which readily decomposes when preserved, probably accompanied by *Me*  $\alpha$ -hydroxyisovalerate. *Et*  $\alpha$ -nitrosohydrazinoisovalerate is an unstable oil. (III) passes at 115—120° into N<sub>2</sub>O and *Me*  $\alpha$ -aminoisovalerate, b.p. 56°/14 mm. (hydrochloride, m.p. 116.5°; picrate, m.p. 145.5°), which decomposes when kept, probably giving diketodisopropylpiperazine. When distilled with steam in presence of 10% H<sub>2</sub>SO<sub>4</sub> (III) affords

*Me*  $\alpha$ -azidoisovalerate, b.p. 50°/15 mm., hydrolysed by aq. NaOH at room temp. to non-cryst.  $\alpha$ -azidoisovaleric acid ( $\text{NH}_4$  and Ag salts). The following substances are obtained by an analogous series of reactions:  $\alpha$ -hydrazino-*n*-hexoic acid, m.p. 199—201° (very hygroscopic hydrochloride;  $\text{:CHPh}$ , m.p. 102—103°, *o*-hydroxybenzylidene, m.p. 123—124°, and  $\text{Bz}_2$ , m.p. 157—158°, derivatives; *Et* ester hydrochloride, m.p. 75°; very hygroscopic *Me* ester hydrochloride); *Et*  $\alpha$ -carbamyldiazino-*n*-hexoate, m.p. 102—103°; *Et*  $\alpha$ -nitrosohydrazino-*n*-hexoate; *Et*  $\alpha$ -amino-*n*-hexoate, b.p. 91—93°/11—12 mm., whence the corresponding acid, m.p. 299—303° in a sealed capillary, and its Cu salt; *Et*  $\alpha$ -azido-*n*-hexoate, b.p. 93—95°/13—14 mm., also obtained from  $\text{CHBu}^{\text{a}}\text{Br}\cdot\text{CO}_2\text{Et}$  and  $\text{NaN}_3$ , whence non-cryst.  $\alpha$ -azido-*n*-hexoic acid (non-cryst.  $\text{NH}_4$  and Ag salts);  $\alpha$ -hydrazinoisohexoic acid  $\text{CH}_2\text{Pr}^{\text{b}}\cdot\text{CH}(\text{NH}\cdot\text{NH}_2)\cdot\text{CO}_2\text{H}$ , m.p. 228° [hydrochloride, m.p. 170—177° (decomp.);  $\text{:CHPh}$ , m.p. 115·5°, *o*-hydroxybenzylidene, m.p. 139°, and  $\text{CMe}_2$ , m.p. 99—101°, derivatives; *Me* ester hydrochloride, m.p. 99—102°; *Et* ester hydrochloride, m.p. 91—92°, and *o*-hydroxybenzylidene derivative, m.p. 212° of the *Et* ester); *Me*  $\alpha$ -carbamyldiazinoisohexoate, m.p. 110°; *Et*  $\alpha$ -nitrosohydrazinoisohexoate, m.p. 25—28°; *Et*  $\alpha$ -aminoisohexoate, b.p. 88°/11 mm.; *Et*  $\alpha$ -azidoisohexoate, b.p. 94°/14 mm., non-cryst.  $\alpha$ -azidoisohexoic acid m.p. 92—95° and Ag salts);  $\alpha$ -hydrazino-*n*-heptoic acid, m.p. 205—206° (decomp.) [Cu salt, rapid decomp. 110° after darkening at 100°; hydrochloride, m.p. (indef.) 126—145°;  $\text{:CHPh}$ , m.p. 109°, and *o*-hydroxybenzylidene, m.p. 140°, derivatives; hydrochloride, m.p. 157°, and *o*-hydroxybenzylidene derivative, m.p. 203°, of the *Me* ester; non-cryst. *Et* ester and its hydrochloride, m.p. 99°, and *o*-hydroxybenzylidene derivative, m.p. 152°]; *Et*  $\alpha$ -carbamyldiazino-*n*-heptoate, m.p. 94° (hydrochloride, m.p. 125°, immediately hydrolysed by  $\text{H}_2\text{O}$ ), which does not condense with  $\text{PhCHO}$  or *o*- $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ ; non-cryst. *Et*  $\alpha$ -nitrosohydrazino-*n*-heptoate; *Et*  $\alpha$ -amino-*n*-heptoate, b.p. 89°/12 mm., and its very hygroscopic hydrochloride; *Et*  $\alpha$ -azido-*n*-heptoate, b.p. 104°/13 mm., also derived from  $\text{Me}[\text{CH}_2]_4\cdot\text{CHBr}\cdot\text{CO}_2\text{Et}$  and  $\text{NaN}_3$ ; non-cryst.  $\alpha$ -azido-*n*-heptoic acid (Ag salt):  $\alpha$ -hydrazino-*n*-nonoic acid, m.p. 197° ( $\text{:CHPh}$ , m.p. 117°, and *o*-hydroxybenzylidene, m.p. 137°, derivatives; hydrochloride, m.p. 166° after some decomp., and *o*-hydroxybenzylidene derivative, m.p. 132°, of the *Me* ester; *Et* ester hydrochloride, m.p. 72°); *Et*  $\alpha$ -carbamyldiazino-*n*-nonoate, m.p. 81°, which does not condense with  $\text{PhCHO}$  or *o*- $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ ; *Et*  $\alpha$ -nitrosohydrazino-*n*-nonoate; *Et*  $\alpha$ -amino-*n*-nonoate, b.p. 132°/17 mm.,  $\alpha$ -amino-*n*-nonoic acid, sublimes at about 256° (Cu salt, also  $+1\text{H}_2\text{O}$ ); *Et*  $\alpha$ -azido-*n*-nonoate, b.p. 140—145°/15 mm.; non-cryst.  $\alpha$ -azido-*n*-nonoic acid (Ag salt).

H. W.

**Imidocarbonic esters, iminothio-, oximinothio-, and dithio-formic esters.** J. HOUBEN and R. ZIVADINOVITSCH (Ber., 1936, 69, [B], 2352—2360).—Improvements in the prep. of  $\text{Et}_2$  *N*-chloroimidocarbonate (Sandmeyer, A., 1886, 611; Houben *et al.*, A., 1923, i, 1077) give the compound in 53·6—59% yield; it can be kept unchanged in light petrol-

eum.  $\text{Et}_2$  imidocarbonate (I), b.p. 40°/12 mm., can be kept unchanged (sealed) over anhyd. CaO. When kept alone (sealed) even in the dark it is slowly converted into a solution of  $\text{Et}_3$  isocyanurate in  $\text{EtOH}$ ; under similar conditions, but in presence of granulated  $\text{CaCl}_2$ ,  $\text{Et}_3$  cyanurate results. It is converted by dil. aq. alkali or by prolonged warming with  $\text{H}_2\text{O}$  into  $\text{EtOH}$  and  $\text{NH}_2\cdot\text{CO}_2\text{Et}$ . With solid alkali it affords  $\text{EtOH}$  or alkoxide and "isocyanate." An improved prep. of  $\text{Et}_2$  di-imido-oxalate, b.p. 69—70°/18 mm., is described. (I) in  $\text{Et}_2\text{O}$  is transformed by  $\text{NH}_2\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}\cdot\text{HCl}$  in  $\text{H}_2\text{O}$  into *Et* diethoxymethyleneaminoacetate,  $(\text{OEt})_2\text{C}=\text{N}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ , b.p. 108—109·5°/11 mm., in 66% yield. (I) and *p*- $\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{NH}_2\cdot\text{HCl}$  in abs.  $\text{EtOH}$  at room temp. afford *Et* *p*-tolylimidocarbonate, b.p. 135—136°/12 mm., but reaction does not occur with *o*- $\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{NH}_2\cdot\text{HCl}$ .  $\text{KNO}_2$  and  $\text{CH}_2(\text{OEt})_2$  are produced by the action of solid KOH on (I) in  $\text{Et}_2\text{O}$ . Anhyd. HCN combines with mercaptans in presence of HCl, but the products are usually non-cryst. oils which cannot be transformed into the corresponding oximino-compounds;  $\text{CH}_2\text{Ph}\cdot\text{SH}$ , however, gives *CH*<sub>2</sub>*Ph* imidothioformate hydrochloride (II), decomp. about 180°. Treatment of  $\text{EtSH}$  and HCN with HCl in light petroleum affords a non-cryst. product, transformed by  $\text{NH}_2\text{OH}\cdot\text{HCl}$  in  $\text{Et}_2\text{O}$  into *Et* thioformhydroxamate,  $\text{OH}\cdot\text{N}(\text{CH}_2\text{SEt})$ , m.p. 110—111°; the corresponding *Bu*<sup>a</sup>, m.p. 90—91°, and *CH*<sub>2</sub>*Ph*, m.p. 116—117°, esters are similarly obtained. *CH*<sub>2</sub>*Ph* thioformate has b.p. 109—111°/26 mm. (II) is converted by the successive action of  $\text{K}_2\text{CO}_3$  in  $\text{H}_2\text{O}$ - $\text{Et}_2\text{O}$  and  $\text{H}_2\text{S}$  into *CH*<sub>2</sub>*Ph* dithioformate, b.p. 161—162°/13 mm.  $\text{MeCN}$  and  $\text{CH}_2\text{Ph}\cdot\text{SH}$  give *CH*<sub>2</sub>*Ph* imidothioacetate hydrochloride, m.p. 153—155°.  $\text{SH}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$  and  $\text{MeCN}$  afford *Et*  $\alpha$ -imidoethylthiolacetate hydrochloride, m.p. 100—102°.  $\text{SH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  similarly gives  $\alpha$ -iminoethylthiolacetic acid hydrochloride, m.p. 110—112° (decomp.), transformed by KOH into the corresponding (?) acid, m.p. 97—98°.  $\text{NH}_4$  acetylthiolacetate, m.p. 68—70°, and acetylthiolacetamide, m.p. 78—80°, are incidentally described.

H. W.

**Reaction of halogenoamines with ketens.** G. H. COLEMAN, R. L. PETERSON, and G. E. GORFEN (J. Amer. Chem. Soc., 1936, 58, 1874—1876).— $\text{NH}_2\text{Cl}$  and  $\text{CH}_2\text{CO}$  in  $\text{Et}_2\text{O}$  at  $-60^\circ$  and then at room temp. give 73% of acetichloroamide, m.p. 111—112°;  $\text{NHBr}_2$  similarly affords 18% of bromoacetamide, m.p. 88—89° ( $\text{CH}_2\text{Br}\cdot\text{CO}\cdot\text{NHBr}$  is probably first formed and then reacts with the HBr produced in the reaction),  $\text{NCl}_3$  furnishes 14% of  $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{NH}_2$ , and  $\text{NMe}_2\text{Cl}$  yields (probably) chloroacetdimethylamide, b.p. 98—100°/11 mm.  $\text{CPh}_2\cdot\text{CO}$  (modified prep.; cf. Ritter and Wiedemann, A., 1930, 214) and  $\text{NH}_2\text{Cl}$  similarly give 51% of diphenylchloroacetamide, m.p. 116—117°;  $\text{NMe}_2\text{Cl}$  affords 95% of  $\text{CPh}_2\text{Cl}\cdot\text{CO}\cdot\text{NMe}_2$ , m.p. 122—123°, whilst  $\text{NCl}_3$  furnishes (cf. A., 1928, 1362) (probably) diphenylchloroacetdichloroamide, m.p. 112° (Cu block).

H. B.

**Monosodiocarbamide and its reactions.** R. A. JACOBSON (J. Amer. Chem. Soc., 1936, 58, 1984—1986).—Na (1 equiv.) reacts readily with  $\text{CO}(\text{NH}_2)_2$  in liquid  $\text{NH}_3$  to give the  $\text{Na}_1$  derivative (I), decomp. from 150—160°; reaction is slow with  $>1$  equiv. of

Na and affords (I) + Na, derivative. Oleyl- (II), stearyl-, and benzoyl- (III) -carbamide are obtained from (I) and  $\text{RCOCl}$ ;  $\text{CH}_3\text{PhCl}$  in liquid  $\text{NH}_3$  gives benzylcarbamide. (II), (III), and  $\text{NH}_2\cdot\text{CO}\cdot\text{NHAc}$  are formed from (I) and Me oleate, MeOBz, and EtOAc, respectively, in  $\text{COMe}_2$ . (I) and  $\text{CHR}(\text{CO}_2\text{Et})_2$  in  $\text{COMe}_2$  afford barbituric acid and its 5-Et, -Pr $^\beta$ , and -Bu derivatives. (I) and Et glutarate similarly give a compound, probably  $[\text{CH}_2]_3(\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}_2)_2$ , m.p. 247—248°; Et pimelate affords a similar compound, m.p. 240—245°, and a little of (probably) the compound  $\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}[\text{CH}_2]_5\cdot\text{CO}_2\text{H}$ , m.p. 205—206°. Mixed acylcarbamides are obtained from (I) and various oils (coconut, linseed, China wood) in  $\text{COMe}_2$ . (I) does not react with BuI or dodecyl bromide. H. B.

**Improved preparation of enolphosphopyruvic acid.** W. KIESSLING (Ber., 1936, 69, [B], 2331—2332; cf. A., 1935, 731).—Isolation is effected through the Ba salt. Ill-defined impurities containing P (probably phosphorylated products from condensed  $\text{AcCO}_2\text{H}$ ) are removed as their Na salts in slightly alkaline solution ( $p_H$  8.5) by treatment with EtOH, whilst P-free by-products are eliminated by taking advantage of the sparing solubility of Ba enolphosphopyruvate in hot solution and its fractional pptn. with EtOH from solution acid to litmus. H. W.

**Constitution of complex metallic salts. IV. Bridged dipalladium derivatives.** F. G. MANN and D. PURDIE (J.C.S., 1936, 873—890).—In the abstract of this paper (this vol., 1184) the following should have been recorded: *dichlorobis(triethylphosphine)-μ-dichlorodipalladium*, m.p. 230°, and the corresponding  $\text{Pr}^a$ , m.p. 189°, and  $\text{Bu}^a$  compound, m.p. 145°; *di-iodobis(tri-n-butylphosphine)-μ-di-iodopalladium*, m.p. 136° and the corresponding *n-amyl* compound, m.p. 127°; *dichlorobis(trimethylarsine)-μ-dichloropalladium*, decomp. 252—260° without melting, and the corresponding *Et*, m.p. 212°,  $\text{Pr}^a$ , m.p. 160°,  $\text{Bu}^a$ , m.p. 128°, and *n-amyl* compound, m.p. 108°; *dichloro-, dinitro-, and oxalato-dipyridylpalladium; oxalatobis-(n-butylphosphine)-μ-dichlorodipalladium*, m.p. 185—186° (decomp.) in bath at 180°; *dinitritobis-(n-butylphosphine)-μ-dinitritopalladium*, m.p. 138° (decomp.), and its additive compound with  $\text{NaNO}_2$ ; *oxalatobis-(n-butylphosphine)-μ-dinitritodipalladium*, m.p. 201—204° (decomp.) in bath at 185°; *dinitritobis-(n-butylphosphine)palladium*, m.p. 140°; *dichloro-* (I), m.p. 101° (corresponding  $\text{Pr}^a$  compound, m.p. 151°), and *dithiocyanato-bis-(n-butylarsine)-μ-dithiocyanatodipalladium* (II), m.p. 111° (corresponding  $\text{Pr}^a$  compound, m.p. 142°); *dithiocyanatobis-(n-butylarsine)palladium* (III), m.p. 75° (corresponding  $\text{Pr}^a$  compound, m.p. 90—91.5°); *dinitrito-*, m.p. 86—88°, and *dichloro-mono-p-toluidinomono-n-butylphosphinepalladium*, m.p. 75° (corresponding *anilino*-compound, m.p. 68°, and *arsine*, m.p. 87°); *dichloro-monoammino-*, m.p. 71°, and *tri-ammino-n-butylphosphinepalladium dichloride*; *bis-(n-butylphosphine)-bis(ethylenediamino)-μ-dichlorodipalladium dichloride*; *monochloro-n-butylphosphine-ethylenediaminopalladium monochloride*; *monochloroethylthiobis-(n-butylphosphine)-μ-dichlorodipalladium*, m.p. 151°, and

*dichlorobis-(n-octylsulphide)-μ-dichlorodipalladium*, m.p. 61°. *Phosphines* corresponding with (I), (II), and (III) have m.p. 142°, 165°, and 112°, respectively. F. N. W.

**Phenylcyclopentane and its behaviour towards catalytic hydrogenation.** J. I. DENISENKO (J. Gen. Chem. Russ., 1936, 6, 922—924).—Contrary to the tension theory of Baeyer, the *cyclopentane* ring is broken by hydrogenation. Phenylcyclopentane, b.p. 216—218°/750 mm., when passed over Pt at 305—310° in  $\text{H}_2$  yields a mixture of  $\alpha$ -,  $\beta$ -, and  $\gamma$ -phenylpentane. J. J. B.

**Action of bromine water on ethylenic compounds. Action on cyclohexene.** F. SWARTS (Bull. Acad. roy. Belg., 1936, [v], 22, 924—932; cf. this vol., 712).—*cyclohexene* with Br in  $\text{H}_2\text{O}$  at <20° affords 1:2-dibromocyclohexane (I), m.p. 2.8°, 2-bromocyclohexanol (II), m.p. 27.5°, identified as the 2- $\text{NH}_2$ -compound, and 2:2'-dibromodicyclohexyl ether (III), m.p. 70° (cf. A., 1925, i, 497). The ratio (II)/(I) is the greater the higher is the reaction temp. (cf. A., 1928, 505, 866). (II) when heated in vac. at 110° does not afford (III), which indicates that (III) does not arise from (II). Heat decomposes (III) but some *cyclohexylcyclohexene* is formed; when heated with  $\text{PCl}_3$  and Br under pressure (III) affords some (I). J. L. D.

**Oxidation of  $\alpha\alpha\alpha\epsilon$ -tetraphenyl- $\Delta^{\alpha\delta}$ -pentadiene and  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\alpha\epsilon}$ -hexadiene.** K. H. BAUER and H. HERZOG (J. pr. Chem., 1936, [ii], 147, 4—10).— $\text{CH}_2(\text{CH}\cdot\text{CPh}_2)_2$  (I) with  $\text{H}_2$ -Pd-BaSO $_4$  in  $\text{C}_6\text{H}_6$  gives  $\text{CHPh}_2\cdot[\text{CH}_2]_3\cdot\text{CHPh}_2$  and with Br- $\text{CHCl}_3$  gives HBr and  $\beta\delta$ -dibromo- $\alpha\alpha\epsilon\epsilon$ -tetraphenyl- $\Delta^{\alpha\delta}$ -pentadiene, m.p. 141°.  $\text{Bz}\cdot[\text{CH}_2]_4\cdot\text{Bz}$  and  $\text{MgPhBr}$  in  $\text{Et}_2\text{O}$  give  $\alpha\alpha\zeta\zeta$ -tetraphenylhexane- $\alpha\zeta$ -diol, m.p. 213°, dehydrated at 230° to give  $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\alpha\epsilon}$ -hexadiene (II), m.p. 108—109°, which with  $\text{H}_2$ -Pd-BaSO $_4$  gives  $\alpha\alpha$ -tetraphenylhexane, m.p. 123—124°; the tetrabromide, m.p. 146—147° (decomp.), of (II) in hot EtOH gives HBr and  $\beta\epsilon$ -dibromo- $\alpha\alpha\zeta\zeta$ -tetraphenyl- $\Delta^{\alpha\epsilon}$ -hexadiene, m.p. 199°. With  $\text{BzO}_2\text{H}\cdot\text{CHCl}_3$  (II) yields  $\alpha\alpha\zeta\zeta$ -tetraphenylhexane- $\alpha\beta\epsilon\zeta$ -tetraol, m.p. 193°. Owing to the presence of  $\text{:C}\cdot\text{CH}_2\cdot\text{C:}$  oxidation of (I) at 100° or in ultra-violet light at room temp. is faster than that of (II); in both cases  $\text{COPh}_2$  is formed. R. S. C.

**Colorimetric determination of carotenoids by a modified potassium dichromate method.** A. KROGIS (Biochem. Z., 1936, 287, 226—234; cf. Jørgensen, A., 1927, 952).—The alterations which must be made in the  $p_H$  of aq.  $\text{K}_2\text{Cr}_2\text{O}_7$  used as colour standard in determining various concns. of carotene (I) and xanthophyll (II) have been measured for layers 1—35 mm. thick at intervals of 1 mm. Consequently (I) and (II) can be determined with the help of buffered aq.  $\text{K}_2\text{Cr}_2\text{O}_7$  as standard, the accuracy attainable being as great as that of the method of Kuhn *et al.* (A., 1932, 785), which is not applicable to the higher and lower concns. covered by the new method. For very low concns. the method of Connor (A., 1928, 786) should be applied. W. McC.

**Carotenoids of purple bacteria.**—See this vol., 1561.

Is the methyl group attached to the benzene nucleus positive or negative? W. HEROLD and K. W. ROSENMUND (J. pr. Chem., 1936, [ii], 146, 201—208; cf. this vol., 105).—In reply to Huntenburg (this vol., 1239) it is shown that conclusions based on Hund's theory (A., 1925, ii, 479), the results of absorption measurements of  $C_6H_6$  derivatives, chemical evidence, and analyses of band spectra are in harmony with the view that Me acts as a positive substituent in the  $C_6H_6$  nucleus. H. W.

**Mechanism of aromatic side-chain reactions with special reference to the polar effects of substituents. VIII. Polar effects of halogens.** J. W. BAKER (J.C.S., 1936, 1448—1451; cf. this vol., 195).—The order for the velocity of interaction of the *m*-halogenobenzyl bromides with  $C_5H_5N$  in dry  $COMe_2$  ( $I > Br \sim Cl > F$ ) is in agreement with that of Bennett *et al.* (*ibid.*, 165) for the corresponding chlorides. The velocity order for the corresponding *p*-compounds ( $F \sim I > Br > Cl$ ) differs from that of Bennett *et al.*, who used aq.  $COMe_2$ . These results are explained in terms of resonance between

The following were prepared from the appropriate halogenotoluene with Br: *m*-fluoro-, b.p.  $87^\circ/17$  mm., *p*-fluoro-, b.p.  $38^\circ/0.6$  mm., *m*-chloro-, b.p.  $55^\circ/0.2$  mm., m.p.  $17.5^\circ$ , and *m*-iodo-, m.p.  $50.8^\circ$ , -benzyl bromide.

F. R. G.

**Natural and synthetic rubber. XVI. Structure of polystyrene.** T. MIDGLEY, jun., A. L. HENNE, and H. M. LEICESTER (J. Amer. Chem. Soc., 1936, 58, 1961—1963).—Contrary to Staudinger (cf. A., 1935, 740), polystyrene (I) is

$-CH_2-CHPh-CHPh-CH_2-CH_2-CHPh-CHPh-CH_2-$ , since styrene+Na with EtOH give PhEt (74%) and  $(CH_2Ph-CH_2)_2$  (about 23%). This structure is the only one consistent with Mack's explanation (B., 1935, 196) of the elastic properties of (I). H. B.

**Reactivity of the methyl group in some nitrodiphenylmethanes.** G. D. PARKES and R. H. H. MORLEY (J.C.S., 1936, 1478—1479).—The influence of the position of  $NO_2$  groups on the reaction between nitrodiphenylmethanes and *p*-NO- $C_6H_4$ -NMe<sub>2</sub> (I) results in the formation of 4:4'-dinitro-, m.p.  $155^\circ$ , and 2:4:2':4'-tetranitro-benzophenone-*p*-dimethyl-aminoanil, m.p.  $143^\circ$  (decomp.), and of coloured products from 2:2'-dinitro- (II) and 2:4:6:2':4'-pentanitro-, m.p.  $200^\circ$ , obtained by nitration of 2:4:2':4'-tetranitro-diphenylmethane (III). The  $(NO_2)_6$ -compound could not be prepared, and the 3:3'-( $NO_2$ )<sub>2</sub>-compound and  $CH_2Ph_2$  do not react with (I). The anils of the (II) and (III) exceptionally resist hydrolysis. These nitrodiphenylmethanes do not couple with diazonium salts. F. R. G.

**Reaction of sodium with triphenylmethyl chloride and triphenylmethyl in organic solvents.** W. E. BACHMANN and F. Y. WISELOGLE (J. Amer. Chem. Soc., 1936, 58, 1943—1944).—Na (excess) reacts rapidly with  $CPh_3Cl$  in  $Et_2O$  or  $Et_2O-C_6H_6$ , and more slowly in  $C_6H_6$  (cf. Morton and Stevens, A., 1932, 728), to give  $CPh_3$  and thence  $NaCPh_3$ , if the metal surface is exposed throughout the reaction. When the complete reaction is slow (e.g., use of 1

atom of Na) a little *p*-benzhydryltetraphenylmethane is also produced (cf. Schlenk and Marcus, A., 1914, i, 823).  $NaCPh_3$  is oxidised (dry air) to  $CPh_3 \cdot OH$  and a little  $(CPh_3 \cdot O)_2$ . H. B.

**Allotropic forms of diphenyl sulphone and determination of their transition point.** V. J. MIKESKA, N. T. FARINACCI, and M. T. BOGERT (J. Amer. Chem. Soc., 1936, 58, 1869—1871).—Crystallisation (any method) of  $Ph_2SO_2$  at  $>75^\circ$  gives a form, m.p.  $128^\circ$  (I); at  $<75^\circ$  a form, m.p.  $124^\circ$  (II), results. (I) and (II) are reciprocally convertible allotropic forms; the transition temp. is  $74.8^\circ$  (determination described). Discrepancies in the lit. are thus explained. H. B.

**Destructive catalysis of hydrindene and hydrindane.** M. B. TUROVA-POLLAK (J. Gen. Chem. Russ., 1936, 6, 947—949).—Hydrogenation of hydrindene (I) at  $360-380^\circ$  in presence of Pt affords mainly *o*- $C_6H_4$ MeEt, converted by Br and  $AlBr_3$  into  $C_6MeBr_5$ . Hydrindane at  $300-330^\circ$  gives chiefly (I). J. J. B.

**Dipole moments and the fixation of aromatic double links: bromohydrindenes and bromotetralins.** N. V. SIDGWICK and H. D. SPRINGALL (J.C.S., 1936, 1532—1537).—6-Bromo-5-aminohydrindene and 6-bromo-7-aminotetrahydronaphthalene with  $Cu_2Br_2$  (Sandmeyer) yield respectively 5:6-dibromohydrindene (I), m.p.  $76-77^\circ$ , and 6:7-dibromotetrahydronaphthalene (II), m.p.  $54-55^\circ$ . The following dipole moments have been measured: hydrindene, 0.53D; 6-bromo-, 2.15D, and 5:6-dibromo-hydrindene, 2.48D; tetrahydronaphthalene, 0.52D; 7-bromo-, 2.23D, and 6:7-dibromo-tetrahydronaphthalene, 2.81D; 4-bromo-, 2.07D, and 4:5-dibromo-*o*-xylene, 2.86D; *o*- $C_6H_4Br_2$ , 2.12D. Hence it is calc. that the moment of the aromatic Br-C-C-Br system is 2.12D; this val. is found for (I) but for (II) it is 1.78D owing to fixation of the double linkings (cf. Mills *et al.*, A., 1931, 83). F. R. G.

**1-Vinylnaphthalene and certain of its derivatives.** J. S. SALKIND and S. A. ZONIS (J. Gen. Chem. Russ., 1936, 6, 988—998).—The following 1-vinylnaphthalene (I) derivatives have been prepared by dehydrating the appropriate alcohols with  $KHSO_4$  ( $R = \alpha-C_{10}H_7$ ): (I), from  $OH \cdot CH_2 \cdot CH_2R$ ;  $CHR \cdot CHMe$ , from 1- $\alpha$ -hydroxy-*n*-propyl-, m.p.  $58-59^\circ$ , b.p.  $139-140^\circ/4$  mm. (from EtCHO and  $MgRBr$ );  $CRMe \cdot CH_2$ , from  $OH \cdot CRMe$ ; 1- $\alpha$ -methyl- $\Delta^a$ -propenyl-, b.p.  $113.5-115^\circ/5$  mm., from 1- $\alpha$ -hydroxy- $\alpha$ -methyl-*n*-propyl-, m.p.  $49-50^\circ$ , b.p.  $146-147^\circ/4$  mm. (picrate, m.p.  $138-139^\circ$ ) (from  $COMeEt$  and  $MgRBr$ ); 1- $\alpha$ -ethyl- $\Delta^a$ -propenyl-, b.p.  $119-120.5^\circ/6$  mm., from 1- $\alpha$ -hydroxy- $\alpha$ -ethyl-*n*-propyl-, m.p.  $42-43^\circ$ , b.p.  $145-146^\circ/3$  mm. (picrate, m.p.  $131-132^\circ$ ) (from  $COEt_2$  and  $MgRBr$ ) -naphthalene. The velocity of polymerisation of the hydrocarbons falls in the order given, in presence or absence of catalysts ( $BzO_2H$ , folidin), and, except in the case of (I), the products consist chiefly of the dimerides. R. T.

**cycloHexylnaphthalenes and related compounds.** J. W. COOK and C. A. LAWRENCE (J.C.S., 1936, 1431—1434).—Hydrogenation (Adams) of 1-(1'-naphthyl)- $\Delta^1$ -cyclohexene (I) takes place very

slowly owing to mutual saturation of free affinities at  $C_{12}$  and  $C_{18}$ , to give 1-cyclohexylnaphthalene (II) (cf. Bodroux, A., 1929, 1050). 1-Keto-1:2:3:4-tetrahydronaphthalene with Mg cyclohexyl chloride gives (probably) 1-keto-2-(1'-tetrahydronaphthylidene)-1:2:3:4-tetrahydronaphthalene, m.p. 130—130.5° [2:4-dinitrophenylhydrazones, m.p. 249—250° (decomp.)], and 1-cyclohexyl-3:4-dihydronaphthalene, b.p. 140°/1 mm., 172°/10 mm., dehydrogenated to (II), b.p. 118—120°/0.3 mm. [picrate, m.p. 122—123.5°; styphnate, m.p. 150.5—151°;  $s\text{-C}_6\text{H}_3(\text{NO}_2)_3$  compound, m.p. 116.5—117.5°]; the derivatives of (I) do not depress the m.p. of those of (II). (II) and its 2-isomeride are not dehydrogenated by Pt-black, whilst (II) remains unchanged with Se. The Li compound of 5-bromo-1:2:3:4-tetrahydronaphthalene with cyclohexene oxide gives 2-(5'-tetrahydronaphthyl)cyclohexanol, a gum (3:5-dinitrobenzoate, m.p. 163—164.5°), oxidised ( $\text{H}_2\text{CrO}_4$ , AcOH) to the corresponding cyclohexanone [semicarbazone, m.p. 198—200° (decomp.)] and dehydrated ( $\text{ZnCl}_2$ ) to 1-(5'-tetrahydronaphthyl)- $\Delta^1$ -cyclohexene, b.p. 181°/15 mm., which was hydrogenated (Adams) rapidly [in contrast to (I)] to 5-cyclohexyl-1:2:3:4-tetrahydronaphthalene, b.p. 118°/0.2 mm. The carbinol from 2-methylcyclohexanone and  $1\text{-C}_{10}\text{H}_7\text{-MgBr}$  when dehydrated ( $\text{KHSO}_4$ ) gives 1-(1'-naphthyl)-2-methyl- $\Delta^1$ -cyclohexene, b.p. 125°/0.3 mm., dehydrogenated (Se) to 1-o-tolyl-naphthalene, m.p. 67.5—68.5° and cyclised ( $\text{AlCl}_3$ ,  $\text{CS}_2$ ) unlike (I) to a compound, b.p. 122—130°/0.3 mm., dehydrogenated (Se) to fluoranthene.  $n_D$  and  $d$  are recorded for some of the above compounds.

F. R. G.

**Nitro-derivatives of fluorene. II. Colour reactions given by some derivatives of 2-nitrofluorene.** C. CANDEA and E. MACOVSKI (Bull. Soc. chim., 1936, [v], 3, 1761—1767).—In presence of piperidine, 2-nitrofluorene and  $p\text{-C}_6\text{H}_4\text{Me-CHO}$  or piperonal give 2-nitro-9-*p*-tolylidene- and -9-piperonylidene-fluorene. With  $p\text{-OH-C}_6\text{H}_4\text{-CHO}$ , the -9-*p*-hydroxybenzylidene compound (I), m.p. 207—208° (Bz derivative (II), m.p. 214—215°), is formed. The vanillylidene compound (A., 1935, 1488) is reduced ( $\text{Zn-CaCl}_2$ ) to 2-amino-9-vanillylidene-fluorene (III), m.p. 190—191°. With KOH in EtOH or  $\text{COMe}_2$ , (II) gives an intense red, (I) a feeble red, and (III) a pale yellow colour.

E. W. W.

**2:3-cyclopentenonaphthalene.** S. C. S. GUPTA (Current Sci., 1936, 5, 133).— $\gamma$ -Keto- $\gamma$ -5-hydrindyl-n-butyric acid, m.p. 123—124° [obtained by condensing  $(\text{CH}_2\text{CO})_2\text{O}$  and hydrindine in presence of  $\text{AlCl}_3$ ] is reduced (Clemmensen) to  $\gamma$ -5-hydrindyl-n-butyric acid, m.p. 56°; this on cyclisation (85%  $\text{H}_2\text{SO}_4$ ) affords 1-keto-6:7-cyclopenteno-1:2:3:4-tetrahydronaphthalene, b.p. 167°/6 mm., which is reduced (Clemmensen) to 6:7-cyclopenteno-1:2:3:4-tetrahydronaphthalene, b.p. 125—126°/6 mm., and this in turn yields 2:3-cyclopentenonaphthalene, m.p. 94° (picrate, m.p. 120—121°), on dehydrogenation (Se; 300—340°).

F. N. W.

**Retarding agents in the chlorination of anthracene.** Influence of the nature of the solvent on the progress of the reaction. M. ILJINSKI and V. AFREMOV (Compt. rend. Acad. Sci. U.R.S.S., 1936,

3, 135—136).—The rate of chlorination of anthracene by  $\text{SO}_2\text{Cl}_2$  is largely influenced by traces of impurity; the effect of the solvent ( $\text{CCl}_4$  or xylene) varies with the purity of the sample of anthracene used.

A. J. E. W.

(A) Phenanthrene-bromine addition reaction. C. C. PRICE. (B) Effect of substituents on phenanthrene-bromine addition reaction. L. F. FIESER and C. C. PRICE (J. Amer. Chem. Soc., 1936, 58, 1834—1838, 1838—1843).—(A) The equilibrium consts. ( $K$ ) for the reaction  $\text{C}_{14}\text{H}_{10} + \text{Br}_2 \rightleftharpoons \text{C}_{14}\text{H}_9\text{Br}_2$  (in  $\text{CCl}_4$ ; Br determined colorimetrically with a Keuffel and Esser spectrophotometer) are  $340 \pm 8$ ,  $230 \pm 6$ , and  $134 \pm 2$  at 15.7°, 25°, and 39°, respectively.  $\text{O}_2$ ,  $\text{Bz}_2\text{O}_2$ , and  $\beta\text{-C}_{10}\text{H}_7\text{-OH}$  have no effect but  $\text{NHPh}_2$ , quinol, and tetrabromo-quinol and -pyrocatechol are effective inhibitors even in relatively small amounts. A chain mechanism and method for the determination of its length are discussed. Addition of phenanthrene (I) to Br in dioxan (II) (solution stable at room temp.) causes bromination of (II) ( $\frac{2}{3}$ ) and addition to (I) ( $\frac{1}{3}$ ).

(B) The nos. quoted after the following derivatives of phenanthrene are the  $K$  at 25° and 36° (unless stated otherwise), respectively: 2- $\text{CO}_2\text{Et}$ -, 168, 88; 3- $\text{CO}_2\text{Et}$ -, 93, 59; 2- $\text{CO}_2\text{Me}$ -, 167, 81; 3- $\text{CO}_2\text{Me}$ -, 129, 63; 2-Cl-, 159, 54; 3-Cl-, 170, 67; 2-Br-, 152, 59; 3-Br-, 152, 69; 2- $\text{Bu}^{\gamma}$ -, 320, 262 (at 37.4°); 3- $\text{Bu}^{\gamma}$ -, 467, 191 (at 37.4°). Hal and  $\text{CO}_2\text{Me}(\text{Et})$  (more effective in 3- than 2-position), i.e., groups which retard substitution in the  $\text{C}_6\text{H}_6$  ring, decrease the free energy of the 9:10-addition of Br, whilst  $\text{Bu}^{\gamma}$  (which facilitates substitution) causes an increase; these results parallel those obtained (A., 1929, 1452) for the free energy of oxidation of 9:10-dihydroxyphenanthrenes. A sp. decrease in the reaction velocity is found for the 2-Hal (i.e., *m*-position). Et, OMe, and NHAc substituents lead to irreversible absorption of  $>1$  mol. of  $\text{Br}_2$ .

$\text{PhBu}^{\gamma}$ ,  $(\text{CH}_2\text{CO})_2\text{O}$ , and  $\text{AlCl}_3$  in  $\text{CS}_2$  give  $\beta$ -*p*-tert.-butylbenzoylpropionic acid, dimorphous, both m.p. 121—122° [oxidised (KOCl) to  $p\text{-C}_6\text{H}_4\text{Bu}^{\gamma}\text{-CO}_2\text{H}$  and thence (dil.  $\text{HNO}_3$ ) to  $p\text{-C}_6\text{H}_4(\text{CO}_2\text{H})_2$ ], reduced (modified Clemmensen; this vol., 1249) to  $\gamma$ -*p*-tert.-butylphenylbutyric acid, m.p. 59.5—60.5°, the Et ester, b.p. 145—147°/5 mm., of which with  $\text{Et}_2\text{C}_2\text{O}_4$  (method: A., 1935, 1495) followed by 80%  $\text{H}_2\text{SO}_4$  at 60° affords 7-tert.-butyl-3:4-dihydronaphthalene-1:2-dicarboxylic anhydride (I), m.p. 143—145°, and a little of an isomeride, m.p. 174—175°. (I) is dehydrogenated (S at 330—340°) to 7-tert.-butyl-naphthalene-1:2-dicarboxylic anhydride, m.p. 146.5—147.5°.  $(\text{CH}_2\text{CH})_2$  and (I) at 150° give 6-tert.-butyl-1:4:9:10:11:12-hexahydrophenanthrene-11:12-dicarboxylic anhydride, m.p. 85.5—86.5°, converted by KOH at 330—360° (method: this vol., 203) into a product which is dehydrogenated (Se) to 3-tert.-butylphenanthrene, m.p. 54—55° (picrate, m.p. 142—143°; quinone, m.p. 186—187°). 2- $\text{C}_{10}\text{H}_7\text{Bu}^{\gamma}$ ,  $(\text{CH}_2\text{CO})_2\text{O}$ , and  $\text{AlCl}_3$  in cold  $\text{PhNO}_2$  afford  $\beta$ -6-tert.-butyl-2-naphthoylpropionic acid, m.p. 148—150°, reduced (as above) to  $\gamma$ -6-tert.-butyl-2-naphthylbutyric acid, ? dimorphous, m.p. 87—95°, the chloride of which with  $\text{AlCl}_3$  in cold  $\text{CS}_2$  gives 1-keto-7-tert.-butyl-1:2:3:4-tetrahydrophenanthrene (picrate,

m.p. 107—108°), converted by successive reduction and dehydrogenation (Se at 320—350°) into 2-*tert*-butylphenanthrene, m.p. 99—100° (picrate, m.p. 130—131°; quinone, m.p. 129—130°). 2-Acetylphenanthrene and MgMeI in Et<sub>2</sub>O-C<sub>6</sub>H<sub>6</sub> afford 2-phenanthryldimethylcarbinol, dimorphous, m.p. 90—92° (decomp.) and 97—99° (decomp.); recrystallisation of 3-phenanthryldimethylcarbinol picrate, m.p. 107—110° (decomp.), from EtOH gives (probably) 3-isopropenylphenanthrene picrate, m.p. 160—163° (decomp.). C<sub>10</sub>H<sub>8</sub>, Bu<sup>γ</sup>Cl, and a little AlCl<sub>3</sub> afford (cf. Gump, A., 1931, 341) 2-C<sub>10</sub>H<sub>7</sub>Bu<sup>γ</sup> and two C<sub>10</sub>H<sub>6</sub>Bu<sup>γ</sup><sub>2</sub>, m.p. 86—90° (picrate, m.p. 155.5—156.5°) and 146—147° [oxidised (CrO<sub>3</sub>, AcOH) to a quinone, C<sub>18</sub>H<sub>22</sub>O<sub>2</sub>, m.p. 83.5—84.5°]. H. B.

**Synthesis of an isomeride of retene: 1-methyl-9-isopropylphenanthrene.** G. DARZENS and A. LEVY (Compt. rend., 1936, 203, 669—671).—Condensation of 1:4-C<sub>10</sub>H<sub>6</sub>Pr<sup>β</sup>·CH<sub>2</sub>Cl with Et malonate yields *Et* 4-isopropyl-1-naphthylmethylmalonate (I), a viscid liquid (acid, decomp. 170° to 4-isopropyl-naphthalene-1-propionic acid, m.p. 136°). The Na derivative of (I) is condensed with allyl bromide, and the resulting ester hydrolysed to the dibasic acid which decomposes at 170°, giving β-(4-isopropyl-1-naphthyl)-α-allylpropionic acid, a viscid liquid. Cyclisation of this acid with H<sub>2</sub>SO<sub>4</sub>+AcOH for 3 days at 40° gives a mixture of 1-methyl-9-isopropyl-1:2:3:4-tetrahydrophenanthrene-3-carboxylic acid (II), m.p. 160° [*Me* ester (III), b.p. 192—193°/4 mm.], and the lactone, b.p. 195—197°/4 mm., of β-(4-isopropyl-1-naphthyl)-α-γ-hydroxypropylpropionic acid. (III) when heated with S at 240° gave the *Me* ester, b.p. 195—196°/4 mm., of 1-methyl-9-isopropylphenanthrene-3-carboxylic acid, m.p. 204°. Se and (II) at 340° gave 1-methyl-9-isopropylphenanthrene, b.p. 204—205°/14 mm. (picrate, m.p. 143°; styphnate, m.p. 156°). Oxidation with CrO<sub>3</sub> gives 1-methylphenanthraquinone with elimination of Pr<sup>β</sup>. J. N. A.

**Constitution of hexahydropyrene.** J. W. COOK and C. L. HEWETT (Chem. and Ind., 1936, 843—844).—Pestemer *et al.* (this vol., 1048) have overlooked the authors' earlier work (A., 1933, 601) on the isolation and structures of two hexahydropyrenes.

J. W. B.

**Detection of 1:2-benzpyrene with the fluorescence spectrograph.** G. MIESCHER, F. ALMASY, and K. KLAU (Biochem. Z., 1936, 287, 189—197; cf. Sannie, this vol., 664; Mayneord, *ibid.*).—Pure 1:2-benzpyrene (I) in C<sub>6</sub>H<sub>14</sub> can be detected by its fluorescence spectrum in concns. <0.0025 mg. per litre; contamination with other fluorescent polycyclic hydrocarbons (*e.g.*, chrysene, phenanthrene, pyrene, retene, 1:2:5:6-dibenzanthracene, anthracene, 2-methylanthracene, fluoranthrene) singly and together does not seriously interfere with the detection. (I) in tar fractions is detected in the same way in 0.0003% concn. if basic impurities are removed with H<sub>2</sub>SO<sub>4</sub>.

W. McC.

**Naphthacene structure of rubenes.** I. II. The new structure: mechanism of formation, constitutions, and formulæ with corrected nomenclature. C. DUFRAISSE. III. Historical review and discussion of naphthacenes, their syntheses,

and their photochemical characteristics. IV. Naphthacene the prototype of the rubenes. V. Synthesis of phenylnaphthacenes of rubene character. C. DUFRAISSE and R. HORCLOIS. VI. Synthesis of 5:6:11:12-tetraphenylnaphthacene: its identity with tetraphenylrubene (formerly known as rubrene). C. DUFRAISSE and L. VELLUZ (Bull. Soc. chim., 1936, [v], 3, 1847—1857, 1857—1872, 1872—1880, 1880—1893, 1894—1905, 1905—1913).—I. Theoretical. The name "rubene" is abandoned: rubenes have not the structure (A) previously attributed to them, but are derivatives of naphthacene (B). Objections to A are discussed.

That naphthacenes, with which rubenes are now identified, have not structure A is shown by absorption spectra, and by the formation of photo-oxides. The structure of ψ-rubene is discussed.

II. Three possible mechanisms of the formation of "rubenes" (tetra-substituted naphthacenes) from CPhRCl·C:CR' are discussed: the prior formation of structure (A) (above); the intermediate formation of dibenzocyclodecadiene; and direct condensation. That the product has structure (C) (with central

symmetry) and not the alternative (D) (with planar symmetry), is shown by the fact that if R' is replaced by Cl, HCl is lost by two stages; thus 6:12-dichloro-5:11-diphenylnaphthacene (the former "3:3'-dichloro-1:1'-diphenylrubene") yields first 12-chloro-11-phenyl-5:6-phenylenenaphthacene ("3'-chloro-3-phenyl-1:1'-phenylenrubene"), and then 5:6:11:12-diphenylenenaphthacene ("1:1':3:3'-diphenylenrubene"). Revised names of rubene derivatives are recorded.

III. A review.

IV. Naphthacene (I) (improved prep. from tetramethyleneanthraquinone by passage over Zn at 300—400°, followed by passage over Zn at 700° or PbO at 400°) gives an absorption spectrum similar to that from "tetra-arylrubenes"; when exposed, in CS<sub>2</sub> solution, to sunlight, it absorbs O<sub>2</sub> to give a non-fluorescent photo-oxide [decomp. 120°, to resinous products, with little (I)], which is reduced by KI, with formation of benzanthrone. With HI, or KOH in C<sub>5</sub>H<sub>11</sub>·OH or CH<sub>2</sub>Ph·OH, (I) gives 5:12-dihydronaphthacene. (I) is not isomerised by H<sub>2</sub>SO<sub>4</sub> or other acids.

V. Naphthacenequinone (new prep. from 2:3-tetramethyleneanthraquinone, using PbO) with MgPhBr yields 5:12-dihydroxy-5:12-diphenyl-5:12-dihydronaphthacene (II), m.p. 251—252°, with two diphenyltetrahydronaphthacenequinones (cf. this vol., 992). (II) with KI, Na<sub>2</sub>PO<sub>3</sub>, and AcOH, or 6:11-diphenyl-1:2:3:4-tetrahydronaphthacene dehydrogenated, gives 5:12-diphenylnaphthacene (III), m.p.

207—208° (+0.5Et<sub>2</sub>O, m.p. 171—172°). Oxidation of (III) (heating in air, or action of H<sub>2</sub>SO<sub>4</sub>) gives violet 11-phenyl-5:6-phenylenenaphthacene, further oxidised by FeCl<sub>3</sub>-H<sub>2</sub>SO<sub>4</sub> to blue 5:6:11:12-diphenylenenaphthacene. With gaseous HI in CS<sub>2</sub>, (III) gives 5:12-diphenyl-5:12-dihydronaphthacene, m.p. 206—207°, reconverted into (III) by heating. (III) is very sensitive to light, yielding the 5:12(or 6:11)-photodioxide, decomp. 160°. 2:3-Tetramethylenanthraquinone and MgPhBr furnish 6:11-dihydroxy-6:11-diphenyl-1:2:3:4:6:11-hexahydronaphthacene, m.p. 239—240°, which on attempted dehydration gives only (III), and on reduction (KI-AcOH) gives 6:11-diphenyl-1:2:3:4-tetrahydronaphthacene (IV), m.p. 298° [6:11-photodioxide, m.p. 238°; decomp. to (IV) and O<sub>2</sub>]. The dissociability of naphthacene photo-oxides is discussed.

VI. Dihydroxynaphthacenequinone and MgPhBr give 5:6:11:12-tetrahydroxy-5:12-diphenyl-5:12-dihydronaphthacene (with some 6-hydroxy-11-phenylnaphthacene-5:12-quinone, m.p. 304—305°), converted on heating, alone or in AcOH, into 6:11-diphenylnaphthacene-5:12-quinone, m.p. 284—285°. This with MgPhBr yields 5:12-dihydroxy-5:6:11:12-tetraphenyl-5:12-dihydronaphthacene, m.p. 251° (+2C<sub>6</sub>H<sub>6</sub>, m.p. 185°), which when heated in AcOH loses H<sub>2</sub>O, forming 5:12-diphenyl-5:6:11:12-diphenylene-5:12-dihydronaphthacene, identical with "dehydro-rubrene," and is reduced by Na<sub>2</sub>PO<sub>3</sub>, KI, and AcOH to 5:6:11:12-tetraphenylnaphthacene, identical with tetraphenylnubene. E. W. W.

Oxidation of 5:6:11-triphenylnaphthacene in the light and in the dark. The photo-oxide, C<sub>36</sub>H<sub>24</sub>O<sub>2</sub>. M. BADOCHÉ (Bull. Soc. chim., 1936, [v], 3, 2040—2046).—5:6:11-Triphenylnaphthacene (I) (formerly triphenylrubene) (prep. described) has m.p. 236—237°, or +1C<sub>6</sub>H<sub>6</sub> which cannot be removed without decomp. of the mol., m.p. 177—178°. On exposure to sunlight in C<sub>6</sub>H<sub>6</sub> it readily absorbs O<sub>2</sub> giving 5:6:11-triphenylnaphthacene 5:12-dioxide (II) (+1C<sub>6</sub>H<sub>6</sub>), m.p. about 176—177°, which evolves a small amount of gas containing 85—90% of O<sub>2</sub> when heated at 140°/vac., and a larger proportion when heated rapidly over a naked flame. Little gas is evolved when it is heated progressively by itself or mixed with vaseline or sand. The constitution of (II) is advanced with reserve and is based mainly on its differing behaviour from 5:6:11:12-tetraphenylnaphthacene 5:12-dioxide and the analogous difference between the photo-oxides of anthracene and 9:10-diphenylanthracene. A conc. solution of (I) in C<sub>6</sub>H<sub>6</sub> over Hg slowly absorbs O<sub>2</sub> in the dark giving an oxide which does not appear identical with (II). H. W.

Isotopic exchange between aniline hydrochloride and heavy water.—See this vol., 1339.

Rearrangement of N-iodoformanilide in anisole solution.—See this vol., 1471.

Additive product of basic copper trichloroacetate with benzylamine. A. ABLOV (Bull. Soc. chim., 1936, [v], 3, 1915).—The compound,

CH<sub>2</sub>Ph·NH<sub>2</sub>, is prepared by treating Cu(O·CO·CCl<sub>3</sub>)<sub>2</sub> with A in EtOH. E. W. W.

Derivatives of 2:4-di- and 2:4:5-tri-methyl-aniline. G. VAN KLEEF (Rec. trav. chim., 1936, 55, 765—785).—Acet-*m*-4-xylylide, m.p. 130° (best prepared by boiling the base with AcOH), with HNO<sub>3</sub> (best, *d* 1.42) at 0° gives the 5-NO<sub>2</sub>- (Me:Me:NH<sub>2</sub>=1:3:4), m.p. 172° (cf. lit.), and with abs. HNO<sub>3</sub> the 5:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 220° (lit. 117°). *Me m*-4-xylylcarbamate [prep. from *as*-*m*-xylidine (I) and ClCO<sub>2</sub>Me in H<sub>2</sub>O at 0°], m.p. 79°, affords similarly the 5-NO<sub>2</sub>-, m.p. 134° [hydrolysed to 5-nitro-*m*-4-xylidine (II) by conc. H<sub>2</sub>SO<sub>4</sub> at 100°], and 5:6-(NO<sub>2</sub>)<sub>2</sub>- (III)-derivative, m.p. 218° (resistant to hydrolysis). Similarly are obtained Et *m*-4-xylylcarbamate, m.p. 59° (lit. 58°), and its 5-NO<sub>2</sub>-, m.p. 134° (lit. 125—126°) [hydrolysed by conc. H<sub>2</sub>SO<sub>4</sub> at 125—130° to (II)], and 5:6-(NO<sub>2</sub>)<sub>2</sub>-derivative (IV), m.p. 150° (hydrolysed similarly to 5:6-dinitro-*m*-4-xylidine). N-*m*-4-*Xylyl*-N'-methylcarbamide (prep. in C<sub>6</sub>H<sub>6</sub>), m.p. 170°, with HNO<sub>3</sub> (*d* 1.4) affords the 5-NO<sub>2</sub>-derivative, m.p. 230° [also obtained from (II) and PhNCO], and with abs. HNO<sub>3</sub> N-nitro-N-5:6-dinitro-*m*-4-xylyl-N'-methylcarbamide, unstable, which with hot abs. EtOH gives (IV), also obtained from (III). Similarly are prepared N-*m*-4-xylyl-N'-ethylcarbamide, m.p. 188°, and its 5-NO<sub>2</sub>-, m.p. 220°, and 5:6:N'-(NO<sub>2</sub>)<sub>3</sub>-derivative. *Me m*-4-xylyloxamate [prep. with some ox-*m*-4-xylylide (V) by boiling Me<sub>2</sub>C<sub>2</sub>O<sub>4</sub>], m.p. 77°, gives similarly the 5-NO<sub>2</sub>-, m.p. 145°, and 5:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 169°, both stable to hydrolysis. (V), m.p. 214° (lit. 210°), gives the 5:5'-(NO<sub>2</sub>)<sub>2</sub>-, m.p. 220°, and 5:6:5':6'-(NO<sub>2</sub>)<sub>4</sub>-derivative, amorphous, both stable to hydrolysis. Similarly are obtained acet-*ψ*-cumidide (prep. by Ac<sub>2</sub>O), m.p. 165° (cf. lit.), and its 6-NO<sub>2</sub>- (Me:Me:Me:NH<sub>2</sub>=1:2:4:5), m.p. 198° (cf. lit.), and 3:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 288° (cf. lit.), *Me*, m.p. 115° [6-NO<sub>2</sub>-, m.p. 155°, and 3:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 211°], and Et *ψ*-cumyl-5-carbamate, m.p. 105° [6-NO<sub>2</sub>-, cryst., and 3:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 221°], N-*ψ*-5-cumyl-N'-methyl-, m.p. 212° [6-NO<sub>2</sub>-, m.p. 268°, and N':3:6-(NO<sub>2</sub>)<sub>3</sub>-derivative], and -ethyl-carbamide, m.p. 213° [6-NO<sub>2</sub>-, m.p. 246°, and 3:6:N'-(NO<sub>2</sub>)<sub>3</sub>-derivative], *Me*, m.p. 75° [6-NO<sub>2</sub>-, m.p. 206°, and 3:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 192°], and Et *ψ*-5-cumyloxamate, m.p. 78° [6-NO<sub>2</sub>-, m.p. 162°, and 3:6-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 171°], *s*-ox-*ψ*-5-cumidide, m.p. 237° (lit. 230°) [6:6'-(NO<sub>2</sub>)<sub>2</sub>-derivative, m.p. 317° (block), and 3:6:3':6'-(NO<sub>2</sub>)<sub>4</sub>-derivative, m.p. 340° (block)]. N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O and (I) in EtOH give rapidly *m*-4-xylyloxamhydrazide (VI), m.p. 165° (lit. 160°). 5-*ψ*-Cumyloxamhydrazide (VII), m.p. 212°, is similarly prepared: (VI) in H<sub>2</sub>O containing a little EtOH and (VII) in 50% EtOH, respectively, give substituted *hydrazones* [oxamazones] with the following aldehydes: CH<sub>2</sub>O, m.p. 196°, about 219°, MeCHO, m.p. 205°, 238°, EtCHO, m.p. 186°, 214°, PrCHO, m.p. 168°, 198°, BuCHO, m.p. 173°, 194°, *o*-, m.p. 248°, 252°, and *p*-OH·C<sub>6</sub>H<sub>4</sub>·CHO, m.p. 265°, 267°, *p*-OMe·C<sub>6</sub>H<sub>4</sub>·CHO, m.p. 220°, 245°, vanillin, m.p. 240°, 241°, piperonal, m.p. 261°, 226°, *p*-C<sub>6</sub>H<sub>4</sub>·Me·CHO, m.p. 212°, 245°, *p*-C<sub>6</sub>H<sub>4</sub>·Pr<sup>o</sup>·CHO, m.p. 209°, 205°, *o*-, m.p. 275°.

271°, *m.*, m.p. 211°, 239°, and *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO, 271°, 277°, furfuraldehyde, m.p. 206°, 228° (decomp.), 5-methyl-, m.p. 182°, 180° (decomp.), and 5-hydroxymethyl-furfuraldehyde, m.p. 200°, 174°. R. S. C.

**New diphenylamine derivatives.** J. S. JOFFE, S. D. SUDAKOV, and S. G. KUZNETZOV (J. Gen. Chem. Russ., 1936, 6, 983—987).—3-Chloro-6-nitroaniline-4-sulphonic acid, NH<sub>2</sub>Ph, and MgCO<sub>3</sub> in 60% EtOH (16 hr.; 160—180°) yield the Mg salt of 4-nitro-5-aminodiphenylamine-2-sulphonic acid, from which the internal salt of the corresponding diazonium compound is obtained. This yields a red azo-dye when coupled with β-C<sub>10</sub>H<sub>7</sub>·OH, 4-nitro-5-hydroxydiphenylamine-2-sulphonic acid with boiling H<sub>2</sub>O, and 4-nitro-5-chlorodiphenylamine-2-sulphonic acid by the Sandmeyer reaction. R. T.

**Nitration of benzyaniline and its derivatives.** P. VAN DEN BERG (Rec. trav. chim., 1936, 55, 841—853).—Unless otherwise stated, nitrations given below were effected by abs. HNO<sub>3</sub> and acetylations by Ac<sub>2</sub>O and a little H<sub>2</sub>SO<sub>4</sub> (Ac<sub>2</sub>O alone usually being ineffective). *p*-Nitrobenzyl-2:4:6-trinitrophenylnitroamine (I) [previously considered to be the (NO<sub>2</sub>)<sub>4</sub>-base], m.p. 142° (decomp.), is obtained from *p*'-nitrobenzyl-*p*- and -*o*-nitroaniline, m.p. 140° (cf. lit.) (*Ac* derivative, m.p. 157°), benzyl-2:4-di-, m.p. 116·5°, and -2:4:6-tri-nitroaniline, *p*-nitrobenzyl-2:4-di-, m.p. 186°, and -2:4:6-tri-nitroaniline, m.p. 191°. With NH<sub>3</sub>-EtOH it gives picramide and with hot aq. Na<sub>2</sub>CO<sub>3</sub> picric acid. 2':4'-Dinitrobenzyl-2:4:6-trinitrophenylnitroamine (II), m.p. 151° (decomp.), is obtained from *p*'-nitrobenzyaniline (H<sub>2</sub>SO<sub>4</sub>-HNO<sub>3</sub>, *d* 1·4), benzyl-*p*-nitroaniline, m.p. 147° [*Ac* derivative, m.p. 111° (lit. 108—109°); H<sub>2</sub>SO<sub>4</sub>-abs. HNO<sub>3</sub>], and (I) (H<sub>2</sub>SO<sub>4</sub>-abs. HNO<sub>3</sub>). *o*'-Nitrobenzyl-*p*-, m.p. 202° (*Ac* derivative, m.p. 178°), or -*o*-nitroaniline, m.p. 138° (*Ac* derivative, m.p. 137°), with HNO<sub>3</sub> (*d* 1·46) gives *o*-nitrobenzyl-2:4:6-trinitrophenylnitroamine (III), m.p. 149° (decomp.), and with abs. HNO<sub>3</sub> yields (II). *m*- and *p*-Nitration of the CH<sub>2</sub>Ph of NHPh·CH<sub>2</sub>Ph by a little abs. HNO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub> is confirmed. R. S. C.

**Nitrous acid as a nitrating and oxidising agent.** III. Nitration of 4-dimethylamino-aceto-1-naphthalide, of 4-chloro-1-naphthyldimethylamine, and of β-naphthyldimethylamine. H. H. HODGSON and J. H. CROOK (J.C.S., 1936, 1500—1503).—By coupling α-C<sub>10</sub>H<sub>7</sub>·NMe<sub>2</sub> (*picrate*, m.p. 145°) with diazotised *p*-NH<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·SO<sub>3</sub>H and reductive fission (SnCl<sub>2</sub>-HCl) of the azo-compound is obtained 1:4-NH<sub>2</sub>·C<sub>10</sub>H<sub>6</sub>·NMe<sub>2</sub> [*dihydrochloride* (I)], converted by Ac<sub>2</sub>O into 1:4-NHAc·C<sub>10</sub>H<sub>6</sub>·NMe<sub>2</sub> (II) [*picrate*, m.p. 201° (decomp.)]. (I) is converted (Sandmeyer) into the *hydrochloride*, m.p. 215° (decomp.), of 4-chloro-1-naphthyldimethylamine (III) (*picrate*, m.p. 146°). (II) with NaNO<sub>2</sub>-HCl at 0° is oxidised to α-naphthaquinone, but (III) affords a 2-NO<sub>2</sub>-derivative, (IV), m.p. 58°, synthesised as follows: 2-nitroaceto-1-naphthalide with Cl<sub>2</sub>-AcOH at 100° gives its 2-Cl-derivative, m.p. 219°, hydrolysed to 4-chloro-2-nitro-α-naphthylamine, m.p. 202°, converted (Sandmeyer) into 1:4-dichloro-2-nitronaphthalene, m.p. 116·5° (1-chloro-4-iodo-3-nitronaphthalene, m.p. 107°, is obtained similarly), converted by heat-

ing with NHMe<sub>2</sub>-EtOH into (IV), and by NH<sub>2</sub>Me·HCl-NaOAc-EtOH into 4-chloro-2-nitro-1-naphthyldimethylamine, m.p. 175°. β-C<sub>10</sub>H<sub>7</sub>·NMe<sub>2</sub> [*picrate*, m.p. 200° (decomp.)] and NaNO<sub>2</sub>-HCl at 0° afford 1-nitro-2-naphthyldimethylamine, m.p. 76—77°, synthesised from 2:1-C<sub>10</sub>H<sub>6</sub>Cl·NO<sub>2</sub> and NHMe<sub>2</sub>-EtOH. J. W. B.

**Local anæsthetics containing the ac-tetrahydro-β-naphthylamine pressor group.** H. W. COLES and W. A. LOTT (J. Amer. Chem. Soc., 1936, 58, 1989—1990).—*ac*-Tetrahydro-β-naphthylamine (I) (2 mols.) and CH<sub>2</sub>Cl·CH<sub>2</sub>·OH (1 mol.) in xylene and N<sub>2</sub> at 110—115° give 2-β-hydroxyethylamino-1:2:3:4-tetrahydronaphthalene, which (as *hydrochloride*, m.p. 183·8—184·8°) with the appropriate acyl chloride affords the following *O*-acyl derivative *hydrochlorides*: *Bz*, m.p. 214·9° (corresponding *sulphate*, m.p. 216—218°); *o*-, m.p. 232—233°, *m*-, m.p. 216—217°, and *p*-, m.p. 236·2°, -*nitrobenzoyl* [reduced (Fe, HCl) to the aminobenzoyle derivatives (*dihydrochlorides*, m.p. 150°, 205—206°, and 223·3°, respectively)]; *p*-chloro-, m.p. 219—220°, and *p*-iodo-, m.p. 232°, -*benzoyl*; *cinnamoyl*, m.p. 194—195·8°; *phthaloyl*, m.p. 185—186°. 2-γ-Hydroxypropylamino-1:2:3:4-tetrahydronaphthalene (*hydrochloride*, m.p. 161°), from (I) and CH<sub>2</sub>Cl·CH<sub>2</sub>·CH<sub>2</sub>·OH, similarly affords *Bz*, m.p. 195·6° (corresponding *picrate*, m.p. 83·86°), *m*-, m.p. 173·4—177·4°, and *p*-, m.p. 228—229°, -*nitrobenzoyl*, *p*-chlorobenzoyle, m.p. 188·8—189·8°, *cinnamoyl*, m.p. 204·8—206·8° (decomp.), and β-phenylpropionyl, m.p. 95° (indef.), derivative *hydrochlorides*. All m.p. are corr. Most of the above ester *hydrochlorides* are local anæsthetics but not vasopressors. H. B.

**Reaction of *p*-phenylenediamine and its derivatives with diazonium salts.** J. S. JOFFE and V. J. SOLOVEJTSCHUK (J. Gen. Chem. Russ., 1936, 6, 977—982).—*p*-C<sub>6</sub>H<sub>4</sub>(NHPh)<sub>2</sub> (I) in EtOH-HCl and diazotised metanilic acid at 0° yield 2:5-dianilindiphenyl-3'-sulphonic acid. An analogous reaction takes place when *p*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> or *p*-NHPh·C<sub>6</sub>H<sub>4</sub>·NH·C<sub>6</sub>H<sub>4</sub>·NH<sub>2</sub> is used in place of (I). R. T.

**Preparation of 2:6-dinitro-*p*-phenylenediamine, 2:6-dinitrotetramethyl-*p*-phenylenediamine, and 4-chloro-2:3-dinitroanisole.** H. H. HODGSON and J. H. CROOK (J.C.S., 1936, 1570).—When heated with an excess of NHMe<sub>2</sub>-EtOH, 2:6-dinitrodiphenyl-*p*-anisidine affords 2:6-dinitrotetramethyl-*p*-phenylenediamine, m.p. 176°; 2:6-dinitro-*p*-phenylenediamine is obtained similarly. 4-Chloro-2:3-dinitroanisole, m.p. 133°, is obtained by the Sandmeyer reaction from 2:3-dinitro-*p*-anisidine. J. W. B.

**NN'-Dibenzylethylenediamine.** G. LOB (Rec. trav. chim., 1936, 55, 859—873).—NN'-Dibenzylethylenediamine (I), b.p. 212—213°/12 mm., *d*<sub>4</sub><sup>20</sup> 1·024, *n*<sub>D</sub><sup>20</sup> 1·5624, best obtained by reduction of the Schiff's base with Na-EtOH, gives the following derivatives: *hydrochloride*, m.p. 160—170° (block), *nitrate*, m.p. 180—190° (block), *picrate*, m.p. 200—210° (block), *carbamate* (from 1 mol. of CO<sub>2</sub>), decomp. 90—95° (open tube), *dinitroso*-, m.p. 87°, *Ac*<sub>2</sub>, m.p. 139°, *di-propionyl*, m.p. 69°, *n-butyl*, m.p.

72—73°, -*n*-valeryl, m.p. 91°, -*n*-hexoyl, m.p. 92°, -stearyl, m.p. 67°, -*o*-, m.p. 198—202°, -*m*-, m.p. 136—147°, and -*p*-nitrobenzoyl, m.p. 178°, *Bz*<sub>2</sub> (II), m.p. 183°, *di*-benzenesulphonyl, m.p. 228°; *dicarbonyl*, m.p. 176°, *di*-ethyl-, m.p. 168°, -phenyl-, m.p. 178—179°, -*o*-, m.p. 183—184°, -*m*-, m.p. 171—172°, and -*p*-nitrophenyl-, m.p. 231°, and -2:4-dinitrophenyl-*dicarbonyl*, m.p. 225° (decomp.), *di*-*α*-naphthyl-*dicarbonyl*, m.p. 229° (decomp.), and *diphenyldithiocarbonyl*, m.p. 184°. 2-Phenyl-1:3-dibenzyl-tetrahydroglyoxaline gives (I) and PhCHO with dry or 10% aq. HCl, picric acid, or 10% H<sub>2</sub>SO<sub>4</sub>, but is stable to CO<sub>2</sub>, 10% aq. NaOH, Na-EtOH, or MeI; with KMnO<sub>4</sub> it gives BzOH and NH<sub>2</sub>Bz, with abs. HNO<sub>3</sub> at -10° NN'-*di*-*α*-nitrobenzylethylenediamine, and with I-EtOH N-iodo-NN'-dibenzylethylenediamine diiodide (III), +2EtOH, m.p. 165—166°, and PhCHO. The structure of (III) follows because it contains 2 reactive I (giving with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> N-iodo-NN'-dibenzylethylenediamine, +C<sub>6</sub>H<sub>6</sub>, m.p. 142°), with 10% H<sub>2</sub>SO<sub>4</sub> and subsequent benzoylation affords (II), and is obtained also from (I) and I-Et<sub>2</sub>O. (I) with aliphatic aldehydes alone or with aromatic aldehydes in abs. EtOH gives 2-substituted 1:3-dibenzyltetrahydroglyoxalines in which the 2-substituent is H, m.p. 27°, Me, m.p. 34°, Et, m.p. 32°, Pr<sup>a</sup>, m.p. 11°, Pr<sup>β</sup>, m.p. 33°, Bu, m.p. 13°, amyl, an oil, n<sub>D</sub><sup>20</sup> 1.5448, hexyl, an oil, 1.5406, *p*-tolyl, m.p. 88°, *p*-anisyl, m.p. 90°, *o*-, m.p. 91°, *m*-, m.p. 95—96°, and *p*-nitro-, 101—102°, *o*-, m.p. 96—97°, *m*-, m.p. 93°, and *p*-chloro-, m.p. 110°, *o*-, m.p. 108°, and *p*-hydroxy-, m.p. 139°, *p*-isopropyl-, m.p. 63°, 3-methoxy-4-hydroxy-, m.p. 84—85°, and 3:4-methylenedioxy-phenyl, m.p. 111—112°, benzyl, m.p. 66—67°, furyl, m.p. 74°, 2-5-methyl-, m.p. 77—78°, and 2-5-hydroxymethyl-furyl, m.p. 127°, all hydrolysed by dil HCl. However, (I) does not react with COMe<sub>2</sub> at 200—210°, CMe<sub>2</sub>Cl<sub>2</sub>-K<sub>2</sub>CO<sub>3</sub> at 100°, CPh<sub>2</sub>Cl<sub>2</sub>, or PhI. With COCl<sub>2</sub> (I) gives a *s*-dichloroformyl derivative, m.p. 83°, which decomposes at 230°/12 mm. into CO<sub>2</sub> and 2-keto-1:3-dibenzyltetrahydroglyoxaline, m.p. 93°. With CS<sub>2</sub> (I) gives 2-thio-1:3-dibenzyltetrahydroglyoxaline, m.p. 90°, stable to hot 10% acid or alkali, with (COCl)<sub>2</sub> in C<sub>6</sub>H<sub>6</sub> gives 1:4-dibenzyl-2:3-diketopiperazine, amorphous, m.p. 120—140°, with 2:4-C<sub>6</sub>H<sub>4</sub>Cl(NO<sub>2</sub>)<sub>2</sub> or picryl chloride in NaOAc-EtOH affords NN'-*di*-2:4-di-, m.p. 178°, and -2:4:6-tri-nitrophenyl-NN'-dibenzylethylenediamine, m.p. 202° (decomp. from 190°), respectively, and with CH<sub>2</sub>PhCl-K<sub>2</sub>CO<sub>3</sub> or EtBr-K<sub>2</sub>CO<sub>3</sub> (100°), or C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>-K<sub>2</sub>CO<sub>3</sub> (130—140°) yields NNN'-*tetrabenzyl*-, m.p. 95° [*dihydrochloride*, m.p. 140—150° (block), +*α*-EtOH, m.p. 80—90° (block) (resolidifies and remelts at 140—150°), hydrolysed by cold H<sub>2</sub>O], and NN'-dibenzyl-NN'-*diethyl*-ethylenediamine, b.p. about 250°/20 mm. (*di*-carbonate, -hydrochloride, solid, and -picrate, m.p. 202—206°, and 1:4-dibenzylpiperazine, m.p. 91°, respectively.

R. S. C.

**Diaryls and their derivatives. XII. Selective sorption by vegetable fibres of azo-dyes prepared from dihydroxynaphthalenes and polyhydroxydinaphthyls.** J. S. JOFFE and M. A. TSHIGROV (J. Gen. Chem. Russ., 1936, 6, 1014—1021).—The following azo- and bisazo-dyes, prepared from the appropriate diazonium salts and polyhydroxy-naph-

thalenes and -dinaphthyls, are only very feebly substantive for cotton: 1-*p*-sulphobenzeneazo-2:6- and -2:7-dihydroxynaphthalene, 1-*p*-nitrobenzeneazo-8-*p*-sulphobenzeneazo-2:7-dihydroxynaphthalene, 1-*p*-nitrobenzeneazo-5-*p*-sulphobenzeneazo-2:6-dihydroxynaphthalene, 8-*p*-sulphobenzeneazo-2:7:2':7'-tetrahydroxy-1:1'-dinaphthyl, 5-*p*-sulphobenzeneazo-2:6:2'-tri- and -2:6:2':6'-tetrahydroxy-1:1'-dinaphthyl, and 5-*p*-nitrobenzeneazo-5'-*p*-sulphobenzeneazo-2:6:2'-tri-hydroxy-1:1'-dinaphthyl.

R. T.

**Diazotisation of weakly basic and insoluble amines. Use of pyridine, quinoline, and isoquinoline as solvents for the amines.** C. DEMILT and G. VAN ZANDT (J. Amer. Chem. Soc., 1936, 58, 2044—2046).—3-Nitro-4-aminodiphenyl, 2:6-dichloro-4-nitroaniline, picramide (I), and 3-amino-phenanthrene (II) are completely diazotised by slow addition of a solution in C<sub>5</sub>H<sub>5</sub>N to nitrosylsulphuric acid (III) in H<sub>2</sub>SO<sub>4</sub> at <10°; the mixture is stirred for 30 min. and finally freed from HNO<sub>2</sub> with CO(NH<sub>2</sub>)<sub>2</sub>. 4:6-Dibromo-2-nitroaniline and (I) are similarly diazotised using solutions in quinoline and isoquinoline, respectively. Diazotisation also occurs when (II) (in C<sub>5</sub>H<sub>5</sub>N) and aq. NaNO<sub>2</sub> are added alternately to 40% HBr at <4°. The org. base releases HNO<sub>2</sub> from (III). 2-Nitro-4-phenyl-, m.p. 228°, and 4:6-dibromo-2-nitro-, m.p. 250°, -benzeneazo-β-naphthols are new.

H. B.

**Potentiometric measurements of the transformation of the diazo- into the azo-group.** V. KREFELKA and M. BLABOLIL (Coll. Czech. Chem. Comm., 1936, 8, 408—418).—The tetrazotisation of benzidine (I) can be followed potentiometrically. The coupling at 3° of tetrazotised (I) with Na 8-amino-α-naphthol-3:6-disulphonate (1 mol.), and the coupling of the product with *m*-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub> in Na<sub>2</sub>CO<sub>3</sub> solution were followed by determining, at intervals, the % of diazo-N and azo-N. Diazo-N was measured by boiling an aliquot part with 50% aq. H<sub>2</sub>SO<sub>4</sub> and measuring the evolved N<sub>2</sub>. Azo-N was determined, after removing diazo-N by boiling with H<sub>2</sub>SO<sub>4</sub>, by adding excess of Ti<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> in an atm. of CO<sub>2</sub> and back-titrating electrometrically with approx. 50 c.c. of 0.05N-FeNH<sub>4</sub>(SO<sub>4</sub>)<sub>6</sub>. The first coupling is rapid at first, but requires >40 hr. for completion. The acidity of the medium has little effect. The second coupling is complete in 2 hr. Tetrazotised (I) is stable at 3° whether in acid, neutral, or alkaline (Na<sub>2</sub>CO<sub>3</sub>) solution.

J. G. A. G.

**Manufacture of alkylated phenols.**—See B., 1936, 1083.

**Action of hexamethylenetetramine on alkyl halides in presence of monohydric phenols.** I. P. BOUCHEREAU (J. Pharm. Chim., 1936, [viii], 24, 352—362).—By heating (CH<sub>2</sub>)<sub>6</sub>N<sub>4</sub> (I) with RX and ArOH in CHCl<sub>3</sub> or EtOH are obtained cryst. compounds of the general type (CH<sub>2</sub>)<sub>6</sub>N<sub>4</sub>(RX)(ArOH) in which the halogen remains united to the alkyl. When heated the halogen migrates to the phenol to give halogenated phenol-CH<sub>2</sub>O resins. Thus are obtained the compounds from (I), PhOH, and : EtBr, loses NH<sub>3</sub> at 85—90°, resinifies at 130—150°; CH<sub>2</sub>PhCl, m.p. 79—80°; EtI, m.p. 118—120°,

resinifies at 140—150°; and (I),  $p\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$ , and  $\text{EtBr}$ , m.p. 85°, resinifies at 130—140°. These compounds are antiseptic and non-toxic when injected intravenously and their therapeutic uses are briefly described.

J. W. B.

**Mills Nixon effect.** L. F. FIESER and W. C. LOTHROP (J. Amer. Chem. Soc., 1936, 58, 2050—2054).—The coupling of 5-hydroxy-4:7-dimethylhydrindene and the non-coupling of 5-hydroxy-6-methylhydrindene with diazotised  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$  indicate, in agreement with Mills and Nixon (A., 1931, 83), that hydrindene has the rigid structure (I). Contrary to these authors,

1:2:3:4-tetrahydronaphthalene can react in both Kekulé forms, since its 6-hydroxy-5:8-dimethyl derivative undergoes coupling (cf. this vol., 835).

$\beta$ -3-Amino-4-methylphenylpropionic acid, m.p. 140—141° [obtained by reduction ( $\text{H}_2$ ,  $\text{PtO}_2$ , 95%  $\text{EtOH}$ ) of 3-nitro-4-methylcinnamic acid], is converted (diazo-method) into the 3-OH-acid, m.p. 156—157°, methylated ( $\text{Me}_2\text{SO}_4$ ) to  $\beta$ -3-methoxy-4-methylphenylpropionic acid, m.p. 82—83°. The chloride of this with  $\text{AlCl}_3$  in  $\text{CS}_2$  gives 5-methoxy-6-methyl-1-hydrindone, m.p. 114—115° [attempted demethylation (48%  $\text{HBr}$ ,  $\text{AcOH}$ ) gave a dimeride,  $\text{C}_{22}\text{H}_{24}\text{O}_4$ , m.p. 237—240°], which when reduced (modified Clemmensen) and then demethylated (48%  $\text{HBr}$ +45%  $\text{HI}$  in  $\text{AcOH}$  and  $\text{N}_2$ ) affords 5-hydroxy-6-methylhydrindene, m.p. 83—84° (Bz derivative, m.p. 111—112°). 4:7-Dimethyl-1-hydrindone (Mayer and Müller, A., 1928, 65) is reduced (Clemmensen) to 4:7-dimethylhydrindene, b.p. 223—225°, m.p. —1.5° [5:6-( $\text{NO}_2$ )<sub>2</sub>-derivative, m.p. 191—192°], which with conc.  $\text{H}_2\text{SO}_4$  at 100° (bath) gives the 5-sulphonic acid [ $p$ -toluidine salt, m.p. 248—249° (decomp.)] ( $\text{KOH}$ -fusion of the Na salt gives tars). Methoxy- $p$ -xylene added to  $\text{CH}_2\text{Cl}\cdot\text{CH}_2\cdot\text{COCl}$  and  $\text{AlCl}_3$  in cold  $\text{CS}_2$  affords 2-methoxy-5- $\beta$ -chloropropionyl- $p$ -xylene, m.p. 85—86°, converted by  $\text{NHPh}\cdot\text{NH}$ , in  $\text{EtOH}$  into 1-phenyl-3-3'-methoxy-2':5'-dimethylphenyl- $\Delta^2$ -pyrazoline, m.p. 171—172°, and by  $\text{AcOH}$ -conc.  $\text{H}_2\text{SO}_4$  at 100° (bath) into 5-methoxy-4:7-dimethyl-1-hydrindone, m.p. 163—165°. This is reduced (Clemmensen) to the hydrindene, m.p. 25—26°, demethylated (48%  $\text{HBr}$  in  $\text{AcOH}$  and  $\text{N}_2$ ) to 5-hydroxy-4:7-dimethylhydrindene, m.p. 111—112° [Bz, m.p. 72—73°, and 6- $p$ -nitrobenzeneazo-, m.p. 220—222° (decomp.), derivatives].

1-Keto-7-methoxy-5:8-dimethyl-1:2:3:4-tetrahydronaphthalene (improved prep.; cf. Clemons *et al.*, A., 1929, 1454) is reduced (Clemmensen) to 6-methoxy-, m.p. 38—39°, which is demethylated (45%  $\text{HI}$ ,  $\text{AcOH}$ ) to 6-hydroxy-5:8-dimethyl-1:2:3:4-tetrahydronaphthalene, m.p. 104—105° (Bz, m.p. 119—120°, and 7- $p$ -nitrobenzeneazo-, m.p. 229—231°, derivatives).

H. B.

**Synthesis of 6:7-methylenedioxy-1:1-dimethyl-1:2:3:4-tetrahydronaphthalene.** R. M. ORCUTT and M. T. BOGERT (J. Amer. Chem. Soc., 1936, 58, 2055—2056).—The Et ester, b.p. 184—185°/14 mm., of piperonylacetic acid, m.p. 87—90° (lit. 84°) [prepared by reduction ( $\text{Na-Hg}$ ) of piperonylideneacetic acid (I)], is reduced ( $\text{Na}$ ,  $\text{Bu}^\text{t}\text{OH}$ ) to

$\beta$ -piperonyl ethyl alcohol (II), b.p. 170—172°/8 mm., 184—186°/16 mm. (lit. 149—150°/6 mm.), m.p. 28—29° (phenylcarbamate, m.p. 98—99°), also obtained by reduction ( $\text{Na}$  powder,  $\text{Bu}^\text{t}\text{OH}$ ,  $\text{PhMe}$ ) of the Et ester of (I). (II) and  $\text{PBr}_3$  at  $\approx$  about 28° give the bromide, b.p. 163—165°/7.5 mm., the Grignard reagent from which with  $\text{COMe}_2$  gives  $\delta$ -piperonyl- $\beta$ -methylbutan- $\beta$ -ol (III), b.p. 145—148°/2 mm., and  $\alpha\delta$ -dipiperonylbutane, m.p. 78°. (III) is converted by 85%  $\text{H}_2\text{SO}_4$  at  $\approx$  10° into 6:7-methylenedioxy-1:1-dimethyl-1:2:3:4-tetrahydronaphthalene, b.p. 148—149°/10 mm., dehydrogenated (S) to 6:7-methylenedioxy-1-methylnaphthalene (picrate, m.p. 134—136°).

H. B.

**Synthesis of 5:6-methylenedioxy-1:1:2-trimethylindane from safrole.** R. M. ORCUTT and M. T. BOGERT (J. Amer. Chem. Soc., 1936, 58, 2057—2059; cf. A., 1934, 292).—Safole and 69%  $\text{HBr}$  at about 0° give 75% of  $\alpha$ -bromo- $\alpha$ -piperonyl ethane [ $\beta$ -bromo- $\alpha$ -3:4-methylenedioxyphenylpropane], b.p. 145°/9 mm., the Grignard reagent (I) from which reacts readily with atm.  $\text{O}_2$ . Hydrolysis ( $\text{H}_2\text{O}$ ) of (I) affords  $\alpha$ -piperonyl ethyl alcohol (II), b.p. 127—129°/3 mm. (phenylcarbamate, m.p. 93—94°), and some  $\beta$ - $\gamma$ -dipiperonylbutane (III), m.p. 74°. (I) and  $\text{COMe}_2$  in  $\text{N}_2$  give (III) and  $\gamma$ -piperonyl- $\beta$ -methylbutan- $\beta$ -ol (IV), b.p. 142—144°/3 mm., m.p. 49° (softens at 43°); in presence of air (II) (main product), (III), and (IV) result. (IV) is converted by cold 85%  $\text{H}_2\text{SO}_4$  into 5:6-methylenedioxy-1:1:2-trimethylindane (V), b.p. 137°/11 mm., and (occasionally) some  $\gamma$ -piperonyl- $\beta$ -methyl- $\Delta^2$ -butene, b.p. 120°/7 mm., which with  $\text{H}_2\text{SO}_4$  also gives (V). *iso*Safole and 69%  $\text{HBr}$  at 0° afford the unstable  $\alpha$ -bromo- $\alpha$ -3:4-methylenedioxyphenylpropane, decomp. on attempted distillation at 2 mm. 3:4-Methylenedioxyphenylethylcarbinol, b.p. 126—127°/3 mm. (cf. Mameli, A., 1904, i, 1023) (from piperonal and  $\text{MgEtBr}$ ), could not be converted into the bromide ( $\text{PBr}_3$ ); when kept it gives the carbinyl ether, m.p. 85° (lit. 88°).

H. B.

**Diaryls and their derivatives. IX. Sulphonation.** J. S. JOFFE, S. G. KUZNETZOV, and A. A. PANOV. X. Nitration of 2:2'-dihydroxy-1:1'-dinaphthyl. J. S. JOFFE (J. Gen. Chem. Russ., 1936, 6, 999—1002, 1003—1005).—IX. Sulphonation of 2:2'-dihydroxy-1:1'-dinaphthyl (I) at 100° yields the 6-mono- and the 6:6'-di-sulphonic acids. The former, when fused with  $\text{NaOH}$ , affords 2:6:2'-trihydroxy-1:1'-dinaphthyl, m.p. 305—307°, giving a red azo-dye, m.p. 138—140°, when coupled with  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\text{Cl}$ .

X. (I) and  $\text{HNO}_3$  in  $\text{AcOH}$  at 100° yield 6:6'-dinitro-2:2'-dihydroxy-1:1'-dinaphthyl, m.p.  $>300^\circ$  (decomp.), reduced by  $\text{NaHSO}_3$  to the 6:6'-( $\text{NH}_2$ )<sub>2</sub>-compound, m.p.  $>300^\circ$ . This is readily converted by  $\text{HNO}_2$  into the bisdazo-compound [compound with 2:3:6-OH $\cdot\text{C}_{10}\text{H}_5(\text{SO}_3\text{H})_2$ ].

R. T.

**Alkylphenols. I. 4-n-Alkylpyrogallols.** M. C. HART and E. H. WOODRUFF (J. Amer. Chem. Soc., 1936, 58, 1957—1959).—1:2:3- $\text{C}_6\text{H}_3(\text{OH})_3$ , the appropriate  $\text{AlkCO}_2\text{H}$ , and  $\text{ZnCl}_2$  at 130—140° give 2:3:4-trihydroxyphenyl Me, m.p. 170°, Et, m.p. 128—129°,  $\text{Pr}^\text{a}$ , m.p. 101—102°,  $\text{Bu}^\text{a}$ , m.p. 84—84.5°, *n*-amyl, m.p. 86.5—87°, and *n*-hexyl, m.p.

78—78.5°, *ketones*, reduced (Clemmensen) to 4-ethyl-, m.p. 108.5° (1, 2:3), 4-*n*-propyl-, m.p. 110—111° (2:5, 4:4), 4-*n*-butyl-, m.p. 88—89° (5, 12:6), 4-*n*-amyl-, m.p. 90—91° (19, 25), 4-*n*-hexyl-, m.p. 104—105° (44, 38), and 4-*n*-heptyl-pyrogallol, m.p. 116—117° (50, 26), respectively. The nos. in parentheses are the PhOH-coeffs. towards *S. aureus* and *B. coli*, respectively. The alkylpyrogallols, which show quasi-specificity (cf. Klarman *et al.*, A., 1933, 817), are less effective germicides than alkyl-phenols and -resorcinols. H. B.

**Molecular rearrangement of N-sulphenanilides in alkaline solution.** IV. M. L. MOORE and T. B. JOHNSON (J. Amer. Chem. Soc., 1936, 58, 1960—1961; cf. this vol., 200).—4-Chloro-2-nitrobenzenesulphenanilide, -*o*-toluidide, and -*o*-chloroanilide, m.p. 112° (from 2:4-NO<sub>2</sub>·C<sub>6</sub>H<sub>3</sub>Cl·SCl and *o*-C<sub>6</sub>H<sub>4</sub>Cl·NH<sub>2</sub>), and *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·S·NH·C<sub>6</sub>H<sub>4</sub>Cl-*o* rearrange when heated with aq. EtOH-NaOH and give 4'-chloro-2'-nitro-2-thiol-, a chloronitrothiolmethyl-, a dichloronitrothiol-, and a chloronitrothiol-diphenylamine (as Na salts; *S*-Me ethers, m.p. 135—136°, 164—165°, 158—158.5°, and 144.5—145°, respectively), respectively. The formation of thiodiphenylamines is not observed (cf. Moore and Smiles, A., 1935, 1511). *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·S·NHAr (Ar=Ph, *o*-C<sub>6</sub>H<sub>4</sub>Me, and *o*-C<sub>6</sub>H<sub>4</sub>Cl) do not similarly rearrange. H. B.

**Molecular transformations in the cyclane series.** M. TIEFFENAU (Bull. Soc. chim., 1936, [v], 3, 1942—1974).—A lecture.

**Reduction of acid chlorides and anhydrides by chromous hydroxide.** R. GRAF [with M. TATZEL] (J. pr. Chem., 1936, [ii], 146, 198—200).—Simultaneous addition of BzCl and 50% KOH to an aq. suspension of Cr(OAc)<sub>2</sub> at 0° gives >30% yield of CH<sub>2</sub>Ph·OH, also obtained from Bz<sub>2</sub>O. H. W.

**Preparation of amino-alcohols.** II. J. T. ABRAMS and F. S. KIPPING (J.C.S., 1936, 1480—1481).—Condensation of CH<sub>2</sub>Bz·CO<sub>2</sub>Et-NaOEt-EtOH with the appropriate alkyl iodide affords *Et* α-benzoyl-*isovalerate* (*amide*, m.p. 179—180°), -γ-methylvalerate [*amide* (I), m.p. 157—158°, and -δ-methyl-*n*-hexoate, b.p. 169—170°/6 mm. [*amide* (II), m.p. 156—157°]. Reduction of (I) with Al-Hg-aq. EtOH affords α-hydroxybenzyl-γ-methylvaleramide, m.p. 136—137°, and the *pinacol*, [NH<sub>2</sub>·CO·CHBu<sup>δ</sup>·CPh(OH)]<sub>2</sub>, m.p. 169°, separated by fractional crystallisation from EtOAc-C<sub>6</sub>H<sub>6</sub>. Similar reduction of (II) affords α-hydroxybenzyl-δ-methylhexoamide, m.p. 137—138°, together with the *pinacol*, m.p. 159° (not analysed). α-Hydroxybenzylbutyramide (A., 1935, 209) with Br-aq. NaOH affords β-amino-α-phenylbutyl alcohol, m.p. 79—80° (*hydrochloride*, m.p. 195—196°), probably a diastereoisomeride of the base obtained by Hartung *et al.* (A., 1930, 1286). J. W. B.

**Phenanthrene series.** XIII. 9:10-Dihydrophenanthrene and amino-alcohols derived from it. A. BURGER and E. MOSETTIG (J. Amer. Chem. Soc., 1936, 58, 1857—1860).—Phenanthrene is reduced [H<sub>2</sub> (136—218 atm.), Cu-Cr-Ba oxide, EtOH, 220°] to the 9:10-H<sub>2</sub>-derivative (I) (80% yield); anthracene is similarly reduced more quickly at 160°. (I) and AcCl (1.2 mols.) with AlCl<sub>3</sub> (2 mols.) in cold

PhNO<sub>2</sub> give 2-acetyl-9:10-dihydrophenanthrene (II) [(I) thus reacts as a diphenyl], which is oxidised by CrO<sub>3</sub>-aq. AcOH to 2-acetyl-9:10-phenanthraquinone, and by dil. NaOCl to an acid, the Me ester of which with Se at 280—300° affords phenanthrene-2-carboxylic acid. (I) and EtCOCl similarly yield 2-propionyl-9:10-dihydrophenanthrene (III), m.p. 62—63° (*semicarbazone*, m.p. 213—214°), oxidised (CrO<sub>3</sub>) to 2-propionyl-9:10-phenanthraquinone, m.p. 215—217° (decomp.). 2-Bromoacetyl-9:10-dihydrophenanthrene [from (II) and Br in Et<sub>2</sub>O; the 2-chloroacetyl derivative, m.p. 100—101°, is obtained in poor yield by the Friedel-Crafts reaction] and the appropriate NHR, in C<sub>6</sub>H<sub>6</sub> give 2-dimethylamino- [*hydrochloride*, m.p. 213—215° (decomp.)], 2-diethylamino- [*hydrochloride*, m.p. 173—176° (decomp.)], 2-piperidino-, m.p. 86—87° [*hydrochloride*, m.p. 240—252° (decomp.)], and 2-1':2':3':4'-tetrahydroisoquinolino- (IV) [*hydrochloride*, m.p. 238—239° (decomp.)], -acetyl-9:10-dihydrophenanthrenes, which are reduced (H<sub>2</sub>, PtO<sub>2</sub>, 90% EtOH or MeOH, using salts) to 2-β-dimethylamino-α-hydroxy- [*hydrochloride*, m.p. 170—172° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 216—217° (decomp.)], 2-β-diethylamino-α-hydroxy- [*hydrochloride*, m.p. 184—186° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 145—150° (decomp.)], 2-β-piperidino-α-hydroxy-, m.p. 124° [*hydrochloride*, m.p. 242° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 212—213° (decomp.)], and 2-β-1':2':3':4'-tetrahydroisoquinolino-α-hydroxy-, m.p. 101—102° [*hydrochloride*, m.p. 244—246° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 197—199° (decomp.)], -ethyl-9:10-dihydrophenanthrene, respectively. 2-α-Bromopropionyl-9:10-dihydrophenanthrene, m.p. 85—86° [from (III) and Br in Et<sub>2</sub>O], similarly gives 2-α-dimethylamino- [*hydrochloride*, m.p. 210—214° (decomp.)], 2-α-diethylamino- (*perchlorate*, m.p. 138—140°), 2-α-piperidino- [*hydrochloride*, m.p. 208—213° (decomp.)], and 2-α-1':2':3':4'-tetrahydroisoquinolino- (*perchlorate*, m.p. 230—231°), -propionyl-9:10-dihydrophenanthrenes, reduced to 2-β-dimethylamino-α-hydroxy-, m.p. 90—91° [*hydrochloride*, m.p. 225—227° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 210—211° (decomp.)], 2-β-diethylamino-α-hydroxy- [*hydrochloride*, m.p. 209—210° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 189—190° (decomp.)], 2-β-piperidino-α-hydroxy-, m.p. 104—106° [*hydrochloride*, m.p. 249—250° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 192—194° (decomp.)], and 2-β-1':2':3':4'-tetrahydroisoquinolino-α-hydroxy-, m.p. 136—138° [*hydrochloride*, m.p. 226—228° (decomp.)], *O*-Ac derivative *hydrochloride*, m.p. 190—192° (decomp.)], -propyl-9:10-dihydrophenanthrene, respectively. (IV) is accompanied by resinous material which with dil. alkali gives 9:10-dihydrophenanthrene-2-carboxylic acid. H. B.

**Lignin.** XII. Action of hydrogen sulphite solutions on aromatic alcohols. S. HEDEN and B. HOLMBERG (Svensk Kem. Tidskr., 1936, 48, 207—211).—Many aromatic alcohols resemble lignin in that when boiled with NaHSO<sub>3</sub>, OH is replaced by SO<sub>3</sub>H. M. H. M. A.

**Synthesis of *p*-methoxybenzyl alcohol.** R. QUELET and J. ALLARD (Bull. Soc. chim., 1936, [v],

3, 1794—1800).—Previous work (A., 1934, 290) is repeated in the light of that of Ofner (A., 1935, 1120), which is confirmed. *p*-(with *o*-) $\text{CH}_2\text{Cl}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$ , obtained as before (method improved), is converted into *p*-(with *o*-) $\text{OAc}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$  (I). Hydrolysis (aq. KOH) then gives *p*- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{OH}$  and (*p*- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2$ ) $_2\text{O}$ , which decomposes on distillation, giving *p*- $\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{OMe}$  and *p*- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ . Hydrolysis of (I) by KOH-EtOH yields 90% of *p*- and 10% of *o*- $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{OH}$ . E. W. W.

**Derivatives of phenyldihydroxypropylamine.** H. OHLE and G. HAESELER (Ber., 1936, 69, [B], 2324—2327; cf. this vol., 1491).—Epichlorohydrin and *p*- $\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{SO}_2\cdot\text{NHPh}$  in presence of a little  $\text{C}_5\text{H}_5\text{N}$  at 120—150° give *p*-toluenesulphonphenyl- $\gamma$ -chloro- $\beta$ -hydroxypropylamine  $\text{C}_6\text{H}_4\cdot\text{Me}\cdot\text{SO}_2\cdot\text{NPh}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\text{Cl}$ , m.p. 96—97°, transformed by cautious addition of NaOH to its solution in EtOH at 100° into *p*-toluenesulphonphenyl- $\beta$ - $\gamma$ -oxidopropylamine (I), m.p. 77°, in 92% yield. Addition of a drop of  $\text{C}_5\text{H}_5\text{N}$  to (I) and BzOH at 120° affords *p*-toluenesulphonphenyl- $\beta$ -hydroxy- $\gamma$ -benzoyloxypropylamine, m.p. 117—118°, transformed by BzCl in  $\text{C}_5\text{H}_5\text{N}$  into *p*-toluenesulphonphenyl- $\beta$ - $\gamma$ -dibenzoyloxypropylamine (II), m.p. 135—136°. (II) and HBr-AcOH yield 2:4-dibromophenyl- $\beta$ - $\gamma$ -dibenzoyloxypropylamine (III) m.p. 122-5°, and ( $\text{C}_6\text{H}_4\cdot\text{Me}$ ) $_2\text{S}_2$  (III) (hydrobromide, m.p. 176—178°) gives a non-cryst. nitroscamine and N-Ac derivative. It is hydrolysed and then oxidised by  $\text{KMnO}_4$  in  $\text{COMe}_2$  to 2:4- $\text{C}_6\text{H}_3\text{Br}_2\cdot\text{NH}_2$  and 2:4-dibromo-oxanilic acid. H. W.

**Isomeride of lutein from furze (*Ulex europaeus*).**—See this vol., 1571.

**Sterol group. XXVII. Oxidation of cholesterol hydrogen phthalate with potassium permanganate:**  $\beta$ -7-hydroxycholesterol and tetrahydrocholestane. T. BARR, I. M. HEILBRON, E. G. PARRY, and F. S. SPRING (J.C.S., 1936, 1437—1440).—Cholesteryl H phthalate with 0.25N- $\text{KMnO}_4$ -N- $\text{Na}_2\text{CO}_3$  at room temp. affords the following three products: the H phthalate, m.p. 199—201° (insol. in  $\text{CHCl}_3$ - $\text{Et}_2\text{O}$ ), of  $\beta$ -7-hydroxycholesterol, m.p. 184—185°,  $[\alpha]_D^{25}$  -86.4° [ $\text{Ac}_2$ , m.p. 121—122°,  $[\alpha]_D^{25}$  -174.6°, and  $\text{Bz}_2$  (I), m.p. 150—151°,  $[\alpha]_D^{25}$  -105.3°, derivatives; oxide, m.p. 173—175° ( $\text{Ac}_2$  derivative, m.p. 203—204°)], which is a stereoisomeride of the (now designated)  $\alpha$ -7-hydroxycholesterol of Windaus *et al.* (A., 1935, 1363) since thermal decomp. of (I) affords 7-dehydrocholesteryl benzoate; from the  $\text{CHCl}_3$ - $\text{Et}_2\text{O}$  extract is obtained the H phthalate, m.p. 236—237°, of 3:5:6:7- or 3:4:5:6-tetrahydrocholestane, + $\text{H}_2\text{O}$ , m.p. 235—236°, and anhyd., m.p. 230—231° ( $\text{Ac}_3$ , m.p. 219—220°,  $[\alpha]_D^{25}$  +23.1°, and  $\text{Bz}_3$ , m.p. 271—272°,  $[\alpha]_D^{25}$  +114.0°, derivatives), whilst KOH-EtOH hydrolysis of the resin from the  $\text{CHCl}_3$ - $\text{Et}_2\text{O}$  mother-liquor affords the hydroxyketo-acid  $\text{C}_{27}\text{H}_{46}\text{O}_4$  obtained by oxidation of cholesteryl acetate with  $\text{CrO}_3$  (Windaus *et al.*, A., 1915, i, 677), identified by thermal decomp. to the diene,  $\text{C}_{26}\text{H}_{42}$ , m.p. 76° (Lettré, A., 1933, 1047). All  $[\alpha]_D$  vals. are in  $\text{CHCl}_3$ . J. W. B.

**Enolisation of oxycholesterilene.** V. A. PETROW (Nature, 1936, 138, 645).—Acetylation of 7-ketocholesterol removes the  $\text{C}_{63}\cdot\text{OH}$ , yielding oxycholesterilene and its acetate, m.p. 90—92°,  $[\alpha]_D$  -222°,  $[\alpha]_{5461}$  -283°, which has the appended structure.

L. S. T.

**Lanosterol.** I. C. DORÉE and V. A. PETROW (J.C.S., 1936, 1562—1567).—Dehydrogenation of lanosterol (I) with Pd-C at 330—360° affords an oily hydrocarbon,  $\text{C}_{18}\text{H}_{20}$  [ $\text{C}_6\text{H}_3(\text{NO}_3)_3$  adduct, m.p. 147—148°]. The presence of one reactive and one unreactive double linking in (I) is proved by the following data: titration with  $\text{BzO}_2\text{H}$  gives an  $\text{O}_2$  absorption never >1.5 atoms, but lanosteryl acetate (II) with  $\text{BzO}_2\text{H}\cdot\text{CHCl}_3$  at 0° affords its oxide, m.p. 178°, hydrolysed to lanosterol oxide, m.p. 139—140°. (II) with  $\text{H}_2\text{O}_2$ -AcOH and subsequent hydrolysis gives oxylanostanetriol, m.p. 120—121° ( $\text{Ac}_1$  derivative, m.p. 162—163°). The ultra-violet absorption spectrum shows that lanostenone (III) (improved prep.) is not an  $\alpha\beta$ -unsaturated ketone, and with  $\text{NHPh}\cdot\text{NH}_2$ -AcOH it gives a tetrahydrocarbazole derivative, m.p. 201—202° (picrate, m.p. 201°), which surface film measurements suggest must be an *ang*-derivative. The monohydrochloride of (II), m.p. 126—127°, is hydrolysed by KOH-EtOH to isolanosterol (IV), m.p. 131—132° ( $\text{Ac}$  derivative, m.p. 130—131°), oxidised to isolanostenone (V), m.p. 138—139° (tetrahydrocarbazole derivative, m.p. 224—225°), the semicarbazone, m.p. 210°, of which is reduced by Na-EtOH at 180° to isolanostene, m.p. 80—81°; lanostene, similarly prepared, has m.p. 76—77°. (V) with Na-boiling EtOH gives isolanosterol-A, m.p. 130—131° ( $\text{Ac}$  derivative, m.p. 138°), which depresses the m.p. of (IV). Attempted oxidation of (II) with  $\text{CrO}_3$ -66% AcOH affords the *Ac* derivative, m.p. 164°, of lanosterol-D, m.p. 137—138°, which is obtained on hydrolysis, and is a OH-spatial isomeride of (I) since it is oxidised to (III). Surface film measurements of the above derivatives are recorded and support the conclusion that (I) has an amyrin type of structure. J. W. B.

**Artificial production of oestrogenic substances from sterols. I. Synthesis of the oestrogenic substance from animal sterols.** I. REMESOV and N. TAVASTSTJERNA. II. Synthesis of an isomeride of the follicular hormone from vegetable sterols. I. REMESOV (Rec. trav. chim., 1936, 55, 791—797, 797—803).—I. Agnosterol (modified prep.),  $\text{C}_{30}\text{H}_{47}\cdot\text{OH}$  (acetate), contains 3 ethylenic linkings ( $\text{BzO}_2\text{H}$ ), resists complete hydrogenation, and resembles theelin in absorption spectrum. A mixture with  $\text{CH}_2\text{Br}\cdot\text{CO}_2\text{Na}$ , when heated with Br- $\text{Ac}_2\text{O}$ , gives the crude acetate dibromide, m.p. 130—131°,  $[\alpha]_D^{25}$  -79° in  $\text{CHCl}_3$ , which with maleic anhydride in  $\text{C}_6\text{H}_6$  at 133—135° affords the adduct, m.p. (crude) 196—204°; oxidation by  $\text{CrO}_3$  and subsequent debromination gives gums, but the final product shows oestrogenic activity by the Allen-Doisy test and towards monkeys.

II. Neorgosterol (prep. in 22–26% yield from ergosterol), m.p. 152.5°, gives the *acetate dibromide*,

m.p. 180–181°, which with  $O_3$  in AcOH affords  $CHMePr^{\beta}\cdot CHO$  and the *acid* (I), m.p. 210–212°, the *Me* ester, m.p. 144–145°, of which by the  $MgPhBr$  method is degraded to a *substance*,  $C_{13}H_{22}O_2$ , m.p. 225–226°, sublimes at 210°/0.001 mm., believed to have structure (II) and to be isomeric with the follicular hormone. 1 g. of (II) corresponds with  $8\text{--}10 \times 10^6$  mouse units of theelin. R. S. C.

**Sterols. VII. *cis*- and *trans*-Androstanone-3-carboxylic acid**, an oestrus-producing male hormone derivative, and *epicholesterol*. R. E. MARKER, O. KAMM, T. S. OAKWOOD, and J. F. LAUCIUS (J. Amer. Chem. Soc., 1936, 58, 1948–1950).—Oxidation ( $CrO_3$ , AcOH) of *Me* (*cis*+*trans*)-cholestane-3-carboxylate (this vol., 604) gives a little *Me* (*cis*+*trans*)-androstanone-3-carboxylate [purified through the semicarbazone, m.p. 250–260° (decomp.)], hydrolysed (MeOH-KOH) to the (*cis*+*trans*)-*acid*, m.p. 253°, which is readily esterified;  $5\text{--}10 \times 10^6$  g. of the *Et* ester, m.p. 108–110°, which is more active than the acid, causes an oestrus response in rats but is inactive in the cock's comb test. Unsaturation is not necessary for oestrus production. *epiCholesterol* (I) is separated from cholesterol (cf. *loc. cit.*) by purification of the mixture through the H succinates, fractional crystallisation of the mixed acetates from EtOH, hydrolysis (EtOH-NaOH) of the more sol. material, and final fractionation of the mixed benzoates [containing about 90% of that of (I)]. The acetate of (I) and Br in Et<sub>2</sub>O-AcOH give a *tetra-bromocholestane*, m.p. 110°, which differs from that obtained from cholesterylene (II) and Br. (I) is dehydrated by EtOH-HCl to (II). Ultra-violet irradiation of (I) does not give antirachitic products.

H. B.

**2:4-Dimethylphenylacetic [*m*-4-xylylacetic] acid and its derivatives.** J. V. HARISPE (Ann. Chim., 1936, [xi], 6, 249–347).—Re-examination of the conversion of pinonic acid (I) into *m*-4-xylylacetic acid (II) (Barbier and Grignard, A., 1909, i, 301) by  $Br\text{--}H_2O$  shows that in the first phase, the duration of which is a function of the homogeneity of the medium, H attached to C probably vicinal to CO is replaced by Br. Substitution causes production of HBr, under the influence of which (or of HCl added before commencement of the change) the bromopinonic acid becomes isomerised to the compound  $CHBrAc\cdot CH_2\cdot CH\begin{smallmatrix} CMe_2\cdot O \\ | \\ CH-CO \end{smallmatrix}$  (III), which slowly in the cold, but very rapidly when heated, loses HBr with formation of an ethylenic linking, eliminates 1 mol. of  $H_2O$  between CO and a terminal Me with production of a second ethylenic linking and of a six-membered ring, and suffers hydrolysis of the lactonic function immediately followed by dehydra-

tion of the corresponding *tert*-alcohol with appearance of the third ethylenic linking, and hence of the benzenoid nucleus. The yield of (II) is >70%; the remaining 30% is a brownish-red resin containing esterifiable  $CO_2H$ . The heats of combustion of (I), (II), and (III) have been determined. (II) has m.p. 105.5–106° (block), b.p. 300–302°(corr.)/760 mm. Its physiological properties are described. The *K* (+ $H_2O$ ), *Ba* (+ $H_2O$ ), *Ca* (+4.5 $H_2O$ ), m.p. 120°, *Ag* (+ $H_2O$ ), m.p. <100°, and *Na* (+1 $H_2O$ ) salts have been prepared. (II) gives the following esters; *Me*, b.p. 138°(corr.)/20 mm.; *Et*, b.p. 146.5°(corr.)/18 mm.; *Pr*<sup>a</sup>, b.p. 155°(corr.)/18 mm.; *Bu*<sup>a</sup>, b.p. 164°(corr.)/17 mm.; *CH<sub>2</sub>Ph*, b.p. 214°(corr.)/20 mm. *m*-4-*Xylylacetyl chloride* (IV), b.p. 116°(corr.)/11 mm., from (II) and  $SOCl_2$ , is converted in the usual manner into the corresponding amide, m.p. 184° (block), *anilide*, m.p. 144.5° (block), *o-toluidide*, m.p. 172° (block), *p-toluidide*, m.p. 145° (block), 1-, m.p. 209°, and 2-, m.p. 183°, *naphthylamide*, and by  $C_6H_5Me_2\cdot CH_2\cdot CO_2Ag$  into *m*-4-*xylylacetic anhydride*, m.p. 86–87°. *Ph m*-4-*xylylacetate*, m.p. 39°, is derived from (IV),  $PhOH$ , and  $K_2CO_3$  in boiling  $C_6H_6$ . (IV) and  $C_6H_6$  in presence of  $AlCl_3$  afford 2:4-*dimethyldeoxybenzoin*, m.p. 108.5° (block) (*oxime*, m.p. 114.5°). From the esters by means of the appropriate Grignard reagents the following *carbinols* are obtained: 2:4-*dimethylbenzyl-dimethyl*-, b.p. 139°(corr.)/20 mm.; *diethyl*-, b.p. 162°(corr.)/18 mm.; *di-n-propyl*-, b.p. 179°(corr.)/19 mm.; *di-n-butyl*-, b.p. 203°(corr.)/24 mm.; *diphenyl*-, m.p. 99° (block); *dibenzyl*-, m.p. 87–88° (block). Dehydration of the *tert*-alcohols is effected with  $Ac_2O + AcCl$ ,  $Ac_2O + H_2SO_4$ , or by  $H_2SO_4$  giving the unsaturated hydrocarbon which is oxidised by  $CrO_3$  in AcOH at 100° or by alkaline  $KMnO_4$  at room temp. to 2:4- $C_6H_5Me_2\cdot CO_2H$  and the corresponding ketone.  $\alpha$ -*m*-4-*Xylyl*- $\beta$ -*methyl*- $\Delta^{\alpha}$ -*propene* has b.p. about 108–109°(corr.)/16 mm.;  $\alpha$ -*m*-4-*xylyl*- $\beta$ -*ethyl*- $\Delta^{\alpha}$ -*butene*, b.p. 242°(corr.)/760 mm.; 122–123°/10–11 mm.;  $\alpha$ -*m*-4-*xylyl*- $\beta$ -*propyl*- $\Delta^{\alpha}$ -*pentene*, b.p. 137–138°(corr.)/13 mm.;  $\alpha$ -*m*-4-*xylyl*- $\beta$ -*n-butyl*- $\Delta^{\alpha}$ -*hexene*, b.p. 286–288°/760 mm., 173°(corr.)/20 mm.;  $\beta\beta$ -*diphenyl*- $\beta$ -*m*-4-*xylylethylene*, m.p. 69–70° (block);  $\gamma$ -*phenyl*- $\alpha$ -*m*-4-*xylyl*- $\beta$ -*benzyl*- $\Delta^{\alpha}$ -*propene*, b.p. 246°/13 mm. Reduction of the *Me* ester by Na and EtOH leads to  $\beta$ -*m*-4-*xylylethyl alcohol*, (V), b.p. 101–102°/3 mm.; 125°(corr.)/10 mm. [*phenylurethane*, m.p. 124.5–125° (block); *allophanate*, m.p. 222° (block)] transformed by  $SOCl_2$  and  $C_5H_5N$  into the corresponding *chloride* (VI), b.p. 111.5°(corr.)/11 mm., by  $PBr_3$  into the *bromide*, b.p. 132°(corr.)/18 mm.; the *iodide* from (VI) and NaI in  $COMe_2$ , has b.p. 136–137°/12 mm. The corresponding normal *sulphite*, b.p. 216–217°/2 mm., passes when heated into the alcohol,  $SO_2$ , and *m*-4-*xylylethylene*, b.p. 81–85°/14 mm. The *acetate*, b.p. 135°/14 mm., normal *oxalate*, m.p. 73–73.5° (block), and *benzoate*, b.p. 182°/12 mm., of (V) are described. (V) is transformed by  $NaHSO_4$  at 160–170° into *di*- $\beta$ -*m*-4-*xylylethyl ether*, m.p. 38°. H. W.

**Alkylene- and alkylidene-phenylacetoneitriles and derivatives.** 1-Cyano-1-phenyl-2-ethyl-cyclopropane and  $\alpha$ -phenyl- $\beta$ -ethyl- and  $\beta$ -*iso*-propyl-acrylonitriles. J. V. MURRAY and J. B.

CLOKE (J. Amer. Chem. Soc., 1936, 58, 2014—2018; cf. A., 1932, 739).— $\text{CH}_2\text{Ph}\cdot\text{CN}$  (I) is treated with  $\text{NaNH}_2$  (2 mols.) in liquid  $\text{NH}_3$  (which is then replaced by  $\text{Et}_2\text{O}$ ) followed by  $\text{CH}_2\text{Cl}\cdot\text{CH}\cdot\text{EtCl}$ , thus giving 40% of 1-cyano-1-phenyl-2-ethylcyclopropane, b.p. 93—94°/1 mm., which is hydrolysed ( $\text{AcOH}\cdot\text{H}_2\text{SO}_4$  or  $\text{EtOH}\cdot\text{KOH}$ ) to 1-phenyl-2-ethylcyclopropane-1-carboxylamide, m.p. 84°, and thence ( $\text{EtOH}\cdot\text{KOH}$ ) to the acid, m.p. 105—105.5° (corr.). (I) and  $\text{CH}_2\text{Cl}\cdot\text{CMe}_2\text{Cl}$  similarly afford 38% of  $\alpha$ -phenyl- $\beta$ -isopropylacrylonitrile (II), b.p. 95—95.2°/1 mm., probably formed by rearrangement of the intermediate  $\text{CMe}_2\text{CH}\cdot\text{CHPh}\cdot\text{CN}$ . (II), also obtained in 85% yield from (I) and  $\text{Pr}^i\text{CHO}$  in  $\text{EtOH}\cdot\text{NaOEt}$  at  $<-5^\circ$ , is hydrolysed ( $\text{AcOH}\cdot\text{H}_2\text{SO}_4$ ) to  $\alpha$ -phenyl- $\beta$ -isopropylacrylamide, m.p. 123—124° (corr.) [free acid, m.p. 133—134° (corr.)], and converted by alkaline  $\text{H}_2\text{O}_2$  in  $\text{CMe}_2$  (cf. A., 1935, 212) into  $\alpha\beta$ -oxido- $\alpha$ -phenylisohexoamide, m.p. 148—149° (corr.). Oxidation ( $\text{KMnO}_4$ , aq.  $\text{Na}_2\text{CO}_3$ ) of (II) gives  $\text{BzOH}$ ,  $\text{Pr}^i\text{CO}_2\text{H}$ , and  $\text{HCN}$ . (I) and  $\text{EtCHO}$  in  $\text{EtOH}\cdot\text{NaOEt}$  similarly afford  $\alpha$ -phenyl- $\beta$ -ethylacrylonitrile [ $\alpha$ -phenyl- $\Delta^2$ -pentenonitrile], b.p. 112—112.5°/3 mm. (55% yield), converted [as for (II)] into  $\alpha$ -phenyl- $\Delta^2$ -pentenoamide, m.p. 130° (corr.) (free acid, m.p. 67.5—68.5°), and  $\alpha\beta$ -oxido- $\alpha$ -phenylvaleramide, m.p. 155° (corr.). H. B.

[Preparation of ethyl cyclopentanone-2-carboxylate.]—See this vol., 1482.

Compounds  $\text{LiCl}\cdot\text{o-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  and  $\text{LiCl}\cdot\text{o-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . K. SANDVED and R. VERMO (Tids. Kjem., 1936, 16, 115—116).—Phase-rule studies show the existence of these two compounds, which have been isolated together with the compound  $2\text{LiCl}\cdot\text{o-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ . M. H. M. A.

Hydrazino-acids. V. A. DARAPSKY [with J. LOEVENICH, O. CREIFELDS, W. BELLINGEN, E. KOSTER, V. BINET, H. WASSERFUHR, and H. BECK] (J. pr. Chem., 1936, [ii], 146, 268—306; cf. this vol., 1494).—Cautious addition of  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  to  $\text{CH}_2\text{Ph}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  in  $\text{EtOH}$  gives the hydrazine salt (I), m.p. 123°, of phenylpyruvic acid hydrazone, converted by dil.  $\text{HCl}$  into  $\text{CH}_2\text{Ph}\cdot\text{CO}\cdot\text{CO}_2\text{H}$ . (I) is reduced by  $\text{Na}\cdot\text{Hg}$  in  $\text{H}_2\text{O}$  to  $\alpha$ -hydrazino- $\beta$ -phenylpropionic acid, m.p. 196° [ $\text{CHPh}$  derivative, m.p. 154—158°].  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  in  $\text{C}_6\text{H}_6$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in  $\text{EtOH}$  give the hydrazine salt, m.p. 134—135°, of  $p$ -tolylglyoxylic acid hydrazone, which does not yield a  $\text{CHPh}$  derivative; it is converted by dil.  $\text{HCl}$  into  $p$ -tolylglyoxylic acid azine, [ $\text{N}\cdot\text{C}(\text{CO}_2\text{H})\cdot\text{C}_6\text{H}_4\text{Me}\cdot\text{p}$ ] $_2$ , m.p. 183° (decomp.), also obtained from  $\text{C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$  in  $\text{EtOH}\cdot\text{H}_2\text{O}$ , which is reduced by  $\text{Na}\cdot\text{Hg}$  to hydrazo- $p$ -tolylacetic acid, m.p. 149° (non-cryst. *Et* ester).  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  is transformed by successive treatment with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in  $\text{EtOH}\cdot\text{H}_2\text{O}$  at room temp. and  $\text{Na}\cdot\text{Hg}$  into hydrazino- $p$ -tolylacetic acid, m.p. 174—176° (hydrochloride, m.p. 143—145° (decomp.));  $\text{CHPh}$ , m.p. 130°, and *o*-hydroxybenzylidene, m.p. 150°, derivative; *Et* ester hydrochloride, m.p. 141—143° (decomp.); *Et* carbonamidohydrazino- $p$ -tolylacetate, m.p. 130°. *Et* nitrosohydrazino- $p$ -tolylacetate, m.p. 70°, passes when heated above its m.p. into  $\text{N}_2\text{O}$  and *Et* amino- $p$ -tolylacetate, b.p. 136—139°/12

mm., hydrolysed to amino- $p$ -tolylacetic acid, sublimes at 228° (*Cu* salt). The phenylhydrazone of  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  is reduced by  $\text{Na}\cdot\text{Hg}$  to phenylhydrazino- $p$ -tolylacetic acid, m.p. 148°. *Et* azido- $p$ -tolylacetate, b.p. 155°/18 mm., from the  $\text{NO}$ -ester and 10%  $\text{H}_2\text{SO}_4$ , is hydrolysed to azido- $p$ -tolylacetic acid, m.p. 100° ( $\text{NH}_4$  and *Ag* salts).  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CO}_2\text{H}$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in abs.  $\text{EtOH}$  give benzylpyruvic acid hydrazone, m.p. 133—134° (decomp.), the  $\text{N}_2\text{H}_4$  salt (II), m.p. 141°, of which is converted by dil.  $\text{HCl}$  into the azine, m.p. 114°, of benzylpyruvic acid (*Ca* salt), reduced by  $\text{Na}\cdot\text{Hg}$  to hydrazo- $\gamma$ -phenyl-*n*-butyric acid, decomp. 220—230°. (II) is reduced by  $\text{Na}\cdot\text{Hg}$  to  $\alpha$ -hydrazino- $\gamma$ -phenyl-*n*-butyric acid (III), m.p. 215—217° (decomp.) [ $\text{NH}_4$ , m.p. 203—204° (decomp.), and *Cu*, decomp. 115° after becoming red at 60—70°, salts; hydrochloride, m.p. 187° (decomp.);  $\text{CHPh}$  derivative, m.p. 158° (decomp.); *Et* ester hydrochloride, m.p. 108°]. (III) is transformed by  $\text{HBr}\cdot\text{Br}$  at 0° into  $\alpha$ -bromo- $\gamma$ -phenyl-*n*-butyric acid, reconverted into (III) by  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in boiling  $\text{EtOH}$ . *Et*  $\alpha$ -nitrosohydrazino- $\gamma$ -phenyl-*n*-butyrate, m.p. 48°, passes at 115—120° into *Et*  $\alpha$ -amino- $\gamma$ -phenyl-*n*-butyrate, b.p. 161—162°/16 mm. [hydrochloride, m.p. 121—123° (decomp.)], hydrolysed to  $\alpha$ -amino- $\gamma$ -phenyl-*n*-butyric acid, m.p. 292—293° when rapidly heated. *Et*  $\alpha$ -azido- $\gamma$ -phenyl-*n*-butyrate, b.p. 172—173°/16 mm., gives the non-cryst.  $\alpha$ -azido- $\gamma$ -phenyl-*n*-butyric acid ( $\text{NH}_4$ , m.p. 118—120°, and *Ag* salt).  $\text{CHPhMe}\cdot\text{CHBr}\cdot\text{CO}_2\text{H}$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in boiling  $\text{EtOH}$  give  $\alpha$ -hydrazino- $\beta$ -phenyl-*n*-butyric acid, m.p. 216° [ $\text{NH}_4$  salt; hydrochloride, m.p. 172—173° (decomp.); unstable  $\text{CHPh}$ , m.p. 107° (indef.), and *o*-hydroxybenzylidene, m.p. 133° (decomp.), derivatives; *Me*, m.p. 58—60°, and non-cryst. *Et* ester hydrochloride]. *Me*  $\alpha$ -nitrosohydrazino- $\beta$ -phenyl-*n*-butyrate passes at 120—130° into *Me*  $\alpha$ -amino- $\beta$ -phenyl-*n*-butyrate, b.p. 145—155°/13 mm. (hydrochloride, decomp. 170°), whence  $\alpha$ -amino- $\beta$ -phenyl-*n*-butyric acid, m.p. 239° (lit. m.p. 247—252°) (hydrochloride, m.p. 198°), and is transformed by steam-distillation in presence of 10%  $\text{H}_2\text{SO}_4$  into  $\alpha$ -azido- $\beta$ -phenyl-*n*-butyric acid ( $\text{NH}_4$ , m.p. 144°, and *Ag* salt).  $\text{Ph}\cdot[\text{CH}_2]_3\cdot\text{CHBr}\cdot\text{CO}_2\text{H}$  affords  $\alpha$ -hydrazino- $\beta$ -phenyl-*n*-butyric acid, m.p. 169—172° (decomp.) [hydrochloride, m.p. 132—135°;  $\text{CHPh}$ , m.p. 109—112°, and *o*-hydroxybenzylidene, m.p. 112—113°, derivatives; *Ac* $_2$ , m.p. 155° (decomp.), and *Bz* $_2$ , m.p. 139—141°, compounds; non-cryst. *Me* and *Et* ester hydrochlorides].  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  and  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in boiling  $\text{EtOH}$  give benzylidenepyruvic acid hydrazone, m.p. 84° (decomp.), the  $\text{N}_2\text{H}_4$  salt, m.p. 92°, of which could not be transformed into the corresponding azine, but is reduced by  $\text{Na}\cdot\text{Hg}$  to  $\alpha$ -hydrazino- $\gamma$ -phenyl-*n*-butyric acid, m.p. 215—217°.  $\text{CHPh}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  gives the  $\text{N}_2\text{H}_4$  salt, m.p. 125° (decomp.), of cinnamylidenepyruvic acid hydrazone, which yields an impure azine and is reduced to  $\alpha$ -hydrazino- $\epsilon$ -phenyl-*n*-hexoic acid, m.p. 157° [ $\text{CHPh}$ , m.p. 124° (decomp.), and *o*-hydroxybenzylidene, m.p. 120°, derivatives; *Ac* $_2$ , m.p. 127°, and *Bz* $_2$ , m.p. 65°, compounds; non-cryst. *Me* and *Et* ester hydrochlorides]. *Et*  $\alpha$ -nitrosohydrazino- $\epsilon$ -phenyl-*n*-hexoate gives  $\alpha$ -amino- $\epsilon$ -phenyl-*n*-hexoic acid, m.p. 233—236°, and  $\alpha$ -azido- $\epsilon$ -phenyl-*n*-hexoic acid (*Ag* salt, m.p. 111—112°).  $1\text{-C}_{10}\text{H}_7\cdot\text{CO}\cdot\text{CO}_2\text{H}$

affords the  $N_2H_4$  salt, m.p.  $188^\circ$  after becoming discoloured, of 1-naphthylglyoxylic acid hydrazone whence the corresponding azine,  $[N:C(C_{10}H_7) \cdot CO_2H]_2$ , m.p.  $160$ — $162^\circ$  (decomp.), reduced to *hydrazo- $\alpha$ -naphthylacetic acid*, m.p.  $186$ — $188^\circ$  (decomp.) (non-cryst. *Et* ester). *Hydrazino-1-naphthylacetic acid*, m.p.  $181^\circ$  after darkening at  $175$ — $176^\circ$ , gives a *hydrochloride*, m.p.  $194^\circ$ , a *CHPh*, m.p.  $124^\circ$  (decomp.) after darkening at about  $110^\circ$ , and *o-hydroxybenzylidene*, m.p.  $70^\circ$  (decomp.) after darkening at  $50^\circ$ , derivatives. It does not condense with  $COMe_2$  or give a cryst. Ac derivative and is not esterified by  $HCl$ - $MeOH$  or  $HCl$ - $EtOH$ . H. W.

**Diaryls and their derivatives. XI. Structure and composition of the complex compound of iron with  $\beta$ -naphthol-3-carboxylic acid.** J. S. JOFFE and M. I. KRILOVA (J. Gen. Chem. Russ., 1936, 6, 1006—1013).—Addition of aq.  $FeCl_3$  to aq. 2 : 3- $OH \cdot C_{10}H_6 \cdot CO_2Na$  leads to the production of a complex salt,  $[(O \cdot C_{10}H_6 \cdot CO_2)_2Fe]_3 \cdot 18H_2O$ , which is oxidised by excess of  $FeCl_3$  to yield a salt of Fe with 2 : 2'-dihydroxy-1 : 1'-dinaphthyl-2 : 2'-dicarboxylic acid,  $[(O \cdot C_{10}H_5 \cdot CO_2)_2Fe]$ . R. T.

**Condensation of phenylpyruvic acid with acetophenone.** P. CORDIER (J. Pharm. Chim., 1936, [viii], 24, 345—352).— $CH_2Ph \cdot CO \cdot CO_2Na$  with  $COPhMe$  in aq.  $EtOH$ - $KOH$  at room temp. affords the Na salt of  $\alpha$ -hydroxy- $\alpha$ -phenacyl- $\beta$ -phenylpropionic acid (liberated by acidification), dehydrated by  $HCl$ - $AcOH$  at  $100^\circ$  or by heat alone to give 2-*keto-5-phenyl-3-benzylidene-2 : 3-dihydrofuran*,  $O \begin{array}{c} \diagup CO \cdot C \cdot CHPh \\ \diagdown CPh \cdot CH \end{array}$  (I), m.p.  $150^\circ$  (insol. in  $Na_2CO_3$ ), and  $\alpha$ -phenacyl- $\beta$ -phenylacrylic acid (or  $\beta$ -benzoyl- $\alpha$ -benzylacrylic acid), decomp.  $160^\circ$ , also obtained by the action of boiling alkali on (I). J. W. B.

**Synthesis of pharmacologically important carboxylic acids. II. Synthesis of substituted phenylacetic acids from aromatic aldehydes.** K. KINDLER and E. GEHLHAAR (Arch. Pharm., 1936, 274, 377—388; cf. A., 1933, 1293).—*p*-Methylmandelonitrile *O*-benzoate reduced by Pd-black (I) and boiling tetrahydronaphthalene (II) and subsequently hydrolysed (aq.  $KOH$ ,  $EtOH$ ) gives *p*-tolylacetic acid, m.p.  $91$  (60% yield). *p*-isoPropylphenylacetic acid was similarly obtained. Hydrogenation [(I) and boiling (II) at 2 atm.; (I) and  $AcOH$ ] of mandelamide *O*-benzoate yields  $BzOH$  and  $CH_2Ph \cdot CO \cdot NH_2$  (75% yield). Mandelonitrile *O*-benzoate in aq.  $MeOH$  with  $HCl$  yields *Me benzoyl-mandelate*, m.p.  $78^\circ$ , which by the above methods of hydrogenation and subsequent hydrolysis gives  $CH_2Ph \cdot CO_2H$  (84% yield). By the action of  $HCl$  in aq.  $MeOH$  on the corresponding nitriles are obtained *Me O-acetyl-3 : 4-dimethoxymandelate*, b.p.  $186$ — $196^\circ/14$  mm., -4-methoxymandelate, b.p.  $164$ — $174^\circ/15$  mm., and -mandelate, b.p.  $144^\circ/15$  mm., which by hydrogenation [2 atm.; (I) and  $AcOH$ ] and hydrolysis yield homoveratric acid (III). *p*- $OMe \cdot C_6H_4 \cdot CH_2 \cdot CO_2H$ , and  $CH_2Ph \cdot CO_2H$ , respectively, in good yield. 3 : 4-( $OEt$ ) $_2C_6H_3 \cdot CHO$  in aq.  $MeOH$  hydrogenated by (I) yields 3 : 4-( $OEt$ ) $_2C_6H_3 \cdot CH_2 \cdot OH$ , which with  $SO_2Cl$  gives 3 : 4-( $OEt$ ) $_2C_6H_3 \cdot CH_2Cl$ , and this in  $C_6H_6$  with  $KCN$  in  $H_2O$  yields 3 : 4-diethoxyphenylacetoneitrile,

b.p.  $175$ — $180^\circ/14$  mm., m.p.  $37^\circ$ , hydrolysed ( $KOH$ ; aq.  $EtOH$ ) to 3 : 4-diethoxyphenylacetic acid, m.p.  $79$ — $80^\circ$ , all obtained in good yields. A good yield of (III) was similarly obtained from 3 : 4-( $OMe$ ) $_2C_6H_3 \cdot CHO$ . F. R. G.

**2 : 2-Disubstituted indandiones.** G. N. GHEORGHIU (J. pr. Chem., 1936, [ii], 146, 193—197).—*Me 2-methylindandione-2-acetate*, m.p.  $163$ — $164^\circ$ , obtained by the successive action of  $KOH$ - $EtOH$  and  $CH_2Br \cdot CO_2Me$  on 2-methylindandione, is hydrolysed by 20%  $H_2SO_4$ - $AcOH$  at  $150^\circ$  to the corresponding acid, m.p.  $190^\circ$ .  $CH_2Br \cdot CO_2Et$  similarly gives *Et 2-methylindandione-2-acetate*, m.p.  $159$ — $161^\circ$ , and, after re-solidification, m.p.  $161$ — $162^\circ$ . The following 2-methylindandiones are obtained analogously: 2-benzyl-, m.p.  $78$ — $79^\circ$ ; 2-acetonyl-, m.p.  $136$ — $137^\circ$ . 2-Phenylindandione yields 2-acetonyl-, m.p.  $152$ — $153^\circ$  [accompanied by the compound (?)  $CO(CH_2 \cdot CPh < \begin{array}{c} CO \\ CO \end{array} C_6H_4)_2$ , m.p.  $208$ — $210^\circ$ , arising from  $CO(CH_2Br)_2$  present in  $CH_2BrAc$ ], and 2-allyl-, m.p.  $76^\circ$ , 2-phenylindandione, and *Et 2-phenylindandione-2- $\beta$ -propionate*, m.p.  $72$ — $74^\circ$ . H. W.

**Lichen substances. LXXI. Synthesis of diploschistessic acid.** Y. ASAHINA and M. YASUE (Ber., 1936, 69, [B], 2327—2330; cf. Koller *et al.*, A., 1935, 748).—Treatment of gallaldehyde  $Me_3$  ether with  $N_2H_4 \cdot H_2O$  in boiling  $EtOH$  and of the residue with  $KOH$  at  $120^\circ$  gives 5-methylpyrogallol  $Me_3$  ether, b.p.  $117$ — $118^\circ/5$  mm., demethylated by boiling  $HI$  ( $d$  1.7) to 5-methylpyrogallol (I). 2 : 3 : 4-Trihydroxy-6-methylbenzaldehyde, m.p.  $182$ — $183^\circ$  or,  $+1H_2O$ , m.p.  $182$ — $183^\circ$  after softening at about  $120^\circ$ , obtained from (I),  $Zn(CN)_2$ , and  $HCl$  in abs.  $Et_2O$ , is converted by  $ClCO_2Et$  and  $C_5H_5N$  in  $COMe_2$  at  $0^\circ$  into 2 : 3 : 4-triethylcarbonato-6-methylbenzaldehyde, m.p.  $66$ — $68^\circ$ , oxidised by  $KMnO_4$  in  $COMe_2$ - $H_2O$  at  $45^\circ$  to 2 : 3 : 4-triethylcarbonato-6-methylbenzoic acid (II), m.p.  $109^\circ$ . (II) is converted by successive treatments with  $SOCl_2$  and oreylaldehyde into tricarbethoxydiploschistessic aldehyde, m.p.  $136$ — $138^\circ$ , which is condensed with  $ClCO_2Et$  in  $C_5H_5N$  and then oxidised to tetracarbethoxydiploschistessic acid, m.p.  $131$ — $132^\circ$ , hydrolysed by  $NaOH$  in  $COMe_2$ - $H_2O$  to diploschistessic acid (4 : 2' : 3' : 4'-trimethoxy-6'-methylbenzoyl-3-hydroxy-5-methylbenzoic acid), m.p.  $174^\circ$  (decomp.) (tetraacetate, m.p.  $164$ — $165^\circ$ , and its *Me* ester, m.p.  $169^\circ$ ). H. W.

**Lichen substances. LXX. Synthesis of ramalinolic acid.** Y. ASAHINA and T. KUSAKA (Ber., 1936, 69, [B], 1896—1899).—3 : 4 : 5-Trimethoxyvalerophenone is reduced by  $Zn$ - $Hg$  and boiling 5*N*- $HCl$  to 5-*n*-amylpyrogallol  $Me_3$  ether, b.p.  $166^\circ/6$  mm., converted by red P and boiling  $HI$  ( $d$  1.7) into 5-*n*-amylpyrogallol, b.p.  $179$ — $182^\circ/3$  mm., m.p.  $67^\circ$ . Treatment of (I) and  $Zn(CN)_2$  in  $Et_2O$  with  $HCl$  and of the product with boiling  $H_2O$  yields 2 : 3 : 4-trihydroxy-6-*n*-amylbenzaldehyde (I), m.p.  $116$ — $117^\circ$ , transformed by  $ClCO_2Et$  in  $C_5H_5N$  at  $-15^\circ$  and then oxidised by  $KMnO_4$  in  $COMe_2$  to 2 : 3 : 4-triethylcarbonato-6-*n*-amylbenzoic acid, m.p.  $81^\circ$ , whence 2 : 3 : 4-trihydroxy-6-*n*-amylbenzoic acid, m.p.  $163^\circ$ . Treatment of (I) with carbethoxydivaricatyl chloride gives the *depside aldehyde* (II),

which, after protection of the free OH groups by  $\text{CO}_2\text{Et}$ , is oxidised to the corresponding acid; this,

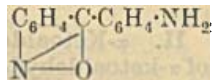

after decarboxylation, gives a product identical with natural ramalinic acid (III). (I) in  $\text{COMe}_2$  is transformed by  $\text{BzCl}$  and  $N\text{-KOH}$  into 2:4-dihydroxy-3-benzoyloxy-6-n-amybenzaldehyde (V), m.p.  $123^\circ$ , the dicarboxy-derivative of which is oxidised and then decarboxylated to 2:4-dihydroxy-3-benzoyloxy-6-n-amybenzoic acid, m.p.  $173^\circ$ . (IV) in  $\text{COMe}_2$  is converted by  $\text{MeI}$  and anhyd.  $\text{K}_2\text{CO}_3$  into an oil, oxidised by  $\text{KMnO}_4$  to 2:4-dimethoxy-3-benzoyloxy-6-n-amybenzoic acid, m.p.  $162\text{--}163^\circ$ ; the corresponding Me ester is hydrolysed by  $\text{KOH-MeOH}$  to the substance  $\text{C}_{15}\text{H}_{22}\text{O}_5$ , m.p.  $73\text{--}74^\circ$ , identical with that obtained by hydrolysis of permethylated (III). H. W.

Elimination of the aldehydic group as formic acid from aromatic aldehydes. IV. 2-Chloro-6-fluoro- and 2:6-difluoro-benzaldehyde. G. LOCK (Ber., 1936, **69**, [B], 2253—2258; cf. A., 1935, 1238).—With di-ortho-substituted benzaldehydes the behaviour of F resembles that of other halogens. 2:6- $\text{C}_6\text{H}_3\text{MeClF}$  is converted by gradual treatment with Br at  $180\text{--}200^\circ$  and of the product with conc.  $\text{H}_2\text{SO}_4$  at  $50\text{--}60^\circ$  followed by distillation with steam into 2-chloro-6-fluorobenzaldehyde (I), m.p.  $38\text{--}5^\circ$  [semicarbazone, m.p.  $213^\circ$  (corr.); oxime, m.p.  $134^\circ$  (corr.)], oxidised by  $\text{Ag}_2\text{O-H}_2\text{O}$  at  $100^\circ$  to 2-chloro-6-fluorobenzoic acid (II), m.p.  $159^\circ$  (corr.). (I) and 50%  $\text{KOH-H}_2\text{O}$  at  $100^\circ$  afford  $\text{HCO}_2\text{H}$ , a little (II), and m-chlorofluorobenzene, b.p.  $127\text{--}128^\circ/761\text{ mm.}$ , also obtained from m- $\text{C}_6\text{H}_4\text{Cl}\cdot\text{NH}_2$ . 2:6- $\text{NO}_2\cdot\text{C}_6\text{H}_3\text{Me}\cdot\text{NH}_2$  is converted into the corresponding diazonium borofluoride, decomp.  $118^\circ$ , which when heated with sand at  $150\text{--}250^\circ/\text{vac.}$  affords 2-fluoro-6-nitrotoluene (III), b.p.  $97^\circ/11\text{ mm.}$ , m.p.  $6\text{--}5\text{--}7^\circ$ . (III) is reduced ( $\text{SnCl}_4$  and conc.  $\text{HCl}$ ) to 6-fluoro-o-toluidine, b.p.  $89\text{--}90\text{--}90\text{--}5^\circ/15\text{ mm.}$ , m.p.  $7^\circ$  [*Ac* derivative, m.p.  $132^\circ$  (corr.)], transformed through the diazonium borofluoride into 2:6-difluorotoluene (IV), b.p.  $112^\circ$  (corr.)/ $742\text{ mm.}$  [2-fluoro-6-hydroxytoluene, b.p.  $186\text{--}188^\circ$  (corr.)/ $748\text{ mm.}$ , m.p.  $56\text{--}5^\circ$ ]. The direct prep. of (IV) from 2:6- $\text{C}_6\text{H}_3\text{Me}(\text{NO}_2)_2$  appears impossible. (IV) is brominated at its b.p. to 2:6-difluorobenzylidene bromide, m.p.  $45^\circ$ , converted by  $\text{H}_2\text{SO}_4$  into 2:6-difluorobenzaldehyde (V), b.p.  $82\text{--}84^\circ/15\text{ mm.}$ ,  $190\text{--}195^\circ/743\text{ mm.}$ , m.p. about  $15\text{--}17^\circ$  [semicarbazone, m.p.  $226^\circ$  (corr.); 2:6-difluorobenzoic acid, m.p.  $157\text{--}5^\circ$  (corr.)], also obtained from (IV) by Etard's reaction. (V) and 50%  $\text{KOH}$  yield  $\text{HCO}_2\text{H}$  and m- $\text{C}_6\text{H}_4\text{F}_2$ . H. W.

Condensation of 5-chloro-2-nitrobenzaldehyde with aniline. I. TANASESCU and (MLLE.) M. SUCIU (Bull. Soc. chim., 1936, [v], **3**, 1753—1761).—2:5- $\text{NO}_2\cdot\text{C}_6\text{H}_3\text{Cl}\cdot\text{CHO}$  and  $(\text{NH}_2\text{Ph})_2\cdot\text{H}_2\text{SO}_4$ —condense ( $\text{ZnCl}_2$ ) to form o-chloro-2-nitro-4':4''-diaminotriphenylmethane (I), m.p.  $164^\circ$  (hydrochloride; *Ac.*, m.p.  $209^\circ$ , and *Bz.*, m.p.  $253^\circ$ , derivatives), which with  $\text{Zn-NH}_4\text{Cl-EtOH}$  gives o-chloro-2:4':4''-tri-

aminotriphenylmethane, m.p.  $98^\circ$  (*Bz.* derivative, m.p.  $260^\circ$ ). As by-product with (I), 5-chloro-3-p-aminophenylanthranil, m.p.  $208^\circ$  (*Ac.*, m.p.  $222^\circ$ , *Bz.*, m.p.  $242^\circ$ , benzylidene, m.p.  $149^\circ$ , and 5''-chloro-2''-nitrobenzylidene, m.p.  $245^\circ$ , derivatives), is formed, which with  $\text{Zn-NH}_4\text{Cl-EtOH}$  gives 5-chloro-2:4'-diaminobenzophenone, m.p.  $149^\circ$  (*Bz.* derivative, m.p.  $207^\circ$ ). E. W. W.

Action of aniline on o-nitrobenzaldehyde in acetic acid. S. SECAREANU and A. SILBERG (Bull. Soc. chim., 1936, [v], **3**, 1777—1782).—These substances condense in  $\text{AcOH}$  to give a product, converted by conc.  $\text{HCl}$  in  $\text{EtOH}$  into a mixture of 3-p-amino-

phenylanthranil, , and 5-chloro-3-p-aminophenylanthranil (cf. preceding abstract). E. W. W.

Formation of polyene chains. Preparation of unsaturated aldehydes. G. WITTIG and R. KETHUR [with, in part, A. KLEIN and R. WIETBROCK] (Ber., 1936, **69**, [B], 2078—2087).—The syntheses follow the course  $\text{R}\cdot\text{CHO} + \text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{H} \rightarrow \text{CHR}\cdot\text{C}(\text{CN})\cdot\text{CO}_2\text{H} \rightarrow \text{CHR}\cdot\text{CH}\cdot\text{CN} \rightarrow \text{CHR}\cdot\text{CH}\cdot\text{CH}\cdot\text{NH} \rightarrow \text{CHR}\cdot\text{CH}\cdot\text{CHO}$ .  $\text{CHPh}\cdot\text{CH}\cdot\text{CHO}$  and  $\text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  in boiling  $\text{AcOH}$  afford cinnamylidenecyanoacetic acid, which loses  $\text{CO}_2$  when heated with  $\text{Cu}$  powder at  $180\text{--}185^\circ$  giving cinnamylideneacetonitrile (I), b.p.  $158\text{--}160^\circ/11\text{ mm.}$ , converted by  $\text{HCl}$  in abs.  $\text{Et}_2\text{O}$  followed by treatment of the hydrochloride with  $\text{H}_2\text{O}$  into the solid isomeride (II), m.p.  $40\text{--}41\text{--}5^\circ$ . (I) and (II) give the same cinnamylidene-acetamide, m.p.  $185\text{--}5\text{--}186\text{--}5^\circ$ , and -acetic acid, m.p.  $163\text{--}164^\circ$ , when subjected to short and protracted hydrolysis with  $\text{KOH-EtOH}$ , respectively. Reduction of (I) or (II) to the corresponding aldehyde by  $\text{SnCl}_2\text{-SnCl}_4\cdot 2\text{H}_2\text{O}$  and  $\text{HCl}$  in  $\text{Et}_2\text{O}$  is unsatisfactory by reason of the sparing solubility of the intermediate adducts and the best yields of  $\delta$ -phenyl- $\Delta^{\alpha\gamma}$ -pentadienal (phenylhydrazone, m.p.  $173\text{--}5\text{--}174^\circ$ ) are secured in dioxan at  $55^\circ$ . Cinnamylideneacetaldehyde and  $\text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  give  $\alpha$ -cyano- $\zeta$ -phenyl- $\Delta^{\alpha\gamma\epsilon}$ -heptatrienoic acid, m.p.  $227\text{--}228^\circ$ , converted by  $\text{Cu}$  powder at about  $190^\circ$  into  $\text{CO}_2$  and  $\zeta$ -phenyl- $\Delta^{\alpha\gamma\epsilon}$ -heptatrienonitrile, b.p.  $195\text{--}197^\circ/12\text{ mm.}$ , m.p.  $50\text{--}55^\circ$ , a mixture of stereoisomerides from which a form, m.p.  $111\text{--}112^\circ$ , is obtained by the action of  $\text{HCl}$  in  $\text{Et}_2\text{O}$ ; this is also produced when the mixture is reduced by  $\text{SnCl}_2$  and  $\text{HCl}$  in  $\text{Et}_2\text{O}$  or dioxan.

$\text{CPh}_2\cdot\text{Me}\cdot\text{OH}$  is transformed by  $\text{HBr}$  in boiling  $\text{AcOH}$  into  $\text{CPh}_2\cdot\text{CH}_2$ ;  $\text{Br}$  in  $\text{AcOH}$  is added to the cooled solution, which is again heated, whereby the intermediate  $\text{CPh}_2\cdot\text{Br}\cdot\text{CH}_2\cdot\text{Br}$  is transformed into  $\text{CPh}_2\cdot\text{CHBr}$  in 66% yield. The Grignard compound from the latter substance and  $\text{HCO}\cdot\text{NPhMe}$  afford  $\beta$ -phenylcinnamaldehyde (III), m.p.  $44\text{--}45^\circ$  (semicarbazone, m.p.  $217\text{--}219^\circ$ ; anilide, m.p.  $98\text{--}98\text{--}8^\circ$ , azine, m.p.  $199\text{--}199\text{--}5^\circ$ ), in 41% yield. (III) and  $\text{CN}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  in boiling  $\text{AcOH}$  yield  $\gamma$ -phenylcinnamylidenecyanoacetic acid, m.p.  $217\text{--}218^\circ$  (decomp.), whence  $\gamma$ -phenylcinnamylideneacetonitrile, m.p.  $68\text{--}69^\circ$ , and  $\delta\delta$ -diphenyl- $\Delta^{\alpha\gamma}$ -pentadienal, m.p.  $69\text{--}5\text{--}71^\circ$  (corresponding azine, m.p.  $183\text{--}184^\circ$ ). H. W.

**Condensation reactions of 2:4-dinitrophenylhydrazine.** F. L. RODUTA and G. QUITILAN (Rev. Filipina Med. Farm., 1936, 27, 123—130).—A summary of the known 2:4-dinitrophenylhydrazones of aldehydes and ketones is given and 2:4-dinitrophenylhydrazones of the following have been prepared: citral, m.p. 103°;  $\text{CCl}_3\cdot\text{CHO}$ , m.p. 131°; hydrocinnamaldehyde, m.p. 147°; furfuraldehyde, m.p. 218°; protocatechualdehyde, m.p. 226°;  $\text{COPh}_2$ , m.p. 228°;  $p\text{-NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ , m.p. 232°;  $\text{PhCHO}$ , m.p. 235°;  $\alpha$ -naphthaquinone, m.p. 278° (decomp.); and isatin. F. R. S.

[Halogeno-cinnamaldehydes.]—See this vol., 1463.

**Enol-betaines. II.  $\alpha$ -Ketoaldonitrone and a new preparation of  $\alpha$ -ketoaldehydes.** F. KROHNKE and E. BORNER (Ber., 1936, 69, [B], 2006—2016; cf. A., 1935, 987).—Addition of  $N\text{-NaOH}$  to phenacylpyridinium bromide (I) and  $\text{PhNO}$  in aq.  $\text{EtOH}$  at  $-10^\circ$  to  $-5^\circ$  affords *benzoyl-N-phenylnitrone* (II),  $\text{CHBz}\cdot\text{NPh}\cdot\text{O}$ , m.p. 109—110°, which gradually decomposes when kept and yields mandelic acid when treated with alkali. *Benzoylphenylnitrone hydrate* (III)  $\text{OH}\cdot\text{CHBz}\cdot\text{NPh}\cdot\text{OH}$ , m.p. 90°, is derived from (I) and  $0.1N\text{-H}_2\text{SO}_4$  in  $\text{EtOH}$ . (II) or (III) is transformed by  $\text{NHPH}\cdot\text{NH}_2$  (1 mol.) into a mixture of  $\alpha$ - and  $\beta$ -glyoxalphenylhydrazone and by excess of the reagent into the corresponding osazone. (II) and  $\text{NH}_2\text{OH}$  (1 mol.) yield oximinoacetophenone, whereas with 2 mols. *anti*-phenylglyoxime is produced. With  $\text{NH}_2\text{Ph}$  in hot  $\text{EtOH}$  (II) gives *phenylglyoxaldianil hydrate*,  $\text{C}_{20}\text{H}_{18}\text{ON}_2$ , m.p. 97° (corresponding *di-p-tolil hydrate*, m.p. 118—119°). The *p*-dimethylaminoanil of phenylglyoxal has m.p. 88°, and the *p*-dimethylaminoanilides of cinnamylideneacetic acid and  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}_2\text{H}$  have m.p. 205—207° and 174°, respectively. Analogous reactions between  $\text{PhNO}$  and phenacyl-quolinium, -isoquolinium, and -triethylammonium bromide and between phenacylpiperidinium bromide and  $p\text{-NO}\cdot\text{C}_6\text{H}_4\cdot\text{NMe}_2$  are described. *Benzoyl-N-p-dimethylaminophenylnitrone*, m.p. 110—111°, obtained as above or from the enolbetaine of (I) in absence of  $\text{NaOH}$ , is converted by  $5N\text{-H}_2\text{SO}_4$  into phenylglyoxal, m.p. 73° (A compound.  $2\text{-}p\text{-NO}\cdot\text{C}_6\text{H}_4\cdot\text{NMe}_2\cdot p\text{-NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{NMe}_2$ , m.p. 50—51° after softening at 48°, is described.) The oxime of phenacylpyridinium perchlorate and  $\text{PhNO}$  give the compound,  $\text{C}_{14}\text{H}_{12}\text{O}_2\text{N}_2$ , m.p. 156° (decomp.). The following -*benzoyl-N-p-dimethylaminophenylnitrone*s are described; *p*-iodo-, m.p. 97°, whence *p*-iodophenylglyoxal hydrate, m.p. 137—138°; 3:4-dichloro-, m.p. 136—137°, whence 3:4-dichlorophenylglyoxal hydrate, m.p. 82—84°; 3:4-dichloro-2-nitro-, decomp. about 140°. *p*-Phenylphenacylpyridinium bromide (IV) and  $\text{PhNO}$  afford *p-phenylbenzoyl-N-phenylnitrone*, m.p. 144°. Treatment of (IV) with  $p\text{-NO}\cdot\text{C}_6\text{H}_4\cdot\text{NMe}_2$  and alkali and of the product with warm, dil.  $\text{H}_2\text{SO}_4$  gives *p-xenylglyoxal hydrate*, m.p. 117—121°, also obtained by hydrolysis of *p-phenyl-p-bromophenacylpyridinium bromide*, m.p. 206° (decomp.), derived from (IV) and  $\text{Br}$  in  $\text{AcOH}$ ; *p-xenylquinoxaline* has m.p. 128°.  $\beta$ -Naphthacylpyridinium bromide gives  $\beta$ -naphthoyl-N-phenylnitrone, m.p. 101—101.5°, and  $\beta$ -naphthylglyoxal hydrate,

m.p. 106—109°. *Keto-2-thiophenonyl-N-p-dimethylaminophenylnitrone*, m.p. 123°, and non-homogeneous 2-thiophenylglyoxal hydrate are described. *Trimethylacetyl-N-p-dimethylaminophenylnitrone* has m.p. 87—88°. H. W.

**Synthesis of sesamol and its  $\beta$ -glucoside.** Baudouin's reaction. J. BOESEKEN, W. D. COHEN, and C. J. KIP (Rec. trav. chim., 1936, 55, 815—820).—Piperonaldehyde (I) and 20%  $\text{AcO}_2\text{H}$  (prep. free from  $\text{Ac}_2\text{O}_2$  described) in  $\text{AcOH}$  with 2 drops of  $\text{H}_2\text{SO}_4$  or, better, a trace of  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_3\text{H}$  at  $<30^\circ$  give 50 and 60% yields, respectively, of sesamol (II) and 0.7 mol. of  $\text{HCO}_2\text{H}$ . Larger amounts of acid cause resinification and very poor yields. (II), tetra-acetylglucosidyl bromide,  $2N\text{-KOH}$ , and  $\text{Et}_2\text{O}$ , when shaken, give sesamol  $\beta$ -glucoside tetra-acetate, cryst. (10%), hydrolysed by  $\text{Ba(OH)}_2$  to sesamol  $\beta$ -glucoside, m.p. 168—169°, which gives Baudouin's reaction slowly as does sesame oil; the reaction of the oil is thus proved to be due to hydrolysis of sesamoline to (II). Pure (II) colours rapidly in air, but this is prevented by a little (I). R. S. C.

**Reduction of benzophenone at the dropping mercury cathode.** H. SCHWEITZER and E. LAQUEUR (Rec. trav. chim., 1936, 55, 959—962).—Reduction of  $\text{COPh}_2$  at the dropping Hg cathode occurs in one stage in neutral solution, but in two stages in presence of  $\text{HCl}$ , particularly of an excess. Whereas reduction of the pinacone or its half-radical is possible, it is preferable to regard the reduction in acid solution as that of  $[\text{CPh}_2\cdot\text{OH}]^+\text{Cl}^-$ . R. S. C.

**Hydrogen linking formation between hydroxyl groups and nitrogen atoms in organic compounds.** S. B. HENDRICKS, O. R. WULF, G. E. HILBERT, and U. LIDDEL (J. Amer. Chem. Soc., 1936, 58, 1991—1996; cf. this vol., 703).—The existence of chelation between OH and N in compounds of the type  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{X}\cdot\text{NR}$  ( $\text{X}=\text{CH}$  or  $\text{N}$ ) is indicated by the absence of infra-red absorption characteristic of the OH group; such chelation requires the OH to be *trans* to R. Thus, the following show no absorption: (*anti*-)2-hydroxy-, m.p. 95°, and 2-hydroxy-5-methyl-, m.p. 114°, -benzophenoneoxime acetates (cf. Blatt, this vol., 1511), salicylaldehyde-anil-, hydrazine-, dimethylhydrazine-, phenylhydrazine-, phenylmethylhydrazine-, and -azine;  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OAc}$ ; 2:1- $\text{OH}\cdot\text{C}_{10}\text{H}_6\cdot\text{CPh}\cdot\text{N}\cdot\text{N}\cdot\text{CMe}_2$ ; 1-benzeneazo- and 2:5-dichlorobenzeneazo- $\beta$ -naphthols; 2:2'-dihydroxy- and 2:5:5'-trichloro-2'-hydroxy-4-methyl-azobenzene. Absorption is shown by  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{N}\cdot\text{OH}$  (probably due to  $\text{N}\cdot\text{OH}$ ), 2:1- $\text{OH}\cdot\text{C}_{10}\text{H}_6\cdot\text{CPh}\cdot\text{N}\cdot\text{NH}_2$  (m.p. 157°),  $o\text{-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CN}$ ,  $\alpha$ - and  $\beta$ -benzoinphenylhydrazones, 2:2'-dihydroxybenzophenone-oxime acetate and -phenylmethylhydrazine, and *syn*-2-hydroxybenzophenoneoxime acetate; in some cases, partial chelation probably occurs. Structural formulæ (showing probable interat. distances) for several of the above compounds are discussed. H. B.

**Oxidation of the ethylenic linking adjacent to a carbonyl group by peracids.** J. BOESEKEN and J. JACOBS (Rec. trav. chim., 1936, 55, 786—790).— $\text{CHPh}\cdot\text{CMe}\cdot\text{CMe}$  is oxidised by  $\text{AcO}_2\text{H}$  in  $\text{AcOH}$  at  $<30^\circ$  to (?) *cis*- and *trans*-forms, (I), m.p. 131°, and

(II), b.p. 100—103°/3 mm.,  $n_D$  1.5503, of the acetate of enolic benzyl Me ketone, hydrolysed by conc. HCl to  $\text{CH}_2\text{Ph}\cdot\text{COMe}$ . Neither is obtained from  $\text{CH}_2\text{Ph}\cdot\text{COMe}$  by  $\text{Ac}_2\text{O}\cdot\text{C}_6\text{H}_5\text{N}$ , but the Na derivative and  $\text{AcCl}$  in  $\text{Et}_2\text{O}$  give a poor yield of (II) with a little (I).  $\text{CHPh}\cdot\text{CH}\cdot\text{COEt}$ , b.p. 109—117°/3 mm., and  $\text{AcO}_2\text{H}$  give the propionate of enolic phenylacetaldehyde (III), b.p. 90—92°/1—3 mm.,  $n_D^{20}$  1.5541, hydrolysed by conc. HCl to  $\text{CH}_2\text{Ph}\cdot\text{CHO}$ . The aldehyde and  $(\text{EtCO})_2\text{O}\cdot\text{C}_6\text{H}_5\text{N}$  give an isomeride (IV), b.p. 92—96°/high vac.,  $n_D^{20}$  1.5371, of (III). Both (III) and (II) may be mixtures of isomerides. The action of  $\text{AcO}_2\text{H}$  is to insert O between the systems  $\cdot\text{C}\cdot\text{C}\cdot$  and  $\text{CO}$ .

R. S. C.

**Autoxidation phenomena in the indone series.** A. SCHONBERG and R. MICHAELIS (Naturwiss., 1936, 24, 620; cf. A., 1935, 1369).—2-*p*-Dimethylamino-anilino-3-phenylindone is autoxidised in solution by addition of  $\text{O}_2$  to the free radical form.

J. L. D.

**Synthesis of hexahydrophenanthrene derivatives.** J. C. BARDHAN (Chem. and Ind., 1936, 879—880).—The *cis*-structure assigned by van de Kamp and Mosettig (this vol., 1062) to liquid octahydrophenanthrene is uncertain.

$\text{CO}_2\text{Et}\cdot\text{CHAc}\cdot\text{CO}\cdot[\text{CH}_2]_3\cdot\text{CO}_2\text{Et}$ , b.p. 155°/1 mm., with  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\text{Br}$  and  $\text{NaOEt}$  give *Et*  $\beta$ -keto- $\alpha$ - $\beta'$ -phenylethylpimelate, b.p. 175°/1 mm., which with cold, conc.  $\text{H}_2\text{SO}_4$  affords *Et* 3:4-dihydronaphthalene-2-carboxylate-1- $\gamma$ -butyrate, b.p. 177°/1 mm. This undergoes ring-closure with Na and then yields by hydrolysis 1-keto-1:2:3:4:9:10-hexahydrophenanthrene, the semicarbazone, m.p. 254—255°, of which yields ( $\text{NaOEt}$ ) a hydrocarbon, smoothly dehydrogenated to phenanthrene.

R. S. C.

**Alkylation and arylation of benzanthrone by Grignard reagents.** Oxidative degradation of 6-phenylbenzanthrone. G. CHARRIER and E. CHIGI (Ber., 1936, 69, [B], 2211—2232; cf. A., 1933, 160).—Addition of benzanthrone (I) in  $\text{Et}_2\text{O}$  to  $\text{MgPrI}$  in  $\text{Et}_2\text{O}$  gives 6-propylbenzanthrone, m.p. 83—84°, oxidised by  $\text{CrO}_3$  in  $\text{AcOH}$  to 4-propylantraquinone-1-carboxylic acid, m.p. 180—181°. Similarly (I) and  $\text{MgBuI}$  afford 6-*n*-butylbenzanthrone, m.p. 99° [the *Bz*-3-*n*-butylbenzanthrone of Nakanishi (A., 1934, 191)], oxidised by  $\text{CrO}_3$  in  $\text{AcOH}$  to 4-*n*-butylantraquinone-1-carboxylic acid, m.p. 175°, and thence by  $\text{HNO}_3$  under pressure to anthraquinone-1:4-dicarboxylic acid, m.p. about 315°. Oxidation of 6-phenylbenzanthrone (II) with  $\text{KMnO}_4$  in boiling dil. alkali affords 4-phenylantraquinone-1-carboxylic acid (III), m.p. 288—290° [*Na* ( $3\text{H}_2\text{O}$ ) salt], diphenyl-3:4-dicarboxylic-2-glyoxylic acid (IV), m.p. 256—257° (decomp.), and  $\text{H}_2\text{C}_2\text{O}_4$ . Oxidation of (IV) with  $\text{KMnO}_4$  and 33%  $\text{H}_2\text{SO}_4$  yields diphenyl-2:3:4-tricarboxylic acid (V), m.p. 210—212°, which readily passes into an anhydride. Conc.  $\text{H}_2\text{SO}_4$  at 100° converts (IV) or (V) into fluorenone-1:2-dicarboxylic acid (VI), m.p. 330° (*Me* ester, m.p. 199°; *Me* *H* ester, m.p. about 230° and m.p. 315—320° after resolidification at 235—240°; anhydride, m.p. 315—320°), decarboxylated by Cu powder in quinoline at 150—160° and then at 200—210° to fluorenone-2-

carboxylic acid, m.p. 330° (*Me* ester, m.p. 186°). For purposes of comparison, diphenyl-2:3:2'-tricarboxylic acid (VI) is converted by conc.  $\text{H}_2\text{SO}_4$  at 150—160° into fluorenone-1:5-dicarboxylic acid, decarboxylated to fluorenone-1-carboxylic acid, m.p. 191—192° (*Me* ester, m.p. 89°). (V) and  $\text{NHPh}\cdot\text{NH}_2$  in boiling  $\text{EtOH}$  gave the corresponding phenylhydrazone, m.p. 305—307° (corresponding anhydride, m.p. 315°), and the phenylhydrazone of fluorenone-1:2-dicarboxyanilinoimide, m.p. 276° (decomp.). Oxidation of (IV) with alkaline  $\text{KMnO}_4$  gives (III), which is reduced by Zn in ammoniacal solution to 4-phenylantracene-1-carboxylic acid, m.p. 246—247°, decarboxylated by Cu in quinoline at 140—160° to 1-phenylantracene, m.p. 110—112°. Oxidation of (II) with  $\text{CrO}_3$  in  $\text{AcOH}\cdot\text{H}_2\text{SO}_4$  gives a product,  $\text{C}_{23}\text{H}_{14}\text{O}_2\cdot\text{CrO}_3$ , decomp. about 150°. Satisfactory oxidation of (II) by  $\text{CrO}_3$  in  $\text{AcOH}$  is secured if  $\text{H}_2\text{SO}_4$  is omitted and the change is allowed to proceed very vigorously, whereby small amounts of (III) and, mainly, 1:2-3:4-dibenzoxanthonecarboxylic acid (VII), m.p. 296—305° (decomp.), are produced. (VII) is neutral in cold solution, but readily yields the *Na*

salt ( $+3\text{H}_2\text{O}$ ) with boiling alkali or alkali carbonate. The *Me* ester (VIII) has m.p. 217°. (VII) is unattacked by boiling conc.  $\text{H}_2\text{SO}_4$  but is transformed by a large excess of boiling 20%  $\text{NaOH}$  into 9-*o*-hydroxybenzoylfluorene-1:9-dicarboxylic acid, m.p. 210—212° (decomp.), which gives a red colour with  $\text{FeCl}_3$ . Oxidation of (VII) with  $\text{KMnO}_4$  of differing concn. usually gives (VI) but under certain conditions  $\text{o-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  is isolable. Distillation of (VII) with Zn powder affords phenanthrene and 1:2-3:4-dibenzoxanthone (IX), m.p. 207—209°, together with  $\text{C}_6\text{H}_6$  and traces of  $\text{Ph}_2$  and  $\text{PhOH}$ . (IX) is very resistant towards oxidation but, under drastic conditions, is transformed by  $\text{KMnO}_4$  into diphenic acid. Distillation of (IX) over Zn powder affords mainly phenanthrene. Treatment of (IX) with  $\text{KOH}\cdot\text{EtOH}$  at 180° gives 9-hydroxy-10-*o*-hydroxybenzoylphenanthrene, m.p. 152°, readily re-converted into (VIII), whilst molten  $\text{KOH}$  at 250—280° gives  $\text{o-OH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$  and 9-hydroxyphenanthrene.

**Action of alkali on acylated ketoximes.** II. Steric hindrance to alkaline hydrolysis. A. H. BLATT and R. P. BARNES. III. Hydrogen bond formation in derivatives of *o*-hydroxybenzophenoneoximes. A. H. BLATT and L. A. RUSSELL (J. Amer. Chem. Soc., 1936, 58, 1900—1902, 1903—1908; cf. A., 1935, 1125).—II. Under conditions causing hydrolysis of  $\text{CPh}_2\cdot\text{N}\cdot\text{OBz}$ , and  $\alpha$ -*p*-chloro-, m.p. 114—115°,  $\alpha$ -*p*-methoxy-, m.p. 115—116°, and

$\beta$ -*p*-methoxy-, m.p. 85—86°, -benzophenoneoxime benzoates to oxime (and EtOBz), benzophenone-, m.p. 136—137°, and  $\alpha$ -*p*-chloro-, m.p. 101—102°,  $\alpha$ -*p*-methoxy-, m.p. 102—103°, and  $\beta$ -*p*-methoxy-, probably dimorphous, m.p. 75° and 120—121°, -benzophenoneoxime 2:4:6-trimethylbenzoates are unaffected (by cold aq. EtOH-NaOH), owing to steric hindrance effects; the latter esters are hydrolysed by EtOH-conc. HCl to  $s$ -C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>·CO<sub>2</sub>H and the original COAr<sub>2</sub>. The above production of EtOBz is due to the preliminary addition of EtOH, viz.,  $\text{CAr}_2\text{:N}\cdot\text{OBz} \rightarrow \text{CAr}_2\text{:N}\cdot\text{O}\cdot\text{CPh(OH)(OEt)} \rightarrow \text{CAr}_2\text{:N}\cdot\text{OH} + \text{EtOBz}$ ; this view is confirmed by the formation of  $p$ -C<sub>6</sub>H<sub>4</sub>Ph·CO<sub>2</sub>Me from acetoxime *p*-phenylbenzoate, m.p. 132—133°, and cold aq. MeOH-NaOH.  $\alpha$ -Benzoinoxime 2:4:6-trimethylbenzoate, m.p. about 92° (unstable), is cleaved by aq. 5% NaOH or aq. EtOH-Na<sub>2</sub>CO<sub>3</sub> to PhCHO, PhCN, and  $s$ -C<sub>6</sub>H<sub>2</sub>Me<sub>3</sub>·CO<sub>2</sub>H;  $\beta$ -benzoinoxime 2:4:6-trimethylbenzoate, m.p. 151°, is similarly unaffected, but with aq. EtOH-NaOH the same fission products result. The mechanism of the cleavage process, which is unaffected by steric hindrance, is discussed; it is a modification of that proposed by Mills (Chem. and Ind., 1932, 750) for aldoxime acetates. The above acyl derivatives are all prepared from the requisite oxime and acyl chloride in C<sub>5</sub>H<sub>5</sub>N at room temp.

III. It is suggested (cf. above) that cleavage of acylated  $\alpha$ -benzoinoximes (A), OH·CHPh·CPh·N·O·COR, is a consequence of chelation between the H of the OH and the unshared electron pair on the N; such chelation cannot occur in the  $\beta$ -series owing to the difference in configuration.  $\alpha$ -Benzoinoxime acetate is considered to be chelated since the infra-red absorption curve, compared with that of the  $\beta$ -acetate, shows marked suppression of OH absorption (cf. Hilbert *et al.*, this vol., 703). Examination of the acetates of *o*-hydroxy- and 2-hydroxy-5-methyl-benzophenoneoximes shows that chelation can take place; its occurrence is accompanied by reactions comparable with those of (A). The acetates, m.p. 96—97° (I) and 156° (II), of *syn*-(III) and *anti*-(IV) -*o*-hydroxybenzophenoneoximes (modified prep.; cf. Kohler and Bruce, A., 1931, 732) are hydrolysed by an excess of cold 5% NaOH to (III) and (IV), respectively; with aq. EtOH-Na<sub>2</sub>CO<sub>3</sub>, (I) gives 1-phenylbenzoxazole (V) [i.e., a reaction equiv. to cleavage of (A)], whilst (II) affords (IV). Pyrolysis of (I) in a vac. occurs smoothly and gives 2-phenylbenzisooxazole (VI); (II) similarly undergoes much charring and yields (probably) a little of (V) and (VI) (isolable). The acetate (VII), m.p. 125—126°, of *syn*-2-hydroxy-5-methylbenzophenoneoxime (VIII) (modified prep.) is converted by (a) 5% NaOH into (VIII), (b) aq. EtOH-Na<sub>2</sub>CO<sub>3</sub> into 1-phenyl-4-methylbenzoxazole (IX), and (c) pyrolysis into 2-phenyl-4-methylbenzisooxazole (X), m.p. 92—93°, the acetate (XI), m.p. 157—158°, of *anti*-2-hydroxy-5-methylbenzophenoneoxime (XII), m.p. 136—137°, similarly gives (a) (XII), (b) (XII), and (c) a little of (IX) and (X) (isolable). (XII) is formed when (VIII) is heated with 40% NaOH, whilst (X) is also obtained by successive oximation and action of alkali on the mixture of 2-chloro-5-methyl- and 5-chloro-2-methylbenzophenones prepared (method: Heller, A., 1913,

i, 631) from  $p$ -C<sub>6</sub>H<sub>4</sub>MeCl. (XII) and PCl<sub>5</sub> in Et<sub>2</sub>O give 5:2-OH·C<sub>6</sub>H<sub>3</sub>Me·CO·NHPH.

The infra-red absorption curves for (I) and (VII), unlike those for (II) and (XI) (data now given), do not show OH absorption. (I) and (VII) are much more sol. in CCl<sub>4</sub>, and much less sol. in EtOH, than (II) and (XI). These data show that (I) and (VII) are chelated.

H. B.

**Interconversion of mixed benzoin. H. H. WEINSTOCK, jun., and R. C. FUSON (J. Amer. Chem. Soc., 1936, 58, 1986—1988).**—A difficultly separable equilibrium mixture of 2:4:6- (I) and 2':4':6'- (II) -trimethylbenzoin [mesitylphenyl- and benzoyl-mesityl-carbinol, respectively] is obtained when either (I) or (II) is heated with aq. EtOH-NaOAc. Interconversion probably occurs through the intermediate  $\alpha\alpha'$ -dihydroxy-2:4:6-trimethylstilbene, i.e., the enediol; this view is supported by the following results. (I) and (II) with BzCl in C<sub>5</sub>H<sub>5</sub>N at 80° give a single benzoate, m.p. 127—127.5° [probably that of (I)], hydrolysed (EtOH-KOH) to 2:4:6-trimethylbenzil (III). The Na<sub>2</sub> derivative (IV) from (III) with BzCl affords  $\alpha\alpha'$ -dibenzoyloxy-2:4:6-trimethylstilbene, two forms, m.p. 138.5—139° (V) and 169.5—170° (VI); (V) heated above its m.p. undergoes quant. conversion into (VI), whilst hydrolysis (EtOH-KOH) of (VI) gives (I) and (III). (I) and Ac<sub>2</sub>O-NaOAc for 5 hr. yield the acetate, m.p. 73—73.5°; the same treatment of (II) [and more prolonged treatment of (I)] affords  $\alpha\alpha'$ -diacetoxy-2:4:6-trimethylstilbene, m.p. 104—104.5°, also prepared from (IV) and AcCl. (I) and (II) heated with a little I at 200—220° or in AcOH undergo disproportionation to (III) and Ph 2:4:6-trimethylbenzyl ketone. All reactions are carried out in N<sub>2</sub>. (I) and (II) react with MgMeI in the enediol form to the extent of 78 and 30%, respectively.

H. B.

**Bromination of  $\Delta^5$ -cholestenone dibromide. A. BUTENANDT and G. SCHRAMM (Ber., 1936, 69, [B], 2289—2299).**—Cautious oxidation of cholesterol dibromide (I) with CrO<sub>3</sub> affords  $\Delta^5$ -cholestenone dibromide (II), m.p. 80°, converted by Br<sub>2</sub> (1 mol.) in AcOH into 4:5:6-tribromo- (III), m.p. 106° (decomp.), which is brominated further to 4:4:5:6-tetra-bromo-cholestanone (IV), m.p. 128° (decomp.), also obtained directly from (II). Generally it appears that 3-keto-sterol derivatives in which rings A and B are united in the same manner as in *cis*-decahydronaphthalene are brominated at 4, and those in which the arrangement is as in *trans*-decahydronaphthalene react at 2. It is assumed that the rule can be applied to the determination of configuration, and that rings A and B in (I) are probably united in the *cis*-position. The constitution of (III) rests on the following observations. It is debrominated by Zn and AcOH to  $\Delta^4$ -cholestenone and by NaI in EtOH to a non-cryst. heterogeneous product containing >1 Br per mol. and converted by KOAc in AcOH at 200° into cholestane-3:6-dione. When treated with NaI in EtOH-C<sub>6</sub>H<sub>6</sub> (conc. solu-

tion) (III) gives cholestenedione Et ether; it is therefore stereoisomeric with the  $\text{Br}_3$ -ketone (V) of Inhoffen (this vol., 854, 1104). The structure of (IV) follows from its transformation by KOAc in BuOH into  $\Delta^5$ -cholestene-3:4-dione, m.p.  $159^\circ$  (quinoxaline derivative, m.p.  $175^\circ$ ), the constitution of which (cf. Inhoffen, *loc. cit.*) is confirmed by its oxidation to the 7-keto-dicarboxylic acid,  $\text{C}_{27}\text{H}_{42}\text{O}_5$ , m.p.  $215$ — $216^\circ$ . The possibility of confirming the constitution

(IV) by its production by bromination of (V) is excluded since the latter is transformed by Br in AcOH or  $\text{Et}_2\text{O}$  into an  $\alpha\beta$ -unsaturated  $\text{Br}_3$ -ketone (VI), m.p.  $163^\circ$ , also obtained from (IV) in warm EtOH. Further proof of the structure of (IV) is afforded

by its transformation by NaI in boiling abs. EtOH into 4-bromo-6-ethoxy- $\Delta^4$ -cholesten-3-one, m.p.  $110$ — $111^\circ$  (decomp.), and thence by KOAc in boiling BuOH into cholestenedione Et ether.

H. W.

**Constitution of benzoylformoin.** R. SCHOLL (Ber., 1936, 69, [B], 2288; cf. this vol., 606).—The lactol ether formula of benzoylformoin has been advanced previously by Blatt (A., 1935, 982).

H. W.

**So-called "valency tautomerism" of unsaturated systems.** B. EISTERT (Ber., 1936, 69, [B], 2393—2398).—An explanation of the constitution of tetraphenyldimethylenediphenoquinone, tetraarylnodimethanes, and 4:4'-disubstituted dipyrindyls along the lines of mesomerism is advanced; this harmonises with Müller's magneto-chemical observations.

H. W.

**Reduction potential of some naphthaquinones.**—See this vol., 1467.

**Preparation of fluoroaminoanthraquinone.**—See B., 1936, 1083.

**Linear pentacene.** C. MARSCHALK (Bull. Soc. chim., 1936, [v], 3, 2155—2158; cf. this vol., 1256).—6:13-Dihydroxypentacene-5:14:7:12-diquinone (I) is obtained by cyclisation of 1:4-dihydroxy-2-benzoylanthraquinone-3-carboxylic acid (obtained by condensation of 1:4-dihydroxyanthraquinone-2:3-dicarboxylic anhydride with  $\text{C}_6\text{H}_6$  and  $\text{AlCl}_3$ ), by cautious oxidation of the substance (II) obtained (*loc. cit.*) from  $o\text{-C}_6\text{H}_4(\text{CO})_2\text{O}$  and leucoquinizarin, and by oxidation of the Ac derivative of (II) with  $\text{PbO}_2$  or  $\text{CrO}_3$  in boiling AcOH and hydrolysis of the product. (II) is therefore 5:6:13:14-tetrahydroxypentacene-7:12-quinone. The relationship between (I) and (II) is similar to that between quinone and quinol. Oxidation of (I) or (II) by  $\text{Pb}(\text{OAc})_4$  in AcOH at  $50$ — $60^\circ$  gives pentacene-5:14:6:13:7:12-triquinone, reduced by  $\text{N}_2\text{H}_4$  or  $\text{Na}_2\text{S}_2\text{O}_4$  to (II), by  $\text{SO}_4$  to (II) and then to (I) by KI in cold AcOH to (I).

H. W.

**Comparison of the rate of racemisation with the rate of enolisation [of *l*-menthyl *d*- $\alpha$ -phenylacetoacetate].** R. H. KIMBALL (J. Amer. Chem. Soc., 1936, 58, 1963—1970; cf. Rupe *et al.*, A., 1913, i, 266, 884).—The pseudo-unimol. velocity coeffs. for (i) the racemisation (of Cx) and (ii) the enolisation of *l*-menthyl *d*- $\alpha$ -phenylacetoacetate (I) in cyclohexane (in which enolisation is 71% complete at

equilibrium) containing 8—12 p.p.m. of piperidine are determined polarimetrically and by direct Br-titration, respectively; (i) proceeds several times as fast as (ii). Polarimetric determination of the rate for *d*-keto  $\rightarrow$  enol gives a val.  $>$  that obtained by titration, indicating that enolisation proceeds through an intermediate (II) (which subsequently changes partly to the enol and partly to the *dl*-keto-form). (II) may be the intermediate anion which has lost its asymmetry; alternatively, reversible formation of a little open-chain enol, followed by a slower accumulation of chelated enol, may occur.

(I), prepared from *l*-menthol and  $\text{CHPhAc}\cdot\text{CO}_2\text{Et}$  (improved prep.) at  $150$ — $160^\circ$  followed by distillation and slow evaporation of a MeOH-solution of the resulting oil, has m.p.  $77$ — $78.3^\circ$  (in Pyrex glass) (lit.  $69^\circ$ ),  $[\alpha]_D^{25}$  (in cyclohexane)  $-15.84^\circ \rightarrow -59.83^\circ$ ,  $[\alpha]_{5461} + 21.9^\circ$  in MeOH (cf. *loc. cit.*). Equilibration of (I) with a trace of  $\text{Ba}(\text{OH})_2$  and subsequent slow distillation (Hickman mol. still) at  $85$ — $95^\circ$  gives a product (64% enol), which on repeated fractionation in absence of catalyst affords a const.-boiling mixture containing 93.8% of enol. The pure enol (*i.e.*, menthyl  $\beta$ -hydroxy- $\alpha$ -phenylcrotonate) is calc. to have  $[\alpha]_D^{25} -56.5^\circ$  in cyclohexane.

H. B.

[True constitution of camphenilyl and 4-methylcamphenilyl chloride.] P. LIPP and J. DANIELS (Ber., 1936, 69, [B], 2251—2252).—Difficulties in conception of the structure of camphenilyl chloride are removed by considering that it,  $\alpha$ - and  $\beta$ -fenchocamphoryl chloride are to one another in the relationship of an equilibrium isomerism (cf. Komppa *et al.*, this vol., 1258).

H. W.

**Benzylidenecamphane**, a product of the dehydration of tertiary benzylbornyl alcohol. S. S. NAMETKIN and M. K. STRUGAZKI (Ber., 1936, 69, [B], 2272—2277).—The main product of the dehydration of benzylbornyl alcohol by  $\text{KHSO}_4$ , aq. and anhyd.  $\text{H}_2\text{C}_2\text{O}_4$ ,  $\text{HCO}_2\text{H}$ , 50%  $\text{H}_2\text{SO}_4$ , or anhyd.  $\text{CuSO}_4$  is the cryst. hydrocarbon, m.p.  $25^\circ$ , which, contrary to Haller and Bauer (A., 1906, i, 440), is identified as benzylidenecamphane,

$\text{C}_8\text{H}_{14}$   since it is oxidised by  $\text{KMnO}_4$  to camphor, camphoric acid, and BzOH. It is indifferent towards AcOH and  $\text{CCl}_3\cdot\text{CO}_2\text{H}$ . It is obtained synthetically from phenylbornylcarbinol, b.p.  $169$ — $170^\circ/15$  mm. (prep. from Mg bornyl chloride and PhCHO), which is treated with K in dry PhMe followed successively by  $\text{CS}_2$  and MeI and decomp. of the ester so produced.

H. W.

**Stereoisomerism in the fenchol series.** H. SCHMIDT and L. SCHULZ (Ber. Schimmel, 1935, 97—99; Chem. Zentr., 1936, i, 350—351).—As in the borneol series there are two stereoisomeric optically inactive fenchyl alcohols which, on oxidation, give rise to only one *dl*-fenchone. Hydrogenation (Ni) of *dl*-fenchone yields *dl*- $\beta$ -fenchyl alcohol, b.p.  $200.5^\circ/750$  mm., f.p.  $6.3^\circ$  (formate; acetate; phenylurethane, m.p.  $90$ — $90.5^\circ$ ; *H* phthalate, m.p.  $153$ — $153.5^\circ$ ). *dl*- $\alpha$ -Fenchyl alcohol, prepared by reduction of *dl*-fenchone with Na-EtOH, has m.p.  $38^\circ$ , b.p.  $199.5^\circ/750$  mm. (phenylurethane, m.p.  $104^\circ$ ; *H* phthalate, m.p.  $169^\circ$ ). The following are obtained

similarly: *l*- $\alpha$ -fenchyl alcohol (from *d*-fenchone), m.p. 48°,  $[\alpha]_D^{20}$  -11° in EtOH; *d*- $\alpha$ -fenchyl alcohol (from *l*-fenchone), m.p. 47°,  $[\alpha]_D^{20}$  +11.5° in EtOH (*phenylurethane*, m.p. 81°; *H phthalate*, m.p. 145.5°); *l*- $\beta$ -fenchyl alcohol (from *d*-fenchone), m.p. 5–6°, b.p. 200.5°/750 mm.,  $[\alpha]_D^{20}$  -21.7° in EtOH (*phenylurethane*, m.p. 89–90°); *d*- $\beta$ -fenchyl alcohol (from *l*-fenchone),  $[\alpha]_D^{20}$  +21.8° in EtOH (*phenylurethane*, m.p. 89°; *H phthalate*, m.p. 151°). By analogy with borneol,  $\alpha$ -fenchyl alcohol is assigned the *exo*- and  $\beta$ -fenchyl alcohol the *endo*-configuration.

H. N. R.

**Degradation of fenchone in the animal organism.** F. REINARTZ and W. ZANKE (Ber., 1936, 69, [B], 2259–2262).—*d*-Fenchone is administered to dogs and the paired glycuronic acid is separated from the urine as the Pb salt, which is treated with 15%  $H_2SO_4$ ; the filtrate from the  $PbSO_4$  is boiled with  $H_2O$ , thereby giving a mixture (I) of hydroxyfenchones which could not be separated into its components by crystallisation or through the *p*-nitrobenzoates. (I) is therefore oxidised with  $CrO_3$  followed by  $KMnO_4$ , thus giving 5-ketofenchone, m.p. 36°, Rimini's 4-hydroxyfenchone, m.p. 79–80° (3:5-dinitrobenzoate, m.p. 144–146.5°), and  $\alpha$ -apofenchone-3-carboxylic acid, m.p. 120.5–122° (*Ag* salt), decarboxylated to fenchosantenone. 5-Ketofenchonedisemicarbazone has m.p. 243.5°.

H. W.

**$\beta$ -Myrcene.** Reduction with sodium and alcohol. G. DUPONT and V. DESREUX (Compt. rend., 1936, 203, 623–625).— $\beta$ -Myrcene, b.p. 72–73°/25 mm., free from  $\alpha$ -myrcene, with Na in EtOH affords a  $H_2$ -derivative (I), b.p. 62–63°/18–20 mm. (cf. A., 1901, i, 732), apparently identical with a reduction product (II) of  $\beta$ -geraniol. The Raman spectrum of (I) exhibits a line of frequency 1648  $cm^{-1}$ , not shown by (II), probably due to a terminal double linking. It is probable that reduction at the linking outside the conjugated system in  $\beta$ -myrcene is a less marked subsidiary reaction and may account for the marked differences in the physical consts. of (I) and (II) (cf. A., 1929, 538).

J. L. D.

**Polyterpenes and polyterpenoids. CVII.** Transformation of gypsogenin (alsapogenin) into oleanolic acid. L. RUZICKA and G. GIACOMELLO (Helv. Chim. Acta, 1936, 19, 1136–1140).—Fractional crystallisation of crude gypsogenin gives a product, m.p. about 270°, which does not appear homogeneous under the fluorescence microscope and gives analytical data in harmony with a  $C_{30}$  formula. It is converted by boiling  $Ac_2O$  and  $NaOAc$  into a more freely sol. acetate (I),  $C_{32}H_{48}O_5$ , m.p. 176–177°,  $[\alpha]_D^{20}$  +78° in  $CHCl_3$ , and a more sparingly sol. acetate,  $C_{32}H_{48}O_5$ , m.p. 262°,  $[\alpha]_D^{20}$  +65° in  $CHCl_3$ , (I) gives a yellow colour with  $C(NO_2)_4$ , is converted by  $CH_2N_2$  in  $Et_2O$  into the *Me* ester,  $C_{33}H_{50}O_5$ , m.p. 186°, and by Br in  $MeOH-CHCl_3$  into the *Br*-lactone,  $C_{32}H_{47}O_5Br$ , m.p. 180–181° (decomp.). The semicarbazone, m.p. (indef.) 140–160° and m.p. 274° (decomp.) after re-solidification, is transformed by  $NaOEt$  in EtOH at 160–170° into oleanolic acid, m.p. 304–306°,  $[\alpha]_D^{20}$  +76.9° in  $CHCl_3$ .

H. W.

**Helenalin.** I. Helenalin, the bitter sternutative substance occurring in *Helenium autumn-*

*nale*. E. P. CLARK (J. Amer. Chem. Soc., 1936, 58, 1982–1983).—Details are given for the isolation of helenalin,  $C_{15}H_{18}O_4$ , m.p. 167°,  $[\alpha]_D^{20}$  -101.9° in 95% EtOH (*Ac*, m.p. 184°, and *methoxyacetyl*, m.p. 135°, derivatives; *dibromide*, 161°), which is reduced ( $H_2$ ,  $PtO_2$ ,  $EtOAc$ ) to tetrahydrohelenalin, m.p. 176° (*Ac* derivative, m.p. 145°).

H. B.

**Constituents of pyrethrum flowers. IV. Semicarbazones of pyrethrins I and II and of pyrethrolone.** H. L. HALLER and F. B. LAFORGE (J. Org. Chem., 1936, 1, 38–51; cf. A., 1935, 1550).—Pyrethrin I concentrate (45% of I and 14% of II) gives, best in  $C_6H_5N$ , the nearly pure I-semicarbazone, m.p. about 118° (in  $CCl_4$  gives a new compound), which affords by hydrolysis with aq.  $H_2C_2O_4$  about 30% of pyrethrin I, partly changed by distillation at 175–180°/2 mm. A pyrethrin II concentrate (81% of II) gives, best in  $C_6H_5N$ , the II-semicarbazone, m.p. 164–165°, hydrolysed by aq.  $H_2C_2O_4$  to free II (30% yield), which is highly toxic to flies and decomposes when distilled in a vac., giving thereafter a poor yield of a different semicarbazone. Pyrethrolonesemicarbazone (A),  $C_{12}H_{17}O_2N_3$  (lit.  $H_{19}$ ), m.p. 208° (decomp.), is obtained from pyrethrolone (B) or the I- or II-semicarbazones and  $NaOMe$ . The II-semicarbazone with  $H_2-PtO_2$  in  $EtOAc$  gives a tetrahydro-semicarbazone,  $C_{23}H_{35}O_5N_3$ , m.p. 141–142° (also obtained by hydrogenation of free II), which with  $NaOMe$  affords tetrahydropyrethrolonesemicarbazone,  $C_{12}H_{21}O_2N_3$ , m.p. 196° (decomp.), also obtained by hydrogenation (4 H absorbed) of (A). The formula of (B) thus is revised. Chrysanthemum acid is best characterised by its *p*-phenylphenacyl, m.p. 65°, chrysanthemumdicarboxylic acid by its *di*-*p*-phenylphenacyl ester, m.p. 154°.

R. S. C.

**Constituents of lichens found in Ireland. Buellia canescens.** II. P. A. SPILLANE, J. KEANE, and T. J. NOLAN (Sci. Proc. Roy. Dublin Soc., 1936, 21, 333–343; cf. A., 1935, 133).—A compound,  $C_{15}H_8O_5Cl_3 \cdot OMe$ , m.p. 257°, is isolated in small amount from *B. canescens* (I). The ratio of chlorinated to unchlorinated atranorin varies in different lichens, being 9:1 in (I), 4:1 in *Lecanora gangaleoides*, and 35:65 in *L. sordida*. The difficulty of determining OMe in lichen products is confirmed. Diploicin (II),  $OH \cdot C_{15}H_6O_3Cl_4 \cdot OMe$  (*K* salt), with  $CH_2N_2$  gives an ether,  $C_{15}H_6O_3Cl_4(OMe)_2$ , m.p. 220°, which with  $KOH-MeOH$  gives the phenolic ester,  $OH \cdot C_{14}H_6OCl_4(OMe)_2 \cdot CO_2Me$ , m.p. 143°, sol. in 2% aq.  $KOH$ . With  $KOH-MeOH$  (II) affords the phenolic ester,  $OMe \cdot C_{14}H_6OCl_4(OH)_2 \cdot CO_2Me$ , m.p. 200°, which with  $CH_2N_2$  gives the ether,  $C_{14}H_6OCl_4(OMe)_3 \cdot CO_2Me$ , m.p. 97°, hydrolysed by 15%  $KOH-MeOH$  to the acid,  $C_{14}H_6OCl_4(OMe)_3 \cdot CO_2H$ , m.p. 160–161°. (II) is probably as annexed.

R. S. C.

**Yellow pigment from Sake-Kasu (sake grains).** T. HIGASHI (Bull. Inst. Phys. Chem. Res. Japan, 1936, 15, 1060–1076).—*Flazine* (I),  $C_{18}H_{16}O_5N_2$ , m.p. 218–220° (decomp.) [*hydrochloride*, + $H_2O$ ; *hydr-*

iodide, unstable; (?)  $\text{NO}_2$ -derivative,  $\text{C}_{17}\text{H}_{13}\text{O}_5\text{N}_2\cdot\text{NO}_2\cdot\text{H}_2\text{O}$ , is isolated in 0.001% yield from sake grains. In EtOH,  $\text{COMe}_2$ , or acid it shows a strong yellow-green fluorescence, destroyed by alkali. (I) resinifies in air and resembles lactoflavin, but has less vitamin- $\text{B}_2$  activity. Absorption spectra, reduction potential, and fluorescence indicate phenazine structure. On oxidation (I) gives a substance,  $\text{C}_{17}\text{H}_{12}\text{O}_5\text{N}_2$ , and on dehydration a substance,  $\text{C}_{36}\text{H}_{30}\text{O}_9\text{N}_4$ . R. F. P.

**Hydrogenation value of violaxanthin.** P. KARRER and U. SOLMSEN (Helv. Chim. Acta, 1936, 19, 1024—1025).—Hydrogenation of purified violaxanthin in AcOH or EtOH-AcOH causes absorption of 9.5—10  $\text{H}_2$ . It therefore contains 10 rather than 11 double linkings. This harmonises with spectroscopic evidence which is compatible with the presence of 11 double linkings only if two ethylenic linkings are assumed to be outside conjugation. H. W.

**Bitter principles of Colombo root.** IV. **Hydrogenation of columbin and isocolumbin.** F. WESSELY, A. MUNSTER, and K. SCHONOL [with, in part, W. ISEMAN] (Monatsh., 1936, 68, 313—325; cf. this vol., 610, 995).—Columbin (I) (improved isolation),  $[\alpha]_D +52.2^\circ$ , is  $\text{C}_{10}\text{H}_{22}\text{O}_6$ ; decarboxycolumbin (II),  $\text{C}_{19}\text{H}_{22}\text{O}_4$ , has m.p. 148—149°. Hydrogenation (Pd-sponge in MeOH) of (I) gives a product in which the second group of (I) which reacts with hot alkali is not present. Reaction is not accompanied by loss of  $\text{CO}_2$ , and gives mainly a mixture of stereoisomeric octahydrocolumbic acids (III) which could not be obtained cryst., but from which after treatment with  $\text{CH}_2\text{N}_2$  a cryst. Me ester, m.p. 124—131°,  $[\alpha]_D -18.7^\circ$ , is isolated and a neutral product,  $\text{C}_{20}\text{H}_{28}\text{O}_6$ , probably a mixture of saturated lactones. The view that 2 O of the 6 O of (I) are present in a normal lactone ring containing at least one double linking is confirmed, but the hypothetical presence of a second lactone ring is discarded, particularly in view of the behaviour of (III) towards Zerevitinov's reagent. Hydrogenation of (II) gives a mixture of stereoisomeric octahydrodecarboxycolumbic acids. Hydrogenation establishes that (I) contains three double linkings, whereas in (III) 2 O and O are present in  $\text{CO}_2\text{H}$  and OH, respectively, and the function of the remaining 3 O is unknown. isocolumbin is hydrogenated to a non-cryst. mixture of stereoisomeric acids from which a non-homogeneous, cryst. Me ester is isolated which contains 1 OH (Zerevitinov). H. W.

**Reaction of lignin and vanillin.** P. FOURMENT and H. ROQUES (Bull. Sci. pharmacol., 1935, 42, 449—451; Chem. Zentr., 1936, i, 601).—Vanillin, in addition to plant tissues containing lignin, gives a red coloration with benzidine in AcOH solution.

H. N. R.  
**Lignin.** VIII. **Thioglycollic acid as a reagent for lignin.** B. HOLMBERG (Ing. Vet. Akad. Handl. No. 131, 81 pp.); Chem. Zentr., 1936, i, 93—94).—In presence of acid lignin combines with thioglycollic to give a sparingly sol. compound. Application of this reaction to a no. of plant species is described. A. G. P.

**Hydroxyfurans.** II. **3-Hydroxy-2:5-diphenylfuran.** E. P. KOHLER and D. W. WOODWARD (J. Amer. Chem. Soc., 1936, 58, 1933—1936).—Successive treatment of 3-acetoxy-2:5-diphenylfuran (I) (Lutz, A., 1927, 61) with  $\text{MgMeI}$  and cold dil.  $\text{H}_2\text{SO}_4$  gives 3-hydroxy-2:5-diphenylfuran (II) (not isolable), which resembles the 2:4:5- $\text{Ph}_3$  derivative (this vol., 479). (II) (in  $\text{Et}_2\text{O}$ ) and  $\text{O}_2$  afford the 2:3-peroxide, explodes about  $100^\circ$ , which is reduced by AcOH-KI to 3:3'-diketo-2:5:2':5'-tetraphenyl-2:3:2':3'-tetrahydro-2:2'-difuryl, m.p.  $255^\circ$ , and catalytically to  $\alpha\beta\delta$ -triketo- $\alpha\delta$ -diphenylbutane (Lutz et al., A., 1934, 1222). Hydrolysis (dil.  $\text{H}_2\text{SO}_4$  in AcOH and  $\text{N}_2$ ) of (I) gives the unstable 3-keto-2:5-diphenyl-2:3-dihydrofuran, m.p.  $93^\circ$ , i.e., the ketonic form of (II). (I) and  $\text{Cl}_2$  or  $\text{PCl}_5$  afford 2-chloro-3-keto-2:5-diphenyl-2:3-dihydrofuran (III), m.p.  $133^\circ$  (the 2-Br-derivative has m.p.  $135^\circ$ ), converted by boiling MeOH and EtOH into the 2-OMe- and 2-OEt-derivatives [cf. Lutz et al. (loc. cit.)], who formulate them as open-chain compounds]. Maleic anhydride, PhBr, and  $\text{AlBr}_3$  in  $\text{C}_2\text{H}_5\text{Br}_4$  at  $<50^\circ$  give  $\beta$ -p-bromobenzoylacrylic acid, m.p.  $161^\circ$ , the chloride, m.p.  $103^\circ$ , of which with  $\text{C}_6\text{H}_6$  and  $\text{AlCl}_3$  in  $\text{N}_2$  affords  $\alpha$ -benzoyl- $\beta$ -p-bromobenzoyl ethylene, m.p.  $127^\circ$ , also obtained from  $\text{COPh}\cdot\text{CHO}$  and p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{COMe}$  in  $\text{Ac}_2\text{O}$ . This and Br in  $\text{CHCl}_3$  yields dibromides, m.p.  $116$ — $119^\circ$  and  $170$ — $175^\circ$  (decomp.), a mixture of which is converted by MeOH-KOH, followed by MeOH-HCl, into 3-keto-2-methoxy-2-phenyl-5-p-bromophenyl- (IV), m.p.  $158^\circ$ , and 5-phenyl-2-p-bromophenyl- (V), m.p.  $102^\circ$ , -2:3-dihydrofurans. (IV) (ozonolysis products, p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{CO}_2\text{H}$  and MeOBz) is hydrolysed (MeOH-KOH) to  $\alpha\beta\delta$ -triketo- $\alpha$ -phenyl- $\delta$ -p-bromophenylbutane, m.p.  $100$ — $101^\circ$  [oxidised (30%  $\text{H}_2\text{O}_2$ , MeOH-KOH) to p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{COMe}$ , p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{CO}_2\text{H}$ , and BzOH], whilst (V) (ozonolysis products (p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{CO}_2\text{Me}$  and BzOH) similarly gives  $\alpha\beta\delta$ -triketo- $\delta$ -phenyl- $\alpha$ -p-bromophenylbutane, m.p.  $88$ — $90^\circ$  (oxidised to  $\text{COPhMe}$ , BzOH, and p- $\text{C}_6\text{H}_4\text{Br}\cdot\text{CO}_2\text{H}$ ). The 3:4-diacetoxy- and 3-chloro-4-acetoxy-2:5-diphenylfurans of Lutz et al. (loc. cit.) are 3-keto-2-acetoxy-2:5-diphenyl-2:3-dihydrofuran, m.p.  $140^\circ$ , and (III), respectively; the  $\alpha$ -chloro- $\gamma\delta$ -diketo- $\alpha\delta$ -diphenyl- $\Delta^2$ -butene of Lutz and Wilder (A., 1934, 1361) is also (III). H. B.

**Hydrazide and azide of 3:4-dihydroxyfuran-2:5-dicarboxylic acid.** A. DARAPSKY and M. STAUBER (J. pr. Chem., 1936, [ii], 146, 209—218).—Treatment of  $\text{Me}_2$  3:4-dihydroxyfuran-2:5-dicarboxylate (I) with  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  in EtOH gives the dihydrazine salt,  $\text{C}_8\text{H}_8\text{O}_7\cdot\text{N}_2\text{H}_4$ , m.p. (indef.)  $168^\circ$  (decomp.). With boiling  $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$  (I) yields the monohydrazine salt, decomp.  $>200^\circ$ , of 3:4-dihydroxyfuran-2:5-dicarbonyldihydrazide, m.p.  $>260^\circ$  after darkening at  $200^\circ$  [dihydrochloride, blackens at  $260^\circ$  after becoming discoloured at  $170$ — $220^\circ$ ; dipicrate, gradual decomp. at about  $205^\circ$  after becoming brown at  $180^\circ$ ; dibenzylidene, m.p.  $258^\circ$  (decomp.), di-o-hydroxybenzylidene, m.p.  $>270^\circ$ , dicinnamylidene, m.p.  $240^\circ$  (decomp.), and diisopropylidene, blackens at  $260^\circ$  after darkening at  $170$ — $220^\circ$ , derivatives]. 3:4-Dihydroxyfuran-2:5-dicarbonyldiazide (II), explodes at  $148$ — $149^\circ$ , is transformed by  $\text{NH}_2\text{Ph}$  in

boiling  $\text{Et}_2\text{O}$  into the salt,  $\text{C}_6\text{H}_2\text{O}_5\text{N}_6\text{NH}_2\text{Ph}$ , and by  $\text{NH}_2\text{Ph}$  at  $150^\circ$  into the *dianilide*, m.p.  $>260^\circ$ . The azide is converted by boiling  $\text{EtOH}$  into 3:4-*dihydroxyfuran-2:5-diurethane*, m.p. 147, which could not be transformed by heat into the desired dilactone

When warmed in indifferent media (II) evolves  $\text{N}_2$  and yields a solid tile-red compound which could not be purified; analyses indicate the presence of the dicarbimide but the material is odourless and does not react with  $\text{EtOH}$  so that possibly (III) is present. Attempts to hydrogenate (I) by  $\text{H}_2$ -colloidal Pd, Na-Hg, Al-Hg, or Na in boiling  $\text{EtOH}$  were unsuccessful.

(III.)

H. W.

**Electrolysis of aromatic acids. II.** Electrolysis of opianic acid. V. M. RODIONOV and V. C. ZVORYKINA (Bull. Soc. chim., 1936, [v], 3, 1836—1841; cf. this vol., 722).—Electrolysis of K opianate yields meconine, a mixture of dimeconyls, m.p. 215—230°, and resins. In a cell with diaphragm the reduction products are obtained in the cathodic division in better yield; opianic acid under the same conditions gives less impure products, without resins. Reduction by Na-Hg gives meconine and a trace of  $\alpha$ -dimeconyl. Mixed dimeconyls electrolysed, or reduced by Na-Hg, give a substance, m.p. 170—172°.

E. W. W.

**Synthesis of dehydracetic acid from ethyl acetoacetate.** F. ARNDT, B. EISTERT, H. SCHOLZ, and E. ARON (Ber., 1936, 59, [B], 2373—2380).—Irregularities in the conversion of  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  into dehydracetic acid (I) (Arndt *et al.*, A., 1924, i, 1223) are traced to the influence of the containing vessel. The initial stage is the formation of  $\text{EtOH}$  and  $\text{CO}_2\text{Et}\cdot\text{CH}\cdot\text{CMe}\cdot\text{O}\cdot\text{CO}\cdot\text{CH}_2\text{Ac}$  the progress of which depends on the continuous removal of  $\text{EtOH}$  [very little (I) is produced when  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  is heated (sealed) at  $<$  its b.p.]; this is followed by an irreversible Claisen condensation for which the presence of alkali is required. This is provided uncertainly by the alkali of the glass, and is best supplied by  $\text{NaHCO}_3$  in controlled amount, since the decomp. of  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  into  $\text{COMe}_2$  is also accelerated thereby. The best yields are obtained with minute amounts of catalyst if the process is interrupted when about 25% of the possible  $\text{EtOH}$  has distilled; unchanged ester is distilled from the product and worked up as a fresh charge. At 300—600° the streaming vapours of  $\text{CH}_2\text{Ac}\cdot\text{CO}_2\text{Et}$  are remarkably stable in presence of  $\text{SiO}_2$ , Al, Cu, or V2A steel. Fe accelerates decomp. into  $\text{COMe}_2$ ,  $\text{CO}_2$ , gaseous and resinous products. In absence of Fe, glass or porcelain, preferably in tubes of the same material, gives good yields of pure (I) if the temp. is  $>400^\circ$ . The operation may be extended over long periods and 25% conversion is secured. The process appears generally applicable for the production of "dehydroacids" from  $\beta$ -CO-esters. Thus  $\text{CH}_2\text{Bz}\cdot\text{CO}_2\text{Et}$  gives dehydrobenzoylacetic acid,  $\text{CPh} \begin{array}{c} \diagup \text{CH}\cdot\text{CO} \\ \diagdown \quad \diagup \\ \text{O} \quad \text{CO} \end{array} \text{CHAc}$ , m.p. 171°, converted by  $\text{H}_2\text{SO}_4$  at 138—140° into  $\text{BzOH}$  and 6-phenylpyronone, decomp. 245—246°, which with

$\text{NH}_3\cdot\text{H}_2\text{O}$  at  $120^\circ$  affords 2:4-dihydroxy-6-phenylpyridine, decomp. 315—318°. An improved prep. of 2:6-dimethylpyrone from (I) is described. Short treatment of (I) with 90%  $\text{H}_2\text{SO}_4$  at  $135^\circ$  gives 6-methylpyronone or 6-methyl-4-hydroxy-2-pyrone (II), converted by  $\text{NH}_2\text{Me}\cdot\text{H}_2\text{O}$  at  $130^\circ$  into 4-hydroxy-1:6-dimethyl-2-pyridone, decomp. 225—226°; 4-hydroxy-6-methyl-1-ethyl-2-pyridone, decomp.  $198^\circ$ , is obtained with  $\text{NH}_2\text{Et}$ . 4-Hydroxy-1-cyclohexyl-6-methyl-2-pyridone has m.p.  $108^\circ$ . (II), boiling 10N-NaOH, and  $p\text{-NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2\cdot\text{H}_2\text{SO}_4$  yield 4-hydroxy-1-p-dimethylaminophenyl-6-methyl-2-pyridone, decomp. 270—275°, whereas  $\text{NH}_2\text{Ph}$  yields a substance, m.p. 199—200°, of undetermined structure. H. W.

**Geometrical inversion in the acids derived from the coumarins. III.** *Trans-* to *cis-*. T. R. SESHADRI and P. S. RAO (Proc. Indian Acad. Sci., 1936, 4, A, 157—161; cf. A., 1935, 211).— $\text{HgO}$  lowers the temp. of decomp. of coumaric (I), 4-methyl- (II) and 5-nitro-coumaric acid (III) to give the coumarin in  $>50\%$  yield. Similarly, with  $\text{HgCl}_2$  coumarins are formed in excellent yield; in each case the coumarin mercurichloride is isolated. (I) and (II) with conc.  $\text{H}_2\text{SO}_4$  at  $100^\circ$  give poor yields of the coumarin due to sulphonation, whereas (III) gives a 95% yield; boiling  $\text{EtOH}$  containing dry  $\text{HCl}$  decarboxylates (I) and (II) and esterifies (III).

J. L. D.

**Reactivity of the double linking in coumarins and related  $\alpha\beta$ -unsaturated carbonyl compounds. II.** Action of mercury salts on coumarins. T. R. SESHADRI and P. S. RAO (Proc. Indian Acad. Sci., 1936, 4, A, 162—169; cf. A., 1928, 298).—Coumarin with boiling  $\text{MeOH}$  containing  $\text{Hg}(\text{OAc})_2$  in excess affords 3:6:8-triacetoxymercuri-4-methoxymelilotic anhydride, converted by  $\text{H}_2\text{S}$  in  $\text{NaOH}$  into  $\beta$ -methoxymelilotic acid, m.p.  $122\text{—}123^\circ$  (cf. A., 1912, i, 461), and with  $\text{Br}$  in  $\text{AcOH}$  gives 3:6:8-tribromocoumarin. Similarly, 7-methylcoumarin affords 3:6:8-triacetoxymercuri-4-methoxy-7-methylmelilotic anhydride, decomp. at  $265^\circ$ , converted by  $\text{H}_2\text{S}$  in  $\text{NaOH}$  into 4-methylcoumaric acid, and with  $\text{Br}$  in  $\text{AcOH}$  affords 3:6:8-tribromo-7-methylcoumarin, m.p. 207—208°. 6-Nitrocoumarin similarly yields 3:8-diacetoxymercuri-6-nitro-4-methoxymelilotic anhydride, converted by  $\text{H}_2\text{S}$  in  $\text{NaOH}$  into 5-nitrocoumaric acid, and by  $\text{Br}$  in  $\text{AcOH}$  into 3:8-dibromo-6-nitrocoumarin (cf. J.C.S., 1923, 123, 3380). Coumarin and 7-methylcoumarin with  $\text{HgCl}_2$  in  $\text{COMe}_3$  afford 3-chloromercuri-4-chloro- (cf. *ibid.*, 1908, 93, 524) and 7-methyl-melilotic anhydride, respectively, decomposed by  $\text{H}_2\text{S}$  in  $\text{NaOH}$  into coumaric and 4-methylcoumaric acid, respectively. 6-Nitrocoumarin does not react with  $\text{HgCl}_2$ .

J. L. D.

**Separation of natural mixtures of anthocyanins by chromatographic adsorption analysis. II.** "Althæin." P. KARRER and H. M. WEBER (Helv. Chim. Acta, 1936, 19, 1025—1027; cf. this vol., 341).—Chromatographic analysis, using  $\text{CaSO}_4\cdot 2\text{H}_2\text{O}$ , shows that althæin (Willstätter *et al.*, A., 1915, i, 287) is a mixture of monoglucosides of delphinidin 3':5'- $\text{Me}_2$  ether (syringidin), delphinidin 3'- $\text{Me}$  ether, and delphinidin. H. W.

**Pigment of the corn poppy (*Papaver rhæas*, L.).** See this vol., 1572.

**Anthocyanin pigment of the winesap apple.**—See this vol., 1435.

**Constituents of the Chinese drug lei-kung-teng.**—See this vol., 1572.

**Constitution of cubebin.** R. D. HAWORTH and W. KELLY (Chem. and Ind., 1936, 901—902).—The structure  $\begin{array}{c} \text{CHX}-\text{R} \\ \text{CHX}-\text{CH}_2 \end{array} > \text{O}$  ( $\text{X} = 3:4\text{-CH}_2\text{O}_2\text{:C}_6\text{H}_3\text{:CH}_2\text{:}$ ;  $\text{R} = \text{CH}\cdot\text{OH}$ ) for cubebin (Ishiguro, this vol., 1247) is confirmed by the presence of 1 OH (Zerevitinov), semicarbazone formation, and facile oxidation to cubebinolide ( $\text{R}-\text{CO}$ ). J. W. B.

**Vegetable heart poisons. XI. Constitution of thevetin.** R. TSCHESCHE (Ber., 1936, 69, [B], 2368—2372).—Thevetin (I), gradual decomp.  $>195^\circ$ , obtained from be-still nuts (Chen *et al.*, A., 1934, 820) when dried at  $100^\circ/10$  mm. has the composition  $\text{C}_{42}\text{H}_{66}\text{O}_{18}\cdot 0.5\text{H}_2\text{O}$ , which becomes  $\text{C}_{42}\text{H}_{66}\text{O}_{18}\cdot 3\text{H}_2\text{O}$  when the product is exposed to air. It is converted by boiling  $0.1N\text{-KOH-MeOH}$  into *isothevetin*,  $\text{C}_{42}\text{H}_{66}\text{O}_{18}\cdot 2\text{H}_2\text{O}$ , m.p.  $236\text{--}238^\circ$ . Complete hydrolysis of (I) is difficult, and energetic treatment with acids causes separation of 2 mols. of glucose originally present as gentiobiose, since the octa-acetate is obtained when (I) is treated with  $\text{Ac}_2\text{O}$  and  $\text{ZnCl}_2$  at  $70^\circ$ . A third sugar mol., probably digitalose, is present as a Me ether, but its separation from the aglucone requires so drastic treatment that the mol. is disrupted. Cautious hydrolysis of (I) with  $2N\text{-HCl}$  in  $\text{H}_2\text{O-EtOH}$ , hydrogenation of the residue ( $\text{PtO}_2$  in  $\text{AcOH}$ ), and renewed hydrolysis of the product leads to tetrahydroanhydrothevetigenin (II), oxidised by  $\text{CrO}_3$  to tetrahydroanhydrodigitoxigenone, m.p.  $245\text{--}248^\circ$ ,  $[\alpha]_D^{20} +35.8^\circ$  in  $\text{CHCl}_3$ . The identity of (II) with digitoxigenin is excluded by the differing physiological action of (I) and digitoxin (III), and the possibility of isomerisation due to differing position of OH at  $\text{C}_{10}$  is confirmed by the ability of thevetigenin (IV) to give an additive product with (III) from which *anhydrothevetigenin*,  $\text{C}_{23}\text{H}_{32}\text{O}_3$ , m.p.  $218\text{--}220^\circ$ ,  $[\alpha]_D^{20} +40.0^\circ$  in  $\text{CHCl}_3$ , is isolated; it is cautiously oxidised to anhydrodigitoxigenone. (IV) is therefore (A). Chen's kokilphin (*loc. cit.*) is identical with sucrose.

(A) appears the most probable structure of (I). H. W.

**Toad poisons. II. Cino- and marino-bufagin.** R. TSCHESCHE and H. A. OFFE (Ber., 1936, 69, [B], 2361—2367; cf. this vol., 81).—In agreement with Crowfoot (A., 1935, 921), but contrary to Kotake (A., 1928, 1138) and Jensen *et al.* (A., 1934, 412), fresh analyses of cinobufagin (I) agree with  $\text{C}_{26}\text{H}_{34}\text{O}_6$ . (I) therefore contains three double linkings, confirmed by quant. micro-hydrogenation. In the presence of a large amount of catalyst a slow further absorption of 4  $\text{H}_2$  is observed; this cannot be attributed to saturation of double linkings and is not shown by certain derivatives of (I) or by marino-bufagin (II). The ultra-violet absorption spectrum

of (I) and (II) agrees only with the presence of a conjugation of two C:C linkings with the C:O of the lactone group. The similarity of the absorption spectra of (I), (II), scillaren, and  $\text{CO} < \begin{array}{c} \text{CH}\cdot\text{CH} \\ \text{O}-\text{CH} \end{array} > \text{C}\cdot\text{CO}_2\text{Me}$ , the production of a free or latent  $\cdot\text{CHO}$  group when (I) is cautiously hydrolysed, and the formation of  $\text{HCO}_2\text{H}$  by ozonolysis of (I) indicate the presence of  $\cdot\text{C} < \begin{array}{c} \text{CH}\cdot\text{CH} \\ \text{CH}-\text{O} \end{array} > \text{CO}$  as found by Wieland *et al.* (this vol., 1252) in bufotalin and the subsidiary poisons. Hydrogenation of cinobufagin monoacetate, m.p.  $202^\circ$ , gives  $\alpha$ -, m.p.  $238^\circ$ , and  $\beta$ -, m.p.  $250^\circ$  (decomp.), *hexahydrocinobufagin monoacetate*, which differ probably only by the steric arrangement of a H and are identical with the two perhydrogenated cinobufagin acetates of Kotake (*loc. cit.*). These are cautiously hydrolysed to *α-deacetylhexahydrocinobufagic acid* (III),  $\text{C}_{24}\text{H}_{38}\text{O}_{15}\cdot 0.5\text{H}_2\text{O}$ , m.p. (indef.)  $160^\circ$ , which does not absorb H or give a colour with  $\text{C}(\text{NO}_2)_4$ , and the corresponding  $\beta$ -compound, m.p. (indef.)  $180^\circ$ ; the analytical data are complicated by the presence of  $\text{H}_2\text{O}$  of crystallisation which is very firmly retained, and the production of an  $\text{O}_5$  acid involves the elimination of  $\text{H}_2\text{O}$  with production of a double linking, the presence of which could not be detected. Cautious oxidation of (III) with  $\text{CrO}_3\text{-AcOH}$  at  $0^\circ$  gives *deacetylhexahydrocinobufagonic acid*,  $\text{C}_{24}\text{H}_{34}\text{O}_{15}$ , m.p.  $205^\circ$ . It is monobasic even in hot solution, and hence contains only the original  $\text{CO}_2\text{H}$ . It affords only a *monosemicarbazone*, decomp.  $217^\circ$ , and hence contains only 1 CO unless another is present at the non-reactive or sluggishly reactive  $\text{C}_{11}$  position

of the cholane skeleton. It has no appreciable absorption in the ultra-violet. (A) appears the most probable structure of (I). H. W.

**Mol. wt. of cinobufagin.** D. CROWFOOT and H. JENSEN (J. Amer. Chem. Soc., 1936, 58, 2018—2019; cf. A., 1935, 921).—X-Ray crystallographic data for cinobufagin (I), acetylcinobufagin, and cinobufagone indicate that (I) is  $\text{C}_{26}\text{H}_{34}\text{O}_6$ ; previous analytical data (A., 1934, 412) are in agreement.

H. B.

**Steric hindrance to the hydrogenation of the ethylenic linking in butadiene sulphones.** C. C. BOLT and H. J. BACKER (Rec. trav. chim., 1936, 55, 898—903).—3:4-Ditert.-butyl-2:5-dihydrothiophen 1:1-dioxide (I) resists hydrogenation by  $\text{H}_2\text{-PtO}_2$ , but with  $\text{H}_2\text{-Pd-black}$  in  $\text{AcOH}$  (1.4 atm.) gives 3:4-ditert.-butyltetrahydrothiophen 1:1-dioxide (II), b.p.  $171\text{--}171.5^\circ/14$  mm., m.p.  $76\text{--}76.5^\circ$ . 3:4-Diphenyl-2:5-dihydrothiophen 1:1-dioxide (III) resists hydrogenation at 1 atm., but at 1.4 atm. ( $\text{PtO}_2$ ) gives 3:4-dicyclohexyltetrahydrothiophen 1:1-dioxide (IV), b.p.  $210\text{--}212^\circ/12$  mm., m.p.  $143\text{--}143.5^\circ$ , whilst cessation of the reaction after absorption of 1 or 4  $\text{H}_2$  gives mixtures. However, 2:3-4:5-

*ditetramethylene-2:5-dihydrothiophen 1:1-dioxide* (V) (from di- $\Delta^1$ -cyclohexenyl and  $\text{SO}_2$ ), m.p. 77.5–78°, with  $\text{H}_2$ -Pt-black,  $-\text{PtO}_2$ , or  $-\text{Pd}$ -black at 1 atm. gives 2:3-4:5-*ditetramethylenetetrahydrothiophen 1:1-dioxide* (VI), m.p. 85.5–86°, b.p. 173–175°/6 mm. The  $\text{H}_2$ -compounds readily lose  $\text{SO}_2$  to regenerate the butadiene, decomp. temp. being (I) 116–118°, (III) 188–190°, and (V) 115°. The  $\text{H}_4$ -compounds decompose only at the b.p./760 mm., namely, (II) 270–275°, (IV) 350–360°, and (VI) 310°, but with  $\text{KMnO}_4$  or  $\text{CrO}_3$  at 50° give 1 mol. of  $\text{H}_2\text{SO}_4$ . R. S. C.

**Substitution derivatives of diphenylene sulphide and diphenylene sulphone.** N. M. CULLINANE, C. G. DAVIES, and G. I. DAVIES (J.C.S., 1936, 1435–1437).—Nitration ( $\text{HNO}_3$ -AcOH) of diphenylene sulphide (I) gives the 3- $\text{NO}_2$ -derivative, m.p. 186°, also obtained by reduction and deamination of 2:4-dinitrophenyl sulphide. The  $\text{NO}_2$ -compound on reduction, followed by  $\text{CuBr}$ , forms 3-bromo-diphenylene sulphide, m.p. 127°, obtained by bromination of (I). Nitration ( $\text{HNO}_3$ - $\text{H}_2\text{SO}_4$ ) of diphenylene sulphone (II) affords the 2:7-( $\text{NO}_2$ )-derivative, m.p. 290° (slight decomp.), reduced (Fe) to the 2:7-( $\text{NH}_2$ ) $_2$ -, which yields the 2:7- $\text{Br}_2$ -compound, m.p. 312°, also derived by bromination of (II). 3-Nitrodiphenylene sulphide is oxidised ( $\text{K}_2\text{Cr}_2\text{O}_7$ ) to the sulphone. F. R. S.

**Synthesis of heterocyclic compounds.** N. M. CULLINANE and (in part) C. G. DAVIES (Rec. trav. chim., 1936, 55, 881–886).—Dibenzfuran is obtained when 2:2'-dihydroxydiphenyl is boiled for 50 hr. (90% yield) or heated with  $\text{P}_2\text{O}_5$  at 300° for 26 hr. (95% yield).  $\text{KOPh}$  and  $o\text{-C}_6\text{H}_4\text{Cl}\cdot\text{OK}$  do not react at 120° or in boiling  $\text{PhOH}$ , but at 250° give a poor yield of diphenylene dioxide (9:10-dioxo-anthracene), obtained in 25% yield from  $o\text{-C}_6\text{H}_4\text{Cl}\cdot\text{ONa}$  at 250°. Benzidine sulphone (prep. in 93% yield from benzidine), m.p. 327°, by diazotisation and reaction with  $\text{EtOH}$  gives diphenylene sulphone (dibenzthiophen 1:1-dioxide), m.p. 235°, converted into dibenzthiophen, m.p. 99°, by S at 350°.  $\text{PhSH}$ ,  $o\text{-C}_6\text{H}_4\text{Cl}\cdot\text{NO}_2$ , and  $\text{KOH}$  at 190–195° give Ph  $o$ -nitrophenyl sulphide, m.p. 82° (cf. lit.; 85% yield), reduced by Fe- $\text{FeCl}_3$  (trace)- $\text{H}_2\text{O}$  to Ph 2-aminophenyl sulphide, m.p. 35°, the diazonium compound from which with Na xanthate or  $\text{K}_3\text{Cr}(\text{SCN})_6$  gives thianthren. R. S. C.

**Oxidation of thianthren and its oxides by peracetic acid.** J. BÖESEKEN and (MLLE.) A. T. H. VAN DER MEULEN (Rec. trav. chim., 1936, 55, 925–934).—*E* and *B* in the equation,  $\log K = B - E/2.303RT$ , for oxidation by  $\text{AcO}_2\text{H}$  are for thianthren (I) 16,750 and 8.9, its monosulphoxide 14,200 and 5.3, *trans*- 15,100 and 5.1, and *cis*-disulphoxide 13,600 and 3.5, respectively. The prep. of (I) (66.5% yield) is modified. The monosulphoxide could not be obtained by Fries and Vogt's method (A., 1911, i, 555) or modifications thereof. (I) has a dipole moment, but gives only two dioxides and one monosulphoxide; thus the two forms are labile. The rate of oxidation of S in (I) is decreased when the other S becomes SO. R. S. C.

**Indigoid dyes. IX. Absorption spectra of isomeric thioindigoid dyes.** P. C. DUTTA (Ber.,

1936, 69, [B], 2343–2346; cf. A., 1935, 1249).—Measurement of the absorption spectrum of 36 dyes of this series in  $\text{PhNO}_2$  confirms the conclusions reached previously (*loc. cit.*). H. W.

**Action of ammonia and amines on aryl chlorosulphates and the *N*-chlorosulphonylsulphonamides.** L. DENEVILLE (Bull. Soc. chim., 1936, [v], 3, 2143–2152).—Aryl chlorosulphates behave as chlorosulphonating agents towards  $\text{NH}_3$ , primary and *sec.* aliphatic and heterocyclic amines, giving *N*-chlorosulphonyl derivatives which, if sufficiently stable, give aminosulphonamides with excess of the amine. Under the same conditions, primary and *sec.* aromatic amines do not yield the corresponding amidosulphonamides; at a higher temp. they suffer oxidation. *tert.*-Aromatic amines give additive products at room temp. *N*-Chlorosulphonylsulphonamides resemble aryl chlorosulphates in their behaviour towards amines.  $\text{PhSO}_3\text{Cl}$ ,  $o\text{-C}_6\text{H}_4\text{Cl}\cdot\text{SO}_3\text{Cl}$ ,  $p\text{-NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{Cl}$ , and  $o$ - and  $p\text{-C}_6\text{H}_4\text{Me}\cdot\text{SO}_3\text{Cl}$  behave similarly except with regard to rate of reaction. Gradual addition of  $\text{PhSO}_3\text{Cl}$  to piperidine (I) in  $\text{C}_6\text{H}_6$  at room temp. affords  $\text{PhOH}$ , piperidine hydrochloride, and di-1:1'-piperidyl sulphone, m.p. 92°. (I) and  $\text{SO}_2\text{Cl}_2$  in  $\text{PhMe}$  at 0° give 1-chlorosulphonylpiperidine (II), b.p. 120°/14 mm., which is completely decomposed at about 150° and converted by a suspension of  $\text{NaOPh}$  in boiling  $\text{C}_6\text{H}_6$  into *Ph* sulphonpiperidamate,  $\text{C}_5\text{H}_{10}\text{N}\cdot\text{SO}_3\text{Ph}$ , m.p. 59–60°. (II) is also formed when (I) is added gradually to  $\text{PhSO}_3\text{Cl}$  in  $\text{PhMe}$  at 0°.  $\text{PhSO}_3\text{Cl}$  and  $\text{NH}_2\text{Et}_2$  (3 mols.) yield sulphitetetraethylamide,  $\text{SO}_2(\text{NEt}_2)_2$ , b.p. 101–102°/1 mm., or chlorosulphondiethylamide, b.p. 209°/atm. pressure, if the ester is in excess.  $\text{NH}_2\text{Me}$  gives  $\text{SO}_2(\text{NHMe})_2$ , m.p. 78°, and sulphdibenzylidiamide, m.p. 181–182°, is derived from  $\text{CH}_2\text{Ph}\cdot\text{NH}_2$ .  $\text{PhSO}_3\text{Cl}$  and  $\text{NH}_3$  react:  $\text{PhSO}_3\text{Cl} + \text{NH}_3 \rightarrow \text{PhOH} + \text{NH}_2\cdot\text{SO}_2\text{Cl}$  (III) and 3(III) ( $\text{SO}_2\cdot\text{NH}$ ) $_3$  +  $3\text{HCl}$ .  $\text{PhSO}_3\text{Cl}$  oxidises  $\text{NH}_2\text{Ph}$  and  $\text{NHPhMe}$  with evolution of  $\text{SO}_2$ ; with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  diaminophenazine is produced.  $\text{NPhMe}_2$  and  $\text{PhSO}_3\text{Cl}$  in cold  $\text{C}_6\text{H}_6$  yield the non-cryst. compound,  $\text{C}_6\text{H}_5\text{O}_3\text{SCl}\cdot\text{C}_8\text{H}_{11}\text{N}$ . H. W.

**4-Keto-3:5-dialkylpiperidines.** C. MANNICH and P. SCHUMANN (Ber., 1936, 69, [B], 2299–2305).—4-Keto-3:5-dialkylpiperidines are obtained by condensing  $\alpha\alpha'$ -dialkylacetonedicarboxylic esters with  $\text{NH}_2\text{Me}$  and  $\text{CH}_2\text{O}$  (which cannot be replaced by other aldehydes) at room temp. followed by hydrolysis of the esters so produced and decarboxylation of the acids. Thus  $\text{Et}_2$  diethylacetonedicarboxylate,  $\text{NH}_2\text{Me}$ , and 35%  $\text{CH}_2\text{O}$  in  $\text{EtOH-H}_2\text{O}$  afford  $\text{Et}_2$  4-keto-1-methyl-3:5(*cis*)-diethylpiperidine-3:5-dicarboxylate (I), b.p. 176°/13 mm. (*perchlorate*, m.p. 166°; *hydrochloride*, m.p. 147°; *picrate*, m.p. 143°; *methiodide*, decomp. 164–165°). (I) is converted by boiling 25%  $\text{HCl}$  into 4-keto-1-methyl-3:5(*cis*)-diethylpiperidine, b.p. 93°/11 mm. [*hydrobromide* (II), m.p. 168–169°; *hydrochloride*, m.p. 133–135°; *methiodide*, m.p. 254° (decomp.); *oxime*, m.p. 196°]. (II) is reduced by  $\text{Na-Hg}$  in dil.  $\text{AcOH}$  to 4-hydroxy-1-methyl-*cis*-3:5-diethylpiperidine,  $\alpha(\psi)$ -form (III), m.p. 99° (*hydrochloride*, m.p. 188–189° after softening; *perchlorate*, m.p. 154–156°; *methiodide*, m.p.

251—252.5°; benzoate and its methiodide, m.p. 220° after softening at 210°, and  $\beta$ -variety, b.p. 118—122°/13 mm. (methiodide, m.p. 250—251°; benzoate and its methiodide, m.p. about 260°). (III) is not isomerised by 10% NaOEt at 175°.  $Et_2$  4-keto-1-methyl-cis-3:5-diallylpiperidine-3:5-dicarboxylate, b.p. 183—184°/11 mm. (hydrochloride, m.p. 131°), is converted by HBr in AcOH at room temp. into  $Et_2$  4-keto-1-methyl-3:5-di- $\beta$ -bromopropylpiperidine-3:5-dicarboxylate (hydrobromide, m.p. 160° when slowly heated), and reduced (PtO<sub>2</sub> in EtOH) to  $Et_2$  4-keto-1-methyl-cis-3:5-dipropylpiperidine-3:5-dicarboxylate, b.p. 185—186°/12 mm. [hydrochloride (III), m.p. 138°]. (III) is hydrolysed and decarboxylated by boiling 25% HCl to 4-keto-1-methyl-cis-3:5-dipropylpiperidine (IV), b.p. 120°/11 mm. (*H* tartrate, m.p. 81—82°; oxime, m.p. 93—94°, and its hydrochloride, decomp. 225°), the methiodide, m.p. 165—166° after darkening when rapidly heated, of which is transformed by hot 15% KOH followed by MeI into the methiodide (V), CH<sub>3</sub>·CPr<sup>+</sup>·CO·CHPr<sup>+</sup>·CH<sub>2</sub>·NMe<sub>3</sub>I, m.p. 148° after softening at 145—147°. Treatment of (V) with KOH affords  $\alpha\alpha'$ -dipropyldivinyl ketone, b.p. 84—85°/12 mm., hydrogenated (PtO<sub>2</sub> in MeOH) to  $\alpha\alpha'$ -dimethyldibutyl ketone, b.p. 86°/13 mm. (IV) is reduced to 4-hydroxy-1-methyl-cis-3:5-dipropylpiperidine,  $\alpha(\psi)$ -form, m.p. 112—113° (perchlorate, m.p. 113—115°; nitrate, m.p. 137—138°; sulphate, m.p. 170—171°; non-cryst. benzoate and its hydrochloride, m.p. 109—111°, picrate, m.p. 190—193°, and methiodide, m.p. 270—272°), and  $\beta$ -variety, m.p. 63—65° (methiodide, m.p. 225—227°; benzoate and its picrate, m.p. 205—209°, and methiodide, m.p. about 295°). Na amlyoxide in boiling NH<sub>2</sub>Ph isomerises the  $\beta$ - to the  $\alpha$ -form, but is without action on the latter. H. W.

**Tricyclic oxetone derivatives.** C. MANNICH and P. SCHUMANN (Ber., 1936, 69, [B], 2306—2310).—Treatment of  $Et_2$  4-keto-1-methyl-3:5-diallylpiperidine-3:5-dicarboxylate hydrochloride with boiling 25% HCl gives 1:5':5''-trimethyl-3':2'-3:4-2'':3'-4:5-ditetrahydrofuranopiperidine (I), b.p. 113°/11 mm.

[hydrochloride, m.p. 220—221°; methiodide (II), m.p. 238°], which does not contain CO or active H (Zerevitinov) and does not add Br or H. The base obtained from (II) and Ag<sub>2</sub>O passes when heated into  $\beta\epsilon\epsilon\theta$ -dioxido-8-dimethylaminomethyl- $\zeta$ -methylenenonane,  $\begin{array}{c} \text{CH}_2-\text{CHMe}-\text{O} \\ \diagup \quad \diagdown \\ \text{CH}(\text{CH}_2\cdot\text{NMe}_2) < \text{C} < \text{O} \\ \diagdown \quad \diagup \\ \text{C}(\text{CH}_2)-\text{CH}_2 \end{array}$ , b.p. 115°/11 mm. (hygroscopic hydrochloride; picrate, m.p. 147°), the methiodide (II), m.p. 207—208°, of which is hydrogenated (PtO<sub>2</sub>) to  $\beta\epsilon\epsilon\theta$ -dioxido- $\zeta$ -methyl-8-dimethylaminomethylnonane methiodide (III), m.p. 195—197°. (III) is degraded to NMe<sub>3</sub> and  $\beta\epsilon\epsilon\theta$ -dioxido-8'-dimethylenenonane (IV), b.p. 86—87°/13 mm., whilst (III) yields  $\beta\epsilon\epsilon\theta$ -dioxido- $\zeta$ -methyl-8-methylenenonane (V), b.p. 84—88°/13 mm.; hydrogenation of (IV) or (V) (PtO<sub>2</sub> in MeOH) leads to  $\beta\epsilon\epsilon\theta$ -dioxido-8 $\zeta$ -dimethylnonane, b.p. 88—92°/13 mm. (I) is transformed by HBr·AcOH at 75° into the non-cryst., unstable 4-keto-1-methyl-cis-3:5-di- $\beta$ -bromopropylpiperidine [hydrobromide (VI), m.p. 164—165° (decomp.)], quantitatively reconverted into (I) by

H<sub>2</sub>O at 100°]. (VI) is reduced (PtO<sub>2</sub> in EtOH) to 4-hydroxy-1-methyl-cis-3:5-di- $\beta$ -bromopropylpiperidine, m.p. 125—126°. 2:6-Diallylcyclohexanone is converted by HBr·AcOH at room temp. into the unstable 2:6-di- $\beta$ -bromopropylcyclohexanone, m.p. 94—95°, transformed by boiling H<sub>2</sub>O containing KHCO<sub>3</sub> into 5':5''-dimethyl-3':2'-2'':3''-ditetrahydrofuranol-1:2-2:3-cyclohexane, b.p. 115—117°/14 mm.

H. W.

**2-Aminopyridine series.** IV. Reactivity of the methyl group in 6-amino-2-picoline. K. FEIST, W. AWE, and M. KUKLINSKI. V. Reactivity of the amino-group in 6-amino-2-picoline. K. FEIST and M. KUKLINSKI (Arch. Pharm., 1936, 274, 418—425, 425—435).—IV. Unlike that of 2-picoline the Me of 6-amino-2-methylpyridine (I) (benzyl, m.p. 66°, and formylbenzyl, m.p. 76°, derivatives) or its *N*-Me derivatives does not react with *o*- or *p*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO to give stilbazoles (cf. Shaw *et al.*, A., 1933, 282). 6-Dimethylamino-2-methylpyridine with Ac<sub>2</sub>O gives the Ac derivative, b.p. 264°, of 6-methylamino-2-methylpyridine, b.p. 209—210° (picrate, m.p. 192°); attempted condensation of this in Ac<sub>2</sub>O with *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO gives  $\beta$ -hydroxy- $\beta$ -2-nitrophenylpropionic acid, b.p. 175—185°/14 mm., m.p. 87°. Picrates of 2-stilbazole, m.p. 207°, and 2-dihydrostilbazole, m.p. 128°, were also prepared.

V. (I) forms Schiff's bases with many aromatic aldehydes, but with *o*-OH·C<sub>6</sub>H<sub>4</sub>·CHO and *o*-NO<sub>2</sub>·C<sub>6</sub>H<sub>4</sub>·CHO reacts slowly to give yellow products regarded as Me·C<sub>5</sub>H<sub>3</sub>N·NH·N:CH< $\begin{array}{c} \text{CH}\cdot\text{CH} \\ \diagup \quad \diagdown \\ \text{CO}\cdot\text{CH} \end{array}$ >CH. Such are 6-*o*-methoxy-, m.p. 84°, and 6-*o*-hydroxy-benzylideneamino-2-methylpyridine, m.p. 68°, hydrogenated (Pd-black) to 6-*o*-methoxy-, m.p. 69° [also from (I) and *o*-OMe·C<sub>6</sub>H<sub>4</sub>·CHO in anhyd. HCO<sub>2</sub>H], and 6-*o*-hydroxy-benzylamino-2-methylpyridine, m.p. 97°. The following were similarly prepared: 6-*o*-, m.p. 114.5°, and 6-*p*-nitro-, m.p. 161°, -nitro-3:4-dimethoxy-, m.p. 139°, and 6-3':4'-methylenedioxy-benzylideneamino-2-methylpyridine, m.p. 118°; 6-3':4'-methylenedioxybenzylamino-2-methylpyridine, m.p. 80°, also from (I) with piperonal in anhyd. HCO<sub>2</sub>H. (I) with S in CS<sub>2</sub> and EtOH yields NN-bis-(2-methylpyridine)-6-thiocarbamide, m.p. 209°, and 6-thiourethano-2-methylpyridine, m.p. 113°. (I) with CH<sub>2</sub>:CH·CH<sub>2</sub>·NCS yields 2-methylpyridine-6-allylthiocarbamide, m.p. 170°, which with 2*N*-NaOH, EtOH, and 10% Pb(OAc)<sub>2</sub> gives the corresponding carbamide, m.p. 139°. Similarly PhNCS gives phenyl-2-methylpyridine-6-thiocarbamide, m.p. 196°, and -carbamide, m.p. 186°. 2-Aminopyridine (II) and CO(NH<sub>2</sub>)<sub>2</sub> with butylchloral yield respectively 2-(di- $\beta\beta\gamma$ -trichloro- $\alpha$ -hydroxybutylamino)pyridine, m.p. 109°, and  $\beta\beta\gamma$ -trichloro- $\alpha$ -hydroxybutylcarbamide, m.p. 156°. C<sub>5</sub>H<sub>5</sub>N with  $\omega$ -chloro-3:4-dihydroxyacetophenone yields an additive compound with pyridine (hydrate, m.p. 269°; picrate, m.p. 190°). 2-( $\beta$ -Hydroxy- $\beta$ -3':4'-dihydroxyphenylethylamino)pyridine hydrochloride (A., 1934, 417) gives a picrate, m.p. 199°. F. R. G.

**Reduction products of nicotinamide methiodide.** II. P. KARRER and F. BENZ (Helv. Chim. Acta, 1936, 19, 1028—1029; cf. this vol., 1121).—The orange-coloured intermediate product formed during the reduction of nicotinamide methiodide by

$\text{Na}_2\text{S}_2\text{O}_4$  in aq.  $\text{NaHCO}_3$  or  $\text{Na}_2\text{CO}_3$  cannot be removed by  $\text{CHCl}_3$ . A similar effect is observed with many other quaternary pyridinium salts and appears characteristic of reduction to the *o*- $\text{H}_2$ -stage. The yellow colorations have nothing in common with those produced by the reduction of cozymase in strongly alkaline solution. 1-Methyldihydronicotinamide has been obtained cryst. H. W.

**Manufacture of heterocyclic compounds.** [Pyridines and pyrrolidines.]—See B., 1936, 1083.

**Manufacture of carboxylic acids or derivatives thereof containing the pyridine nucleus.**—See B., 1936, 1084.

**Interaction of tetraphenyl glycol and pyridinium chloride.** A. SCHONBERG and R. MICHAELIS (J.C.S., 1936, 1571).—Tetraphenyl glycol,  $\text{C}_6\text{H}_5\text{N}$ , and  $\text{HCl}$  give a substance, m.p. 185–190° (decomp.), probably  $\text{OH}\cdot\text{CPh}_2\cdot\text{CPh}_2\cdot\text{OH}\cdot\text{C}_5\text{H}_5\text{N}\cdot\text{HCl}$ , decomposed by alkali into its components. F. R. S.

**Nitrogenous substances analogous to terphenyl [2:5-diphenylpyridines].** M. COLONNA (Gazzetta, 1936, 66, 528–532).— $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ , *o*-, *m*-, or *p*- $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{CHO}$ , and  $\text{AcCO}_2\text{H}$  yield respectively 2-*o*- (cf. A., 1907, i, 853), 2-*m*-, m.p. 282° (decomp.), and 2-*p*-nitrophenyl-5:6- $\alpha\beta$ -naphthoquinoline-4-carboxylic acid, m.p. 262°, with *o*-, *m*-, or *p*-nitrobenzyl- $\beta$ -naphthylamine. The above acids are oxidised by  $\text{NaOH}\text{-KMnO}_4$  to 6-(2'-nitrophenyl)-3-(2''-carboxyphenyl)-, m.p. 287° (decomp.), 6-(3'-nitrophenyl)-3-(3''-carboxyphenyl)-, m.p. 115° (decomp.), and 6-(4'-nitrophenyl)-3-(4''-carboxyphenyl)-pyridine-2:4-dicarboxylic acid, m.p. 170°. E. W. W.

**Condensation of aromatic formamido-derivatives with pyruvic acid.** A. SILBERG (Bull. Soc. chim., 1936, [v], 3, 1767–1776).—This condensation does not follow the mechanism proposed by van Schelven (B., 1933, 341). Formanilides and  $\text{AcCO}_2\text{H}$  (I) in  $\text{EtOH}$  yield 2-methylquinoline-4-carboxylic acids (II), apparently by the stages  $\text{NHR}\cdot\text{CHO} \rightarrow \text{NH}_2\text{R} \rightarrow \text{NR}\cdot\text{CHMe} \rightarrow \text{NHR}\cdot\text{CHMe}\cdot\text{CH}\cdot\text{C}(\text{OH})\cdot\text{CO}_2\text{H} \rightarrow$  (II); secondary products are also formed. Thus  $\text{NHPh}\cdot\text{CHO}$  and (I) give (in  $\text{EtOH}$  at the b.p.) 2-methylquinoline-4-carboxylic acid [also obtained from  $\text{NH}_2\text{Ph}$  and (I)] and (especially in the cold)  $\beta$ -anilinoacrylanilide, m.p. 236°. Form-*p*-anisidide (III) in  $\text{EtOH}$  gives 6-methoxy-2-methylquinoline-4-carboxylic acid (*Cu* salt); with (I) alone at 120° (III) yields  $\gamma$ -*p*-anisidino- $\alpha$ -ketovaleric acid (?), m.p. 200°. *p*- $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OME}$  and (I) in  $\text{EtOH}$  yield pyrotartrodip-anisidide. Form-*o*- and -*p*-toluidide give 2:8-, m.p. 153°, and 2:6-dimethylquinoline-4-carboxylic acid, m.p. 263° (decomp.), respectively. Form- $\alpha$ - and - $\beta$ -naphthylamide condense to 2-methyl- $\alpha$ -naphthoquinoline-4-carboxylic acid, m.p. 245°, and 3-methyl- $\beta$ -naphthoquinoline-1-carboxylic acid, m.p. 290°. *m*-Bromoformanilide gives 7(or 8)-bromo-2-methylquinoline-4-carboxylic acid, m.p. 187° (decomp.). *p*-Bromoformanilide and (I) in  $\text{EtOH}$  at the b.p. furnish a neutral substance,  $\text{C}_{17}\text{H}_{15}\text{N}_2\text{Br}_3$ , m.p. 222°; in the cold a substance,  $\text{C}_9\text{H}_8\text{ONBr}$ , is obtained. *o*-Bromoformanilide gives a substance,  $\text{C}_{10}\text{H}_8\text{O}_2\text{N}_2\text{Br}$ , m.p. 204–205°. E. W. W.

**Manufacture of derivatives of anthraquinone series.** Manufacture of 3-hydroxy-2-methylquinoline-4-carboxylic acid and derivatives.—See B., 1936, 976.

**Addition of benzene to 2- and 4-styrylquinolines.** R. C. FUSON, L. L. ALEXANDER, E. ELLINGBOE, and A. HOFFMAN (J. Amer. Chem. Soc., 1936, 58, 1979–1980).—4-*p*-Chlorostyrylquinoline, m.p. 127–128° (from 4-methylquinoline,  $p\text{-C}_6\text{H}_4\text{Cl}\cdot\text{CHO}$ , and a little  $\text{ZnCl}_2$  at 125°), and 4-styrylquinoline (I) with  $\text{C}_6\text{H}_6$  (excess),  $\text{AlCl}_3$ , and  $\text{HCl}$  both give 4- $\beta\beta$ -diphenylethylquinoline, m.p. 130–131°.  $\text{MgPhBr}$  and (I) afford 2-phenyl-4-styrylquinoline, m.p. 102.5–103.5°. 2- $\beta\beta$ -Diphenylethylquinoline (A., 1933, 721) is also prepared by reduction of 2- $\beta\beta$ -diphenylvinylquinoline (II) with (i)  $\text{H}_2 + \text{PtO}_2$ , and (ii)  $\text{C}_6\text{H}_6$ ,  $\text{AlCl}_3$ , and  $\text{HCl}$ . 2- $\beta$ -Hydroxy- $\beta$ -phenyl- $\beta$ -*p*-chlorophenylethylquinoline, m.p. 140.5–141° (which could not be dehydrated), and (II) are obtained by Ziegler and Zeiser's method (A., 1931, 364). H. B.

**Synthesis of substituted 5:6-benzocinchonic acids by the Doebner and Pfitzinger reactions.** E. A. ROBINSON and M. T. BOGERT (J. Org. Chem., 1936, 1, 65–75).— $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ , various aldehydes, and  $\text{AcCO}_2\text{H}$  or  $\text{CH}_2\text{Bz}\cdot\text{CO}\cdot\text{CO}_2\text{H}$  give 3-substituted 5:6-benzocinchonic acids (A) and their Bz derivatives, respectively (with *N*-substituted naphthylamines formed by oxidation of the dihydrocinchonic acids at the expense of the anils which are primary products), which by decarboxylation or soda fusion, respectively, lead to 3-substituted benzoquinolines. (A) are also obtained by the Pfitzinger reaction from  $\beta$ -naphthisatin and acetophenones. Identity of the compounds obtained by the various methods is rigorously proved and structures are thereby confirmed. The following appear to be new. 3-*p*-Anisyl-5:6-benzoquinoline, m.p. 190–191° (lit. 184°) (picrate, m.p. 224°). 5:6-Benzocinchonic acid, m.p. 302° (uncorr.). 3-Methyl-5:6-benzoquinoline picrate, m.p. 228–230° (decomp.) (lit. 220–221°). 2-Benzoyl-5:6-benzocinchonic acid, decomp. 247° (chloride, m.p. 197–199°; *Et* ester, m.p. 146.5–147°), and its 3-*Me*, decomp. 271° (decomp.), -*Ph*, decomp. 249° [chloride, m.p. 205–206°; *Et* ester, m.p. 144° (sinters at 137–140°)], -*p*-anisyl, decomp. 237° (chloride, m.p. 181–183°; *Et*, m.p. 160–161°, and *Me* ester, m.p. 175–176°), and -piperonyl derivative, decomp. 259° (chloride, m.p. 188–189°; *Et* ester, m.p. 158–159°). *N*-*p*-Anisyl, m.p. 104.5° (lit. 98°) (hydrochloride, m.p. 195°), and -piperonyl- $\beta$ -naphthylamine, m.p. 119° (hydrochloride, m.p. 192°). 2-Benzoyl-3-methyl-, m.p. 132–133° (oxime, m.p. 242°; picrate, m.p. 216–217°), -phenyl-, m.p. 189° (lit. 185°) (picrate, m.p. 243–244°), -*p*-anisyl-, m.p. 186° (picrate, m.p. 199.5–200°), and -piperonyl-5:6-benzoquinoline, m.p. 210.5–211° [oxime, m.p. 262° (decomp.)]. M.p. are corr.

R. S. C.

**Acridones.** VIII. 10-Keto- and 10-keto-5-hydroxy-acridine. I. TANASESCU and E. RAMON-TIANU (Bull. Soc. chim., 1936, [v], 3, 2009–2018; cf. A., 1934, 1010).—In consequence of the somewhat divergent views of Lehmsedt (A., 1935, 1251) and Kliegl *et al.* (this vol., 343) proof is adduced that “10-hydroxyacridone” is 5-hydroxyacridine 10-oxide.

5-Chloroacridine is oxidised by  $\text{BzO}_2\text{H}$  in  $\text{CHCl}_3$  to *5-chloroacridine 10-oxide* (II), m.p.  $209^\circ$  (additive complex with  $\text{HgCl}_2$ ), hydrolysed by aq. alkali to 5-hydroxyacridine 10-oxide identical with that derived from  $o\text{-NO}_2\text{-C}_6\text{H}_4\text{-CHO}$ ,  $\text{C}_6\text{H}_6$ , and conc.  $\text{H}_2\text{SO}_4$ . It is also obtained from (I) and  $\text{NaOMe}$ . This synthesis is decisive and also establishes that "acridol" is intermediately produced by the action of alkali on 5-chloroacridine and then becomes isomerised to acridone. In the present case the isomerisation is impossible owing to the presence of O attached to N.

excluded since the absorption spectra in EtOH are closely similar in absence or presence of alkali. Reduction of the "5-methoxyacridine" of Lehmstedt (*loc. cit.*) with Zn dust in boiling EtOH containing  $\text{CaCl}_2$  give a basic substance ( $\text{C}_{15}\text{H}_9\text{N}$ )<sub>n</sub>, m.p.  $388^\circ$ , of undetermined constitution with some acridone; its physico-chemical behaviour indicates the annexed structure rather than

5-benzoyloxyacridine 10-oxide with conc.  $\text{HCl}$  in  $\text{EtOH-H}_2\text{O}$  gives 3-chloroacridone, identified by conversion into 3-chloro-5-*p*-dimethylaminophenylacridine, m.p.  $230^\circ$ . Similar hydrolysis of 3-chloro-5-benzoyloxyacridine 10-oxide gives a substance,  $\text{C}_{13}\text{H}_7\text{ONCl}_2$ , m.p.  $<360^\circ$ . H. W.

**Acridine. XV. Relationship between basicity and radical formation during the action of alkali metal on bases of the acridine series.** K. LEHMSTEDT, W. BRUNS, and H. KLEE (Ber., 1936, 69, [B], 2399—2405; cf. this vol., 999).—K-Na reacts initially with acridine (I) with production of

by union of two radicals. Interaction of various acridine bases with Na-K in  $\text{Et}_2\text{O}$  and decomp. of the products with EtOH invariably yields mixtures of *ms*-dihydroacridines with *ms*-tetrahydrodiacridyls, the proportion of the latter being the greater as the base is weaker. 4'-Methoxydiphenylamine-2'-carboxylic acid is converted by  $\text{PCl}_5$  in  $\text{C}_6\text{H}_6$  into 3-methoxyacridone (I), m.p.  $278^\circ$ , transformed into 3-methoxyacridine (II), m.p.  $104^\circ$  [hydrochloride (+2H<sub>2</sub>O)]. *mer*-Quinonoid salts,  $\text{C}_{14}\text{H}_{11}\text{O}_2\text{N}, \text{C}_{14}\text{H}_{11}\text{ON}, \text{HCl}, 2\text{H}_2\text{O}$  and  $\text{C}_{14}\text{H}_{11}\text{ON}, \text{C}_{15}\text{H}_{13}\text{O}_2\text{N}, \text{HCl}$ , are derived from (I) and (II) and from (II) and 3-methoxy-10-methylacridone, respectively. 2-Methyldiphenylamine-2'-carboxylic acid (improved prep. from  $o\text{-C}_6\text{H}_4\text{Cl-CO}_2\text{H}$ ,  $\text{K}_2\text{CO}_3$ ,  $o\text{-C}_6\text{H}_4\text{Me-NH}_2$ , and Cu powder) is almost quantitatively converted by  $\text{PCl}_5$  in  $\text{C}_6\text{H}_6$  followed by distillation with steam into 4-methylacridone, reduced by Na-Hg, and then dehydrogenated by  $\text{PhNO}_2$  to 4-methylacridine, m.p.  $88^\circ$  (hydrochloride, +2H<sub>2</sub>O).

3:7-Dimethylacridine hydrochloride (+2H<sub>2</sub>O) is described. The following are obtained from the products of the action of Na-K on the bases: *ms*-tetrahydro-5:5-di-3-methoxyacridyl, m.p.  $204^\circ$  in bath at  $185^\circ$ ; -5:5'-di-3:7-dimethylacridyl, m.p.  $228\text{--}229^\circ$  in bath at  $210^\circ$ ; -5:5'-di-4-methylacridyl, m.p.  $193^\circ$  in bath at  $175^\circ$ ; -5:5'-di-3:4-benzoylacridyl, m.p.  $165\text{--}168^\circ$  in bath at  $150^\circ$ . *ms*-Dihydro-3:4-benzoylacridine has m.p.  $158^\circ$ . H. W.

**Preparation and therapeutic properties of certain acridine derivatives.** I. Anil and styryl derivatives of 2:8-diaminoacridine and acridine-5-aldehyde respectively. W. L. GLEN, M. M. J. SUTHERLAND, and F. J. WILSON (J.C.S., 1484—1487).—The following anils have been prepared but are too insol. in  $\text{H}_2\text{O}$  for biological tests: 2:8-bis-benzylidene-, m.p.  $220^\circ$ , -cinnamylidene-, m.p.  $252^\circ$ , -*p*-dimethylaminobenzylidene-, m.p.  $230^\circ$ , -anisylidene-, m.p.  $241\text{--}242^\circ$ , and -salicylidene-aminoacridine, m.p.  $282^\circ$ . The styryl compounds have been obtained by condensing acridine-5-aldehyde with  $\alpha$ -picoline or quinaldine alkiodide with  $\text{C}_5\text{H}_{11}\text{N}$  as catalyst, and some therapeutic properties examined and recorded: 5-(2-pyridyl methiodide)-5-acridylethene, decomp.  $220\text{--}225^\circ$  (hydrochloride); s-2-pyridyl-5-acridylethene dimethiodide; s-(2-pyridyl ethiodide)-5-acridylethene and -(5-acridyl methiodide)ethene; s-(2-quinolyl methiodide)-5-acridylethene, m.p.  $220\text{--}225^\circ$  (decomp.) (hydrochloride); s-2-quinolyl-5-acridylethene dimethosulphate, dimethochloride, and dimethiodide; and s-(2-quinolyl ethiodide)-(5-acridyl methiodide)-ethene. F. R. S.

**Attempts to find new antimalarials. XV. Synthesis of acridine compounds related to atebirin.** R. R. GOODALL and W. O. KERMAK (J.C.S., 1936, 1546—1550).—*o*-Phenoxy-3-methoxyacridine, m.p.  $146\text{--}147^\circ$ , obtained from  $\text{PhOH}$  and the 5-Cl-compound, condenses with the appropriate amine to give: 5-( $\beta$ -diethylaminoethyl-methylamino)-(dihydrobromide, m.p.  $239\text{--}240^\circ$ ), -*n*-propylamino)-(dihydrobromide, m.p.  $142\text{--}143^\circ$ ), and -amino-3-methoxyacridine (dihydrobromide), and 5-( $\gamma$ -diethylamino-*n*-propylamino)-3-methoxyacridine dihydrobromide, m.p.  $242\text{--}245^\circ$ . 1:3:5-Trichloroacridine, m.p.  $175^\circ$ , obtained from 2:4-dichlorodiphenylamine-2'-carboxylic acid and  $\text{POCl}_3$ , with  $\text{PhOH}$  gives 1:3-dichloro-5-phenoxyacridine, m.p.  $171^\circ$ , which condenses with amines to form 1:3-dichloro-5-( $\beta$ -diethylaminoethylamino)-, m.p.  $121\text{--}122^\circ$ , and -( $\gamma$ -diethylamino-*n*-propylamino)-acridine (dihydrobromide, decomp.  $200^\circ$ ). 5-Chloro-1-bromo-, m.p.  $159\text{--}161^\circ$ , is converted into 1-bromo-5-phenoxy-3-methylacridine, m.p.  $145^\circ$ , which affords 1-bromo-5-( $\beta$ -diethylaminoethylamino)-, m.p.  $114^\circ$ , and -( $\gamma$ -diethylamino-*n*-propylamino)-3-methylacridine (dihydrobromide, decomp. about  $230^\circ$ ). 1:3:7-Trichloro-5-( $\gamma$ -diethylamino-*n*-propylamino)-, m.p.  $155^\circ$ , and 7-chloro-1-bromo-5-( $\gamma$ -diethylamino-*n*-propylamino)-3-methylacridine, m.p.  $130\text{--}131^\circ$ , and 1:4-dichloro-5-( $\gamma$ -diethylamino-*n*-propylamino)acridine dihydrobromide, decomp. about  $225\text{--}230^\circ$ , are also described.

F. R. S.

**Manufacture of acridinium compounds.**—See B., 1936, 1018.

**Constitution of Knoevenagel's "acetone-anil."** K. VON AUWERS (Ber., 1936, 69, [B], 2351—2352).—The structure assigned to the compound by Kalnin (this vol., 1123) is not in agreement with spectrochemical behaviour, which harmonises with that adopted by Reddelien (A., 1932, 1142). H. W.

**Manufacture of cyclohexenylalkylhydantoins.**—See B., 1936, 1018.

**Action of phenylcarbimide on insulin.**—See this vol., 1564.

**Sensitisation of photographic silver halide emulsions. Preparation of pyrazolone and other derivatives.**—See B., 1936, 1020.

**Oxidation of 1-phenyl-3-methyl-5-pyrazolone.** II. G. PERRONCITO (Gazzetta, 1936, 66, 563—565).—The product, m.p. 180°, of oxidising 1-phenyl-3-methyl-5-pyrazolone with dry  $\text{H}_3\text{AsO}_4$  (this vol., 614) is methenylbis-4-(1-phenyl-3-methyl-5-pyrazolone).  $\text{NHPh}\cdot\text{NHAc}$  is also formed, supporting the view that  $\text{NHAc}\cdot\text{NPh}\cdot\text{CO}\cdot\text{CHO}$  is an intermediate product. E. W. W.

**N-Arylbarbituric acids.** II. J. S. BUCK (J. Amer. Chem. Soc., 1936, 58, 2059—2061).—The following are prepared from  $\text{NH}\cdot\text{CO}\cdot\text{NHAr}$  and  $\text{CETr}(\text{CO}_2\text{Et})_2$  (method: this vol., 1125): 1-phenyl-, m.p. 149°, 1-o-, m.p. 134°, -m-, m.p. 138.5°, and -p-, m.p. 149.5°, -tolyl-, 1-o-, m.p. 176—177°, -m-, m.p. 139.5°, and -p-, m.p. 149°, -anisyl-, 1-o-, m.p. 142—143°, -m-, m.p. 125.5°, and -p-, m.p. 145°, -phenetyl-, and 1- $\alpha$ -, m.p. 158°, and - $\beta$ -, m.p. 161—162°, -naphthyl-5-ethyl-5-isobutylbarbituric acids; 1-phenyl-, m.p. 129°, 1-o-, m.p. 119°, -m-, m.p. 113—114°, and -p-, m.p. 115°, -tolyl-, 1-o-, m.p. 134°, -m-, m.p. 115—116°, and -p-, m.p. 120°, -anisyl-, 1-o-, m.p. 162—163°, -m-, m.p. 72—74°, and -p-, m.p. 100—101°, -phenetyl-, and 1- $\alpha$ -, m.p. 193—194°, and - $\beta$ -, m.p. 138°, -naphthyl-5-ethyl-5-isoamylbarbituric acids; 1-p-dimethylaminophenyl- $\alpha$ :5-diethyl-, m.p. 182°, -5-ethyl-5-n-, m.p. 157°, and -iso-, m.p. 153°, -butyl-, - $\alpha$ -ethyl-5-isoamyl-, m.p. 130°, and 1-p-diethylaminophenyl- $\alpha$ :5-diethyl-, m.p. 175°, -5-ethyl-5-n-, m.p. 125.5°, and -iso-, m.p. 140—141°, -butyl-, and -5-ethyl-5-isoamyl-, m.p. 125°, -barbituric acids. p-Dimethyl-, m.p. 183°, and p-diethyl-, m.p. 136.5°, -aminophenylcarbamides are described. All m.p. are corr. H. B.

**Isomerisation of acylated pyrazolines.** K. VON AUWERS and H. LUDWIG (Ber., 1936, 69, [B], 2347—2351).—Repeated attempts to re-obtain 5-methylpyrazoline-1-carboxylamide, m.p. 167—168°, from 5-methylpyrazoline (I) and  $\text{HCNO}$  (von Auwers, A., 1927, 1203) give only an isomeride, m.p. 119°, whereas ring-closure from  $\text{CH}_2\text{Cl}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{N}\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}_2$  (Maire, A., 1908, i, 290) and condensation of 3-methylpyrazoline (II) with  $\text{HCNO}$  give exclusively the product of m.p. 167—168°. Acyl migration occurred therefore during the original experiment but its cause has not been traced. The incidence of accidental influences in similar changes is illustrated by the behaviour of (I) towards boiling  $\text{ClCO}_2\text{Me}$ ; in one experiment the main product was *Me* 3-methylpyrazoline-1-carboxylate, b.p. 135°/14 mm. [decarboxylated to (II) and identified as the picrate, m.p. 149°], whereas in other experiments

*Me* 5-methylpyrazoline-1-carboxylate, b.p. 124—132°/14 mm., was mainly produced. Benzoylation of (II) proceeds normally and yields 1-benzoyl-3-methylpyrazoline, m.p. 98.5—99°, differing from the 5-Me isomeride, m.p. 156°. The possibility of isomerisation during the nitrosation of (I) could not be investigated owing to the instability of the product. The occurrence of isomerisation with alkylpyrazolines proves that the phenomenon is not caused by a tendency towards the production of conjugated systems and indicates that it is due to a striving towards a uniform distribution of masses in the mol. H. W.

**Derivatives of piperazine.** IX. Addition to conjugate systems. I. V. E. STEWART and C. B. POLLARD (J. Amer. Chem. Soc., 1936, 58, 1980—1981).—Piperazine (1 mol.) and  $\text{COAr}\cdot\text{CH}\cdot\text{CHAr}$  (2 mols.) in boiling PhMe give almost quant. yields of 1:4-di-( $\beta$ -aroyl- $\alpha$ -arylethyl)piperazines, which are decomposed by dil.  $\text{HCl}$  (not  $\text{H}_2\text{O}$ ) or  $\text{HCl}$  in  $\text{CHCl}_3$  or PhMe to the original components. The following are described: 1:4-di-( $\beta$ -benzoyl- $\alpha$ -phenylethyl)-, m.p. 128—128.3° (all m.p. are corr.); 1:4-di-( $\beta$ -p-chlorobenzoyl- $\alpha$ -p-chlorophenylethyl)-, m.p. 148.4—158.7°; 1:4-di-( $\beta$ -p-toluoyl- $\alpha$ -p-tolylolethyl)-, m.p. 175.4—175.8°; 1:4-di-( $\beta$ -benzoyl- $\alpha$ -m-nitro-, m.p. 143—144°, -o-chloro-, m.p. 110.9—111.3°, -p-chloro-, m.p. 146.8—147°, -p-methyl-, m.p. 145.5—146°, and -p-methoxy-, m.p. 109.5—110.1°, -phenylethyl)-; 1:4-di-( $\beta$ -p-chloro-, m.p. 117.7—118.1°, -p-bromo-, m.p. 116.3—117.3°, and -p-methyl-, m.p. 132—132.5°, -benzoyl- $\alpha$ -phenylethyl)-, and 1:4-di-( $\beta$ -p-toluoyl- $\alpha$ -n-anisylethyl)-, m.p. 149.8—150.2°, -piperazines. H. B.

**Manufacture of derivative of pyrazinemono-carboxylic acid.**—See B., 1936, 1130.

**Pyrrolidine derivatives.** III. Catalytic hydrogenation under pressure of pyridylpyrrole derivatives. E. OCHIAI, K. TSUDA, and S. IKUMA (Ber., 1936, 69, [B], 2238—2242).—With pyridylpyrrole derivatives catalytic hydrogenation ( $\text{PtO}_2$ ) under pressure first affects the  $\text{C}_5\text{H}_5\text{N}$  nucleus. The influence of substituents in the pyrrole nucleus is pronounced. Whereas Me has little effect,  $\text{CO}_2\text{Alk}$  markedly inhibits reaction as does Ac until it has been reduced to  $\cdot\text{CHMe}\cdot\text{OH}$  or Et. The following transpositions are described: 4-2'-pyridyl-2-methylpyrrole to 4-2'-piperidyl-2-methylpyrrole, m.p. 113—114° [hydrochloride, m.p. 228° (decomp.)]; p-nitrobenzoyl derivative, m.p. 140—141°, and 4-2'-piperidyl-2-methylpyrrolidine, b.p. 110°(bath)/6 mm. (di-3:5-dinitrobenzoyl derivative, m.p. 180°); 4-3'-pyridyl-2-methylpyrrole to 4-3'-piperidyl-2-methylpyrrolidine, b.p. 120—130°(bath)/6 mm. (aurichloride, decomp. 230°; di-3:5-dinitrobenzoyl derivative, m.p. 237°); 3-acetyl-4-2'-pyridyl-2-methylpyrrole to a base, b.p. 200°(bath)/0.03 mm., converted by  $\text{HI}$  (d 1.7) and red P at 130° into 4-2'-piperidyl-2-methyl-3-ethylpyrrole (hydrochloride, m.p. 214°) or into a base, b.p. 150—170°(bath)/0.03 mm., and thence into 4-2'-piperidyl-2-methyl-3-ethylpyrrolidine (di-p-nitrobenzoyl derivative, m.p. 239—240°); 3-acetyl-4-3'-pyridyl-2-methylpyrrole to 3-acetyl-4-3'-piperidyl-2-methylpyrrole, m.p. 184° (p-nitrobenzoyl, m.p. 198°, and Ac, m.p. 216°, derivatives); Et 4-3'-pyridyl-2-methylpyrrole-3-carboxylate to Et 4-3'-piperidyl-2-methylpyrrole-3-carboxylate, m.p. 137°

(Bz derivative, m.p. 174°); Et<sub>2</sub> 4-2'-pyridyl-2-methylpyrrole-3 : 5-dicarboxylate is hydrolysed to 3-carbethoxy-4-2'-pyridyl-2-methylpyrrole-5-carboxylic acid, decomp. 218°, decarboxylated at 220°/3 mm. to Et 4-2'-pyridyl-2-methylpyrrole-3-carboxylate, m.p. 120° (perchlorate, m.p. 205°; methiodide, m.p. 207°; ethiodide, m.p. 179°), which is hydrogenated to Et 4-2'-piperidyl-2-methylpyrrole-3-carboxylate (p-nitrobenzoyl, m.p. 210°, and Ac, m.p. 142°, derivatives).

H. W.

**Pyrimidines. CLIV. Pyrimidine side-chain reactions useful for synthesis of 1 : 3-diazines related structurally to vitamin-B<sub>1</sub>. CLV. Synthesis of thymine and its conversion into uracil.** A. LITZINGER and T. B. JOHNSON (J. Amer. Chem. Soc., 1936, 58, 1936—1939, 1940—1942).—CLIV (cf. A., 1935, 991). 6-Hydroxy-2-ethylthiolpyrimidine-5-acetylhydrazide, m.p. 207—208° (decomp.) (from the Et ester and EtOH-N<sub>2</sub>H<sub>4</sub>.H<sub>2</sub>O), is converted into the azide (I), m.p. 175—180° (decomp., after evolution of N<sub>2</sub> at 75—80°), and thence (in PhMe) into 6-hydroxy-2-ethylthiol-5-carbimidomethylpyrimidine (II), m.p. 189—191° (decomp.). (II) with warm H<sub>2</sub>O gives mainly s-di-(6-hydroxy-2-ethylthiolpyrimidine-5-methyl)carbamide, m.p. 270—272° (decomp.), and a little 6-hydroxy-2-ethylthiol-5-aminomethylpyrimidine, m.p. 221—222° (decomp.) [N-CO<sub>2</sub>Et- (III), m.p. 148.5—149.5°, and N-CO<sub>2</sub>CH<sub>2</sub>Ph- (IV), m.p. 159—160°, derivatives, obtained from (I) or (II) with EtOH and CH<sub>2</sub>Ph.OH, respectively]. (II) with aq. NH<sub>3</sub> and NH<sub>2</sub>Ph (in dioxan) affords 6-hydroxy-2-ethylthiol-5-carbamido-, m.p. 190—192° (decomp.), and -5-phenylcarbamido-, m.p. 223—224° (decomp.), -methylpyrimidine, respectively. Uracil-5-acetylhydrazide, decomp. about 326° (darkens at 285°), is similarly converted through the azide, m.p. 275—276° (decomp., after evolution of N<sub>2</sub> at 75—80°), into thyminecarbamide [5-carbimidomethyluracil] (V),  $\text{CO} \begin{smallmatrix} \text{NH} \cdot \text{CO} \\ \text{NH} \cdot \text{CH} \end{smallmatrix} > \text{C} \cdot \text{CH}_2 \cdot \text{NCO}$ , m.p. 273—275° (decomp.), and thence (boiling H<sub>2</sub>O) into s-dithyminecarbamide, decomp. 315°. Et (VI), m.p. 256—257°, and benzyl, m.p. 261—263° (decomp.), thyminecarbamates are obtained by hydrolysis (warm EtOH—conc. HCl) of (III) and (IV), respectively.

CLV. Partly a more detailed account of work previously reviewed (this vol., 1126). Thyminecarbamide [5-aminomethyluracil] (VII), m.p. 260—270° (decomp.) [hydrochloride (+0.5 H<sub>2</sub>O), m.p. 242—243° (decomp.); sulphate (+H<sub>2</sub>O) (VIII), m.p. 245—246° (decomp.)], is obtained (not absolutely pure) by hydrolysis (HCl or H<sub>2</sub>SO<sub>4</sub>) of the above (II), (III), (V), and (VI). (VII) is further hydrolysed (conc. HCl and to some extent by boiling H<sub>2</sub>O) to uracil (IX), CH<sub>2</sub>O, and NH<sub>3</sub>. (VII) with Ba(NO<sub>3</sub>)<sub>2</sub> and 0.2M-H<sub>2</sub>SO<sub>4</sub> gives impure thymine alcohol [5-hydroxymethyluracil], m.p. 190—200° [also hydrolysed to (IX)], which could not be synthesised from (IX) and CH<sub>2</sub>O. (VII) and N oxides in H<sub>2</sub>O give the compound,

NH·CH·C·CH, m.p. 195—200°. Thyminecarbamide, m.p. 204—205°, is prepared from (VIII) and NH<sub>4</sub>NCS.

H. B.

**Synthesis of benziminazole derivatives.** R. WEIDENHAGEN (Ber., 1936, 69, [B], 2263—2272).—

The author's glyoxaline synthesis (A., 1935, 1380, 1507) is extended to benziminazoles. o-C<sub>6</sub>H<sub>4</sub>(NH<sub>2</sub>)<sub>2</sub>, Cu(OAc)<sub>2</sub>, and MeCHO in H<sub>2</sub>O afford the Cu derivatives of 2-methylbenziminazole, whence the parent compound, m.p. 175—176°, in 75% yield. The following -benziminazoles and the corresponding Cu<sup>I</sup> derivatives are analogously obtained: 2-ethyl-, m.p. 174—175°; 2-n-propyl-, m.p. 157—159°; 2-isopropyl-, m.p. 228°; 2-n-butyl-, m.p. 149—151°; 2-isobutyl-, m.p. 186—187°; 2-n-amyl-, m.p. 159—161°; 2-n-hexyl-, m.p. 136—138°; 2-β-dimethyl-Δ<sup>αα</sup>-heptadienyl- (from citral), m.p. (indef.) 102°; 2-phenyl-, m.p. 290°; 2-o-nitrophenyl- hydrochloride, m.p. 291° (decomp.); 2-m-nitrophenyl- (+1H<sub>2</sub>O), m.p. 204°; 2-p-nitrophenyl- hydrochloride, m.p. 310° (decomp.); 2-4'-hydroxy-3'-methoxyphenyl-, m.p. 221—222°; 2-p-methoxyphenyl-, m.p. 228—230°; 2-3' : 4'-methylene-dioxyphenyl-, m.p. 249°; 2-styryl-, m.p. 201—202°; 2-furyl-, m.p. 285—286°. Et 2-ethylbenziminazole-5-carboxylate, m.p. 151°, and Et 2-hexylbenziminazole-5-carboxylate hydrochloride, m.p. 238—240°, are derived from (NH<sub>2</sub>)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>·CO<sub>2</sub>Et. 2-iso-Propyl-, m.p. 239—240°, and 2-n-hexyl-, m.p. 199—202°, -1' : 2'-naphthiminazole are described.

H. W.

**Complex benzylation products of indigotin.** Höchst Yellow U. E. HOPE and J. S. ANDERSON (J.C.S., 1936, 1474—1478).—Methylation (Me<sub>2</sub>SO<sub>4</sub>—NaOH) of the “monohydrate of Höchst Yellow U” (cf. Posner *et al.*, A., 1929, 1313) gives a Me<sub>2</sub>, m.p. 167—168°, and a Me derivative, m.p. 238—240° (decomp.). Höchst Yellow U (I) and 15% NaOH at 215° afford an NH<sub>2</sub>-acid, m.p. 232° (efferv.) [(+2H<sub>2</sub>O), m.p. 182° (efferv.); NH<sub>4</sub> salt; Bz derivative, m.p. 212—213°, and (+H<sub>2</sub>O), m.p. 265—267° (efferv.); Ac derivative, m.p. 272°; Me<sub>2</sub> derivative, m.p. 238—239°, converted by HCl into an acid (+2H<sub>2</sub>O), m.p. 308—310° (decomp.)], which when heated forms a product, m.p. 230—231°; at the same time, an acid (+H<sub>2</sub>O), m.p. 206—208° (methylation product, m.p. 247—249°), is also obtained. These results are not in agreement with the formula of de Diesbach *et al.* (A., 1934, 306) for (I) and the alternative

F. R. S.

**Manufacture of heterocyclic hydroxy-compounds.**—See B., 1936, 977.

**C-Aminophthalazone and N-aminophthalimidine.** A. DARAPSKY and P. HEINRICHS (J. pr. Chem., 1936, [ii], 146, 307—318).—Phthalazonecarboxylic acid (I), m.p. 232° (NH<sub>4</sub>, m.p. 237°, and N.H<sub>4</sub>, m.p. 249—250°, salts), obtained by the direct action of N<sub>2</sub>H<sub>4</sub>.H<sub>2</sub>SO<sub>4</sub> on the product of the oxidation of C<sub>10</sub>H<sub>8</sub>, is esterified by HCl-MeOH and HCl-EtOH to the Me, m.p. 211°, and Et, m.p. 169°, ester. The latter is transformed by N<sub>2</sub>H<sub>4</sub>.H<sub>2</sub>O in boiling abs. EtOH into phthalazonecarbohydrazide, m.p. 234° (hydrochloride; :CHPh, m.p. >390°, o-hydroxybenzylidene-, m.p. >290°, and anisylidene-, m.p. >290°, derivatives), whence phthalazonecarboazide, transformed by warm NH<sub>2</sub>Ph into the corresponding anilide, m.p. 288°, and by boiling EtOH into Et phthalazonecarbamate, m.p. 207°, whence 4-amino-phthalazone (II), m.p. 257—258° (hydrochloride, m.p.

240°; *perchlorate*, m.p. 209°). (II) is transformed by  $\text{NaNO}_2$  into phthalhydrazide. Reduction of (I) with Zn dust and conc.  $\text{HCl}$  at 100° yields *phthalimidine-carboxylic acid*,  $\text{CO} \begin{array}{c} \text{NH} \\ \text{C}_6\text{H}_4 \end{array} \text{CH} \cdot \text{CO}_2\text{H}$ , m.p. 146—147°, which loses  $\text{CO}_2$  when heated above its m.p. and yields phthalimidine. With Zn dust in alkaline solution reduction occurs without loss of N, and gives rise to *aminophthalimidinecarboxylic acid*,

$\text{CO} \begin{array}{c} \text{N}(\text{NH}_2) \\ \text{C}_6\text{H}_4 \end{array} \text{CH} \cdot \text{CO}_2\text{H}$ , m.p. 140° [*hydrochloride*, m.p. 188°;  $\cdot\text{CHPh}$ , m.p. 106°, *o*-hydroxybenzylidene, m.p. 276°, and  $\text{Bz}$ , m.p. 141—142° (decomp.), derivatives]. Similarly phthalazone is reduced to *aminophthalimidine* ( $\cdot\text{CHPh}$ , m.p. 206°, and *o*-hydroxybenzylidene, m.p. 276°, derivatives). Attempts to reduce (I) (Pd or Pt in alkaline or  $\text{AcOH}$  solution) without altering the structure of the six-membered pyridazine ring were unsuccessful. H. W.

### Hydroxypolyketones. III. Benzoylformoin.

A. H. BLATT (J. Amer. Chem. Soc., 1936, 58, 1894—1899).—Benzoylformoin (I) and its open-chain  $\text{Alk}_1$  derivatives (cf. A., 1935, 982) react either as ene-diols or hydroxyketodihydrofurans; the cyclic  $\text{Alk}_1$  and  $\text{Alk}_2$  derivatives are ketoalkoxydihydrofurans. Distillation of (I) at about 240°/0.5 mm. gives an unstable red liquid, probably  $\begin{array}{c} \text{OH} \cdots \cdots \text{O} \\ \text{CPh} \cdot \text{C}(\text{OH}) \cdot \text{CBz} \end{array}$  (dotted line indicates chelation), which gradually reverts to the stable, yellow cryst. form (2:4-dihydroxy-3-keto-2:5-diphenyl-2:3-dihydrofuran). (I) and  $\text{Cu}(\text{OAc})_2$  in  $\text{Et}_2\text{O}$  afford a brown *Cu* derivative,  $\text{C}_{16}\text{H}_{10}\text{O}_4\text{Cu}$ , which is thus derived from an ene-diol. (I) heated with  $\text{SOCl}_2$  gives  $(\cdot\text{CO} \cdot \text{COPh})_n$ , which, like (I) and benzoin, is oxidised by  $\text{Cu}(\text{OAc})_2$  in aq.  $\text{AcOH}$  to benzil [ $(s\text{-C}_6\text{H}_4\text{Me}_3\text{CO})_2$  is similarly obtained from mesitoylformoin]. (I) and  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  in  $\text{MeOH}$  afford 2-phenyl-3- $\alpha$ -hydroxy- $\beta$ -keto- $\beta$ -phenylethylquinoxaline (II), m.p. 187—188°, converted by  $\text{MgPhBr}$  into 2-phenyl-3- $\alpha\beta$ -dihydroxy- $\beta\beta$ -diphenylethylquinoxaline, m.p. 163—164°, which is oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to 3-phenylquinoxaline-2-carboxylic acid and thence to 2-hydroxy-3-phenylquinoxaline (III). Acetylation of (I) with  $\text{Ac}_2\text{O}$ ,  $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$ ,  $\text{AcCl}$ , or  $\text{AcCl}-\text{C}_6\text{H}_5\text{N}$  gives 3-keto-2:4-diacetoxy-2:5-diphenyl-2:3-dihydrofuran (IV) (cf. Abenius, A., 1894, i, 286), converted by  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  in  $\text{C}_6\text{H}_6$  into the 4-hydroxy-2-acetoxy-derivative, m.p. 198°, which is reacylated to (IV) and with  $\text{MeOH}-\text{HCl}$  affords the 4-hydroxy-2-methoxy-derivative (*loc. cit.*), also obtained from the 4-acetoxy-2-methoxy-derivative (Abenius, *loc. cit.*) and  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ . Acetylation of (I) with  $\text{Ac}_2\text{O}$  in aq.  $\text{AcOH}$  yields the open-chain acetate,  $\text{OAc} \cdot \text{CHBz} \cdot \text{COBz}$ , m.p. 109—110° (or its enol), converted by  $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$  into (IV) and by  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  into (III).  $s\text{-C}_6\text{H}_4\text{Me}_3\text{COCl}$  and (I) in  $\text{C}_6\text{H}_5\text{N}$  give the di-(2:4:6-trimethylbenzoate) (V),  $\text{OR} \cdot \text{CPh} \cdot \text{C}(\text{OR}) \cdot \text{COBz}$  ( $\text{R} = s\text{-C}_6\text{H}_4\text{Me}_3\text{CO}$ ), m.p. 145°, which with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  in  $\text{MeOH}$  affords 2-phenyl-3- $\alpha\beta$ -di-(2:4:6-trimethylbenzoyloxy)styrylquinoxaline, m.p. 182—183°, oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to (III). (V) is converted by  $\text{MeOH}$ -conc.  $\text{HCl}$  into an isomeride, m.p. 189° [isolated once during prep. of (V)], which does not react with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ . 3-Keto-2:4-

dimethoxy-2:5-diphenyl-2:3-dihydrofuran with  $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$  gives the 2-acetoxy-4-methoxy-derivative, m.p. 164—165° [also obtained by acetylation of  $\text{OH} \cdot \text{CPh} \cdot \text{C}(\text{OMe}) \cdot \text{COBz}$  (*loc. cit.*)], unaffected by  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ ; the 2-acetoxy-4-ethoxy-derivative, m.p. 133°, is prepared by the same methods. Any of the above furans containing the 4-alkoxy-group is converted by  $\text{AcOH}-\text{HBr}$  into a mixture of 2-bromo-4-alkoxy-derivative (VI) (not isolable in pure condition) and 3:3'-diketo-4:4'-dialkoxy-2:5:2':5'-tetraphenyl-2:3:2':3'-tetrahydro-2:2'-difuryl (VII) (the 4:4'-dimethoxy-, m.p. 226—227°, and 4:4'-diethoxy-, m.p. 218—219°, derivatives are described). (VI) is converted by heat or acidified KI in  $\text{COMe}_2$  into (VII). The Et ether,  $\text{OH} \cdot \text{CPh} \cdot \text{C}(\text{OEt}) \cdot \text{COBz}$  (VIII) (*loc. cit.*), unlike the Me ether, gives (III) with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$ ; it is brominated to  $\text{COPh} \cdot \text{CBr}(\text{OEt}) \cdot \text{COBz}$  (Abenius, *loc. cit.*), which with acidified KI and  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  affords (VIII) and (III), respectively.

2-Phenyl-3- $\beta$ -keto- $\alpha$ -methoxy- $\beta$ -phenylethylquinoxaline is cleaved by  $\text{MeOH}-\text{NaOMe}$  to  $\text{MeOBz}$ ,  $\text{BzOH}$ , (III), and 3-phenyl-2-methoxymethylquinoxaline (IX), m.p. 78—79°; (II) similarly gives (III) and 3-phenyl-2-hydroxymethylquinoxaline, m.p. 140—141°, which is methylated ( $\text{MeI}$ , solid  $\text{NaOH}$ ) to (IX) and oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to 3-phenylquinoxaline-2-carboxylic acid. H. B.

$\alpha\delta$ -Diphenylbutane- $\alpha\beta\delta$ -trione enol; alkylation and benzoylation. R. E. LUTZ and A. H. STUART (J. Amer. Chem. Soc., 1936, 58, 1885—1890; cf. Kohler and Woodward, this vol., 1515).—Partly a correction and amplification of previous work (A., 1934, 1222, 1361).  $\alpha$ -Hydroxy- $\alpha\beta$ -dibenzoyl ethylene (I) with  $\text{BzCl}$  and a trace of conc.  $\text{H}_2\text{SO}_4$  gives 2-chloro-3-keto-2:5-diphenyl-2:3-dihydrofuran (II), hydrolysed ( $\text{MeOH}-\text{NaOH}$ ) to (I) and converted by  $\text{MeOH}-\text{NaOMe}$  into the 2-OMe-derivative (III). (II) and  $\text{AgOBz}$  in  $\text{Pr}_2\text{O}$  afford 3-keto-2-benzoyloxy-2:5-diphenyl-2:3-dihydrofuran (IV), m.p. 162—163° [also obtained from (I),  $\text{Bz}_2\text{O}$ , and a little conc.  $\text{H}_2\text{SO}_4$ ], readily hydrolysed ( $\text{NaOH}$  or  $\text{NaOMe}$ ) to (I). (I) and  $\text{BzCl}$  in aq.  $\text{NaOH}$  give  $\approx 50\%$  of  $\alpha$ -benzoyloxy- $\alpha\beta$ -dibenzoyl ethylene (or  $\gamma\delta$ -diketo- $\alpha$ -benzoyloxy- $\alpha\delta$ -diphenyl- $\Delta^a$ -butene) (V), m.p. 139°, converted by  $\text{MeOH}-\text{HCl}$  into (III) and by  $\text{Ac}_2\text{O}-\text{H}_2\text{SO}_4$  and  $\text{AcCl}-\text{H}_2\text{SO}_4$  into 3:4-diacetoxy- (VI) and 3-chloro-4-acetoxy- (VII) -2:5-diphenylfuran, respectively. (I), (II), (IV), and (VII) react immediately with  $o\text{-C}_6\text{H}_4(\text{NH}_2)_2$  in boiling  $\text{EtOH}$  yielding 2-phenyl-3-phenacylquinoxaline, m.p. 169—170° [oxidised ( $\text{CrO}_3$ ,  $\text{AcOH}$ ) to 3-hydroxy-2-phenylquinoxaline and a little 2-phenylquinoxaline-3-carboxylic acid], also obtained (on prolonged action) from  $\alpha$ -methoxy- and  $\alpha$ -amino- $\alpha\beta$ -dibenzoyl ethylene, but not from (III), (IV), (VI), and *trans*- $\alpha$ -chloro- $\alpha\beta$ -dibenzoyl ethylene. Evidence is given indicating that methylation of (I) gives the stable  $\text{COPh} \cdot \text{C}(\text{OMe}) \cdot \text{CH} \cdot \text{COPh}$  and the unstable  $\text{COPh} \cdot \text{CO} \cdot \text{CH} \cdot \text{CPh} \cdot \text{OMe}$ . It is unlikely that the colourless and yellow forms of (I) are *cis-trans* isomerides; the former is probably 2-hydroxy-3-keto-2:5-diphenyl-2:3-dihydrofuran.  $\text{CPhCl} \cdot \text{CH} \cdot \text{CO} \cdot \text{COPh}$  is (II).

The *Ag* salt of (I) with  $\text{AlkI}$  in  $\text{Pr}_2\text{O}$  gives (mainly)

2-hydroxy-3-keto-2 : 5-diphenyl-4-alkyl-2 : 3-dihydrofuran [4-Me, m.p. 143—144°, 4-Et, m.p. 113°, and 4-Pr<sup>a</sup>, m.p. 137.5°, derivatives, hydrolysed by aq. Ba(OH)<sub>2</sub> to BzCO<sub>2</sub>H and CPhEt, CPhPr, and CPhBu, respectively], and 0—20% of the  $\alpha$ -alkoxy- $\alpha$ -dibenzoyl ethylene. The Na and Ag salts of (I) with Me<sub>2</sub>SO<sub>4</sub> in MeOH and EtOH afford (III) and the 2-OEt-derivative, respectively. (I) and 2-hydroxy-1 : 4-naphthaquinone react in similar manners. All m.p. are corr.

H. B.

**Heteropolar combinations. II. Coloured "carbenium" salts of halogen acids with 4-hydroxy-2-thion-(or -oxo-)tetrahydroquinazoline and with the corresponding halogenomercuric compounds.** C. V. GHEORGHIU and (MLLE.) L. MANOLESCU (Bull. Soc. chim., 1936, [v], 3, 1830—1836; cf. this vol., 1126).—4-Ethoxy-3-phenyl-1 : 2 : 3 : 4-tetrahydroquinazol-2-one with halogen acids in Ac<sub>2</sub>O gives the *hydrochloride*, decomp. >300°, and *hydriodide*, m.p. 225°, of the 4-OH-compound, and the *hydrobromide*, m.p. 253° (decomp.), of the 4-OAc-compound; all these are yellow and therefore presumably in the carbonium state. 2-Thion-4-ethoxy-3-phenyl-1 : 2 : 3 : 4-tetrahydroquinazoline (I) similarly yields the *hydrochloride*, m.p. 225—226°, and *hydriodide*, m.p. 193—194° (red), of its 4-OH-compound, and the *hydrobromide*, m.p. 231—234° (orange), of its 4-OAc-compound. The HgCl<sub>2</sub>, HgBr<sub>2</sub>, and HgI<sub>2</sub> compounds of (I), with HBr or HI in Ac<sub>2</sub>O, give the *dihydrobromides*, m.p. 200—217°, 221°, and 207°, and the *dihydriodides*, m.p. 145°, 109—110°, and 104—105°, respectively, of 2-thiol-3-hydroxy-3-phenyl-3 : 4-dihydroquinazolinium-*S*-mercuri-dichloride, -dibromide, and -diiodide; these salts are all red in colour.

E. W. W.

**Formation of cyclic azo-compounds from 2 : 2'-diaminodiphenyls.** R. B. SANDIN and T. L. CAIRNS (J. Amer. Chem. Soc., 1936, 58, 2019—2020).—Tetrazotised 2 : 2'-diaminodiphenyl with Na<sub>3</sub>AsO<sub>3</sub> in aq. Na<sub>2</sub>CO<sub>3</sub>+CuSO<sub>4</sub> gives 45% of the cyclic 2 : 2'-azodiphenyl, m.p. 155° [the *o*-diphenyleneazone of Tauber (A., 1892, 183)]. 2 : 2'-Azo-4 : 4'-dimethyldiphenyl, m.p. 184—185°, is similarly obtained from the 2 : 2'-(NH<sub>2</sub>)<sub>2</sub>-derivative and also by reduction (Na-Hg, MeOH) of the 2 : 2'-(NO<sub>2</sub>)<sub>2</sub>-derivative.

H. B.

**Manufacture of halogenoamino-1 : 9-anthrapyrimidines.**—See B., 1936, 1084.

**Nitrogenous heterocyclic rings. XXIV. Benzodipyrroles. IV. Ring-closure with a phenylenedihydrazone.** P. RUGGLI and C. PETITJEAN (Helv. Chim. Acta, 1936, 19, 928—930; cf. this vol., 866).—Treatment of deoxybenzoin with *m*-C<sub>6</sub>H<sub>4</sub>(NH.NH<sub>2</sub>)<sub>2</sub> in boiling EtOH affords *dideoxybenzoin-m-phenylenedihydrazone*, *m*-C<sub>6</sub>H<sub>4</sub>(NH.NH.CPh.CH<sub>2</sub>Ph)<sub>2</sub>, m.p. 164°, which resinifies when heated with ZnCl<sub>2</sub> but is transformed by short treatment with boiling H<sub>2</sub>SO<sub>4</sub>-EtOH into tetraphenylbenzodipyrrole [2 : 3 : 2' : 3'-tetraphenylpyrrolo-4' : 5'-5 : 6-indole], m.p. 279°.

H. W.

**Relationship of the tricyanomelamines to polymerised dicyanamides.** J. BIECHLER (Compt. rend., 1936, 203, 568—570; cf. A., 1935, 482).—

Alkyl or aryl K cyanamides (I) with CNCl afford tricyanomelamines (cf. A., 1922, i, 438), stable at 170°. The following are prepared: *tri-phenyl-* (II), m.p. 210°, *-o-tolyl-*, m.p. 203°, *-o-*, m.p. 110°, and *-p-anisyl-*, m.p. 201°, *-p-phenetyl-*, m.p. 151°, *-naphthyl-*, m.p. 271°, *-2 : 4-xyl-yl-*, m.p. 193°, *-benzyl-*, m.p. 158°, and *-methyl-tricyanomelamine*, m.p. 241°. Deficiency of (I) in the above reaction yields chlorotriazines. The following are prepared: 4 : 6-dichloro-2-cyanoanilino-, m.p. 138—183°, and 6-chloro-2 : 4-dicyanoanilino-1 : 3 : 5-triazine, m.p. 181°, converted into 1-phenyl-3 : 5-di-*p-phenetyl-*, m.p. 115—120°, and 1 : 3-diphenyl-5-*p-phenetyl-tricyanomelamine*, m.p. 98—104°, respectively. From measurements of the heat of polymerisation of NPh(CN)<sub>2</sub> and (II), the structure of the polymeride is deduced.

J. L. D.

**Aminoflavin, 9- $\beta$ -aminoethylisoalloxazine.** P. KARRER and R. NAEF (Helv. Chim. Acta, 1936, 19, 1029—1033).—*o*-C<sub>6</sub>H<sub>4</sub>Cl.NO<sub>2</sub> and OH.CH<sub>2</sub>.CH<sub>2</sub>.NH<sub>2</sub> in boiling C<sub>5</sub>H<sub>5</sub>N give  $\beta$ -*o-nitroanilinoethyl alcohol*, m.p. 76° [Ac derivative (? acetate), m.p. 67°], transformed by PCl<sub>5</sub> in CHCl<sub>3</sub> at room temp. into *o-nitro- $\beta$ -chloroethyl-aniline*, m.p. 59°, which with *o*-C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>NK at 170° gives *o-nitro- $\beta$ -phthalimidoethyl-aniline* (I), m.p. 184°. (I) is reduced by Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub> in 50% EtOH to *o-amino- $\beta$ -phthalimidoethyl-aniline*, m.p. 124°, the *hydrochloride* of which condenses with alloxantin to 9- $\beta$ -phthalimidoethylisoalloxazine, decomp. about 285°, hydrolysed by conc. HCl-AcOH at 100° to 9- $\beta$ -aminoethylisoalloxazine *hydrochloride* (II), decomp. >300°. The alkaline solution of (II) darkens in sunlight but does not form a pigment sol. in CHCl<sub>3</sub>; in neutral solution or in presence of AcOH (II) gradually darkens without formation of > a trace of lumichrome. Photolysis of (II) therefore occurs in a more complex and incomplete manner than that of the OH-flavins.

H. W.

**Synthesis of flavins.** P. KARRER and T. H. QUTBELL (Helv. Chim. Acta, 1936, 19, 1034—1042).—*Et p-ethylphenylcarbamate*, from *p*-C<sub>6</sub>H<sub>4</sub>Et.NH<sub>2</sub> and ClCO<sub>2</sub>Et in dil. COMe<sub>2</sub>, is converted by HNO<sub>3</sub> (*d* 1.42) and conc. H<sub>2</sub>SO<sub>4</sub> at -3° to -8° into *Et 2-nitro-4-ethylphenylcarbamate*, m.p. 40.5°, which is reduced (Pt in EtOH) to *Et 2-amino-4-ethylphenylcarbamate*, m.p. 63°. The latter is transformed by *d*-ribose in boiling MeOH followed by reduction with Ni and H<sub>2</sub> at 95°/25 atm. into 2-carbethoxyamino-5-ethylphenyl-*d*-ribamine, m.p. 169°, which is hydrolysed and then converted by alloxan and H<sub>3</sub>BO<sub>3</sub> in AcOH containing NaOAc into 7-ethyl-9-*d*-1'-ribitylisoalloxazine (I), m.p. 220° after softening at 215°. 3 : 4-C<sub>6</sub>H<sub>3</sub>MeEt.NH<sub>2</sub> and *l*-arabinose yield 3-methyl-4-ethylphenyl-*l*-arabamine *hydrochloride*, m.p. 198°, whence 2-benzeneazo-5-methyl-4-ethylphenyl-*l*-arabamine, m.p. 185—186°, reduced (Ni or, preferably, Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>) to 7-methyl-6-ethyl-9-*l*-1'-arabitylisoalloxazine, decomp. 243—244°. 3 : 4-C<sub>6</sub>H<sub>3</sub>MeEt.NH<sub>2</sub> and *d*-ribose give 3-methyl-4-ethylphenyl-*d*-ribamine *hydrochloride*, whence 2-benzeneazo-5-methyl-4-ethylphenyl-*d*-ribamine, m.p. 152°, and 7-methyl-6-ethyl-9-*d*-1'-ribitylisoalloxazine (II), m.p. 238—240° after incipient decomp. when heated rapidly. 3-Naphthyl-*l*-arabamine, m.p. 156°, obtained by reduction of the condensation product,

$C_{15}H_{17}O_4N$ , decomp. 163—164°, of the sugar and  $\beta$ - $C_{10}H_9NH_2$  in boiling MeOH, is transformed into 1-benzeneazo-2-arabitylaminonaphthalene, m.p. 193°, and 5:6-benzo-9-1'-arabitylisoalloxazine, decomp. about 275°.  $\beta$ -Naphthyl-d-ribamine, m.p. 157°, affords 1-benzeneazo-2-d-ribitylaminonaphthalene, m.p. 195°, whence 5:6-benzo-9-d-1'-ribitylisoalloxazine (III), decomp. about 290°. The action of (I) on animals on a vitamin-B<sub>2</sub>-free diet is stimulating but not prolonged, whereas (II) and (III) are physiologically inactive. H. W.

**Optical absorption of porphyrins.**—See this vol., 1444.

**Manufacture of dialkyl-substituted amides of isooxazolecarboxylic acids.**—See B., 1936, 1084.

**Hydroxyquinolines. II. Synthesis of quino-linoisooxazines.** F. PIRRONI (Gazzetta, 1936, 66, 518—524).—8-Hydroxyquinoline, PhCHO, and excess of  $NH_3$  in EtOH give a substance,  $C_{23}H_{28}ON_2$ , m.p. 156—157°. This is decomposed by boiling dil. HCl with liberation of PhCHO and formation of a cryst. substance, forms a picrate, m.p. 220—221°, and Ac, m.p. 208—209°, and Bz, m.p. 196—197°, derivatives, but gives no metallic

compounds or reactions of 8-hydroxyquinoline; it is therefore probably 2:4-diphenyl-5:6-(7':8'-quinolino)-1:3-isooxazine (A). E. W. W.

**Manufacture of sulpheneamides.**—See B., 1936, 1083.

**1-Methyl- $\beta\beta'$ -naphthathiazole and substitution products.**—See B., 1936, 977.

**Constitution of oryzanin (vitamin-B<sub>1</sub>).** T. IMAI (Z. physiol. Chem., 1936, 243, II; cf. this vol., 487).—Aneurin (I) and thiochrome (II) contain two CMe groups and in (I) there is a  $CH_2$  bridge between the thiazole and pyrimidine nuclei. KSH with 8-chloro- or 8-bromo-theophylline gives 8-thiotheophylline, which with  $CH_2Cl\cdot COMe$  gives the compound  $NMe\cdot CO\cdot C\equiv N\cdot CMe\cdot S\equiv CH$  which exhibits no blue fluorescence. (I) is almost quantitatively converted by  $H_2SO_3$  into 4-amino-2-methyl-5-pyrimidylsulphonic acid and 4-methyl-5- $\beta$ -hydroxyethylthiazole. Hence (I) and (II) are

W. McC.

**Aneurin. III. Methyl  $\alpha$ -chloro- $\gamma$ -hydroxypropyl ketone and its application to thiazole synthesis.** A. R. TODD, F. BERGEL, and (Miss) A. JACOB. IV. 5-Thioformamidopyrimidines. A. R. TODD, F. BERGEL, and KARIMULLAH. V. Synthesis of 3-pyrimidylthiazolium salts, including an isomeride of aneurin. A. R. TODD and F. BERGEL (J.C.S., 1936, 1555—1557, 1557—1559, 1559—1562).—III.  $OAc\cdot[CH_2]_2\cdot CHAc\cdot CO_2Et$  with  $SO_2Cl_2$  gives Et  $\alpha$ -chloro- $\alpha$ - $\beta'$ -acetoxethylacetoacetate, b.p. 120—121°/2 mm., which with  $H_2SO_4$ -AcOH

forms Me  $\alpha$ -chloro- $\gamma$ -acetoxypyrrol ketone, b.p. 85—92°/16 mm. The ketone with thioformamide is converted into 4-methyl-5- $\beta$ -hydroxyethylthiazole, the picrate, m.p. 162—163°, of which is identical with that obtained from aneurin (vitamin-B<sub>1</sub>). Et  $\alpha$ - $\beta'$ -phenoxyethylacetoacetate, b.p. 148°/4 mm., prepared from  $OPh\cdot CH_2\cdot CH_2Br$  and Et sodioacetoacetate, with  $SO_2Cl_2$  affords Et  $\alpha$ -chloro- $\alpha$ -2-phenoxyethylacetoacetate, b.p. 135—140°/3 mm., hydrolysed to Me  $\alpha$ -chloro- $\gamma$ -phenoxypropyl ketone, b.p. 168—172°/12 mm., which with  $NH_2\cdot CSMe$  gives 2:4-dimethyl-5- $\beta$ -phenoxyethylthiazole (picrate, m.p. 122°).

IV. 5-Amino- with dithioacetic acid yields 5-thioacetamido-, m.p. 265—267°, and with dithioformic acid affords 5-thioformamido-4-methyluracil, m.p. 260—262°, which with  $CH_2Cl\cdot COMe$  gives 3-(2':6'-dihydroxy-4'-methylpyrimidyl-5')-4-methylthiazolium chloride, m.p. 306° (decomp.). 6-Amino-5-thioformamido-4-methylpyrimidine gives 4-methylpurine at its m.p. 168°. 2-Amino-6-hydroxy-4-ethylpyrimidine, m.p. 247—248°, prepared from Et propionylacetate and guanidine carbonate, with  $PCl_3$  gives 6-chloro-2-amino-, m.p. 120—121°, converted ( $NH_3$ ) into 2:6-diamino-4-ethylpyrimidine, m.p. 160—161°. Thioformylation (K dithioformate) affords 6-amino-, m.p. 178°, and 2:6-diamino-5-thioformamido-4-methylpyrimidine, m.p. 255°, which is converted ( $CH_2Cl\cdot COMe$ ) into 3-(2':6'-diamino-4'-methylpyrimidyl-5')-4-methylthiazolium chloride hydrochloride ( $+3H_2O$ ), m.p. 255°.

V. 6-Amino-5-thioformamido-4-ethylpyrimidine and Me  $\alpha$ -chloro- $\gamma$ -hydroxypropyl ketone give 3-(6'-amino-4'-ethylpyrimidyl-5')-4-methyl-5- $\beta$ -hydroxyethylthiazolium chloride hydrochloride ( $+H_2O$ ), m.p. 220° (decomp.), which is not identical with aneurin hydrochloride, and shows no measurable physiological activity, in common with the following: 3-(6'-amino-4'-ethylpyrimidyl-5')-4-methylthiazolium chloride hydrochloride, m.p. 252—253° (decomp.), 3-(6'-amino-4'-methylpyrimidyl-5')-4-methyl-5- $\beta$ -hydroxyethylthiazolium chloride hydrochloride ( $+H_2O$ ), m.p. 250° (decomp.), and 4-methylthiazolium chloride hydrochloride ( $+2H_2O$ ), m.p. 254—255° (decomp.). 2:6-Dihydroxy-8-thiopurine with  $CH_2Cl\cdot COMe$  yields 2:6-dihydroxy-4-methylthiazolo-(2':3':8:7)-purine, m.p. >250°, but 8-thio-6-ethylpurine, m.p. >300°, does not condense satisfactorily with chloroketones. The structure of aneurin is discussed. F. R. S.

**Lupin alkaloids. XI. Octahydropyridocoline-norlupinane relationship.** G. R. CLEMO, T. P. METCALFE, and R. RAPER (J.C.S., 1936, 1429—1431).—Et 2-methylpyrrolidine-5-acetate,  $CH_2Cl\cdot CH_2\cdot CO_2Et$ , and NaOAc give Et 2-methylpyrrolidine-5-acetate-1- $\beta$ -propanate, b.p. 168—169°/14 mm., which is cyclised (K) to 7-keto-3-methyloctahydropyrrocoline, b.p. 72—75°/1 mm. (picrate, m.p. 204°), reduced (Wolff) to 3-methyloctahydropyrrocoline and a substance, b.p. 95°/1 mm. [picrolonate, m.p. 245° (decomp.)]. Me piperidine-2-acetate,  $CH_2Cl\cdot CH_2\cdot CO_2Me$ , and NaOAc afford Me piperidine-2-acetate-1- $\beta$ -propanate, b.p. 170—172°/1 mm., cyclised (K) to 2-keto-octahydropyridocoline, b.p. 70—72°/1 mm. (picrate, m.p. 211°), which is reduced (Zn-Hg) to norlupinane, also obtained by reduction (Wolff) of 1-keto-octahydropyridocoline.

These results support the *cis-trans* formulation of octahydropyridocoline and norlupinane.

F. R. S.

**Electrolytic reduction of vasicine.** K. S. NARANG and J. N. RAY (J.C.S., 1936, 1570).—The substances reported (this vol., 869) to be dissimilar are now shown to be identical.

F. R. S.

**Ambaline, a new alkaloid from *Pycnarrhena manillensis*, Vidal.** G. Q. QUIBILAN and A. C. SANTOS (Univ. Philippines Nat. Appl. Sci. Bull., 1933, 3, 353—364).—*Ambaline*,  $C_{38}H_{52}O_{10}N_2$ , m.p. 123°,  $[\alpha]_D +143.2^\circ$  in  $CHCl_3$  [*aurichloride*, m.p. 185° (decomp.); *platinichloride*, m.p. 260°; *dihydrochloride*, m.p. 265°; *dihydrobromide*, m.p. 195—197° (decomp.); *dihydriodide*, m.p. 245° (decomp.); *methiodide*, m.p. 263°; *oxime*, m.p. 197° (decomp.); 2:4-dinitrophenylhydrazones, m.p. 96°], has been isolated and its colour reactions determined. It contains  $\cdot CH_2O_2$ , CO, 3 OMe, and 2 NMe, and is toxic.

F. R. S.

**Ambalinine, a new non-phenolic alkaloid from *Pycnarrhena manillensis*, Vidal.** I. VILLANOS and A. C. SANTOS (Univ. Philippines Nat. Appl. Sci. Bull., 1935, 4, 338—341).—A non-phenolic alkaloid, *ambalinine*,  $C_{15}H_{12}O(OMe)_2 \cdot NMe$ , m.p. 203—204° [*platinichloride*, m.p. 240° (decomp.); *aurichloride*, m.p. 170° (decomp.); *picrate*, m.p. 238° (decomp.)], has been isolated.

F. R. S.

**Alkaloids of *Corydalis ambigua* of China, Cham et Sch. (Yen-hu-So). VI. Identification of corydalis D and M.** T. Q. CHOU (Chinese J. Physiol., 1936, 10, 507—511).—*Corydalis D* (I),  $C_{19}H_{17}O_4N$ ,  $[\alpha]_D -305^\circ$ , was oxidised by I in EtOH to a *quaternary iodide*, m.p.  $>300^\circ$ , reduced by Zn- $H_2SO_4$  to *dl-tetrahydrocoptisine*, m.p. 220°. (I) is therefore the *l*-isomeride of this substance. *Corydalis M*,  $C_{21}H_{23}O_5N$ , m.p. 160°, optically inactive, contains 2 OMe and 1  $CH_2O$ , and is probably identical with  $\beta$ -homochelidonine.

P. W. C.

**Microscopic investigation of alkaloids in ergot. I. Ergotamine and ergotaminine.** A. KOFLER (Arch. Pharm., 1936, 274, 398—414).—The compound of ergotamine with  $2COMe \cdot 2H_2O$  (cf. Stoll, A., 1923, i, 127), m.p. 172—174°, and *compounds* with  $H_2O$ , m.p. 174—176°,  $C_5H_5N$ , m.p. 172—176°, MeOH, m.p. 208—210° (decomp.), and EtOH, m.p. 208—210°, form monoclinic crystals; *compounds* with  $C_6H_6$ , m.p. 168—172°, and  $(CH_2Cl)_2$ , m.p. 182—186°, are rhombic. *Compound* with  $Et_2O$ , m.p. 183—185°.  $n_D$  for the axes of these compounds and ergotaminine are recorded.

F. R. G.

**Alkaloids of ergot. VII. isoErgine and isolysergic acids.** S. SMITH and G. M. TIMMS (J.C.S., 1936, 1440—1444).—The laevorotatory physiologically active ergot alkaloids can be transformed readily into alkaloids of high dextrorotation with weak physiological action and the change is readily reversed. Ergine can be converted ( $EtOH-H_3PO_4$ ) into *isoergine* (I), m.p. 242° (decomp.),  $[\alpha]_{541}^{20} +25^\circ$  in  $C_5H_5N$  [*hydrochloride*, m.p. 269° (decomp.)]. (I) is hydrolysed to lysergic acid (II), which is converted by hot  $H_2O$  into *isolysergic acid* ( $+2H_2O$ ), m.p. 218° (decomp.)  $[\alpha]_{461}^{20} +368^\circ$  in  $C_5H_5N$  [*nitrate* ( $+H_2O$ ), m.p.

185° (decomp.); *Me ester*, m.p. 170° (decomp.),  $[\alpha]_{541}^{20} +236^\circ$  in  $CHCl_3$ ], reconverted into (II) by aq. KOH. (II) with  $Ba(OH)_2$  yields *inactive lysergic acid* ( $+2H_2O$ ), m.p. 250° (decomp.) [*Me ester*, m.p. about 160° (decomp.)], which cannot be reconverted into (II).

F. R. S.

**Alkaloids from *Solanum pseudocapsicum*, L.** G. BARGER and H. L. FRAENKEL-CONRAT (J.C.S., 1936, 1537—1542).—*Solanocapsine* (I),  $C_{26}H_{41}O_2N_2 \cdot H_2O$ , m.p. 222°,  $[\alpha]_D +25.5^\circ$  [*dihydrochloride* ( $+H_2O$ ), m.p.  $>280^\circ$ ; *Ac*<sub>2</sub> derivative, m.p. 150—160°] is dehydrated to *aposanocapsine*, with  $HNO_2$  forms a *NO-compound* (II), m.p. 194° ( $H_2$ -derivative, m.p. 211—212°), and with  $COMe$  yields a *compound*, m.p. 233°, which with  $Ac_2O$  affords *monoacetylsolanocapsine*, m.p. 238°. Oxidation of (II) gives an *acid*, m.p. 226—227°, and a *neutral substance*, m.p. 218°. *Solanocapsidine*,  $C_{26}H_{42}O_4N_2$ , m.p. about 305°, is dehydrogenated (Se) to methylcyclopentenophen-

anthrene, 2-methyl-5-ethylpyridine (*picrate*, m.p. 163°), and 4-methyl-2-ethylpyridine (?) (*picrate*, m.p. about 125°). On the basis of the reactions the formula for (I) is suggested.

The two bases may be secondary products, formed during isolation.

F. R. S.

**Anodic oxidation of brucine and nicotine.** F. FICHTER and H. STENZL (Helv. Chim. Acta, 1936, 19, 1171—1175).—Electrolytic oxidation of brucine in  $H_2SO_4$  at a  $PbO_2$  anode affords dehydrobisapomethylbrucine,  $C_{21}H_{22}O_4N_2$ , or, if reaction is prolonged, a red-brown base. Electrolytic chlorination of brucine yields a mixture of substances,  $C_{21}H_{27}O_7N_2Cl_7$ . Nicotinic acid is obtained by electrochemical oxidation of nicotine in  $H_2SO_4$  at a Pt anode. The products are therefore identical with those obtained by purely chemical methods.

H. W.

**Manufacture of deoxymorphine-C and dihydromorphine-D.**—See B., 1936, 1018.

**Structure and toxicity of arsinic acids of the diphenylamine series.** V. A. ISMAILSKI and A. M. SIMONOV (Bull. Soc. chim., 1936, [v], 3, 1739—1753).—The introduction of OH or NHAc at 4' in 2-nitro- or 2-amino-diphenylamine-4-arsinic acid (A., 1934, 1118) reduces the toxicity, and a similar and greater effect (especially of OH) is produced at 3'. Reduction of toxicity is less with 4'-OMe than with 4'-OH, and still less with 4'-OEt. The use of the effect of substituents to reduce toxicity of arsinic acids for pharmacological use is suggested, and the electronic transmission of the effect to the  $AsO_3H_2$  group is discussed. The following are prepared. From 4-chloro-3-nitrophenyl-arsinic acid (I) and  $NH_2R$ : 2-nitro-3'- (II) and -4'-acetamido- (III), -4'-hydroxy- (IV), -4'-ethoxy- (V), -3'-hydroxy- (VI), -4'-methoxy-, and -2'-methoxy-diphenylamine-4-arsinic acid. From (II), (III), (IV), and (V), using  $Na_2S_2O_4$ : 2-amino-3'- and -4'-acetamido-, -4'-hydroxy-, and -4'-ethoxy-diphenylamine-4-arsinic acid. [The  $NH_2$ -compound from (VI) could not be isolated.] From 2-nitro-diphenylamine-4-arsinic acid, the 2-amino-acid. 6-Chloro-3-nitro-

*phenylarsinic acid* (obtained from 6-chloro-3-nitro-aniline) gives resinous condensation products. (I) and benzidine yield 3-nitro-4-benzidinophenylarsinic acid. E. W. W.

**Manufacture of arsenobenzenesulphoxylates.**—See B., 1936, 1018.

**Manufacture of arsenic compounds of the naphthaquinone series.**—See B., 1936, 1018.

**Relative activities of organo-metallic compounds. XIII. Copper and silver.** H. GILMAN and J. M. STRALEY (Rec. trav. chim., 1936, 55, 821—834; cf. this vol., 1279).—MgPhI and CuI in Et<sub>2</sub>O at 0° give 86% of CuPh, which, besides the known reactions, with AcCl gives 66% of COPhMe, with BzCl 55% of COPh<sub>2</sub>, with CH<sub>2</sub>:CH·CH<sub>2</sub>Br 31% of CH<sub>2</sub>Ph·CH:CH<sub>2</sub>, with H<sub>2</sub>O 36% of C<sub>6</sub>H<sub>6</sub>, and with PhNCO 14% of NHPhBz with, in most cases, much Ph<sub>2</sub>. With other reagents only Ph<sub>2</sub> is obtained. Cu *p*-anisyl was also prepared, but is as unstable as CuPh. Cu ethyl is stable only in solid CO<sub>2</sub>-Et<sub>2</sub>O, but the solution gives reactions similar to those of CuPh. Ag phenyl is prepared in Et<sub>2</sub>O at -18°, but cannot be isolated; its prep. is accelerated by light. Its reactions resemble those of CuPh, but yields are usually lower. These and similar results are discussed. The order of stability and of decreasing reactivity of MR is M=Cu>Ag>Au, R=aryl>alkyl, and of decreasing reactivity ZnR<sub>2</sub>>CuPh>HgR<sub>2</sub>. R. S. C.

**Phenylmercury nitrate and some other phenylmercury salts.** T. B. GRAVE, S. E. HARRIS, and W. G. CHRISTIANSEN (J. Amer. Pharm. Assoc., 1936, 25, 752—756).—Hg Ph nitrate, from the acetate and NaNO<sub>3</sub>, is HgPh·OH, HgPh·NO<sub>3</sub>; in presence of C<sub>5</sub>H<sub>5</sub>N, a compound, HgPh·NO<sub>3</sub>·C<sub>5</sub>H<sub>5</sub>N, m.p. 182—183°, is formed. Aq. Hg Ph hydroxide with the appropriate acid affords Hg Ph lactate, m.p. 160—161°, basic gluconate, m.p. 171—172° (decomp.), phenolsulphonate, m.p. 162—164° (decomp.), and hydroxybutyrate, m.p. 149—149.5° (decomp.). F. O. H.

**Mercury compounds containing nitrogen [bactericides and fungicides].**—See B., 1936, 1019.

**Relative reactivities of organometallic compounds. XIV. Orientation in metalation.** H. GILMAN and R. H. KIRBY (J. Amer. Chem. Soc., 1936, 58, 2074—2075).—Prolonged interaction of HgEt<sub>2</sub> (0.02 g.-mol.) and K (0.08 g.-atom) in C<sub>6</sub>H<sub>6</sub> (35—75 c.c.) gives C<sub>6</sub>H<sub>5</sub> (with small amounts of H<sub>2</sub> and C<sub>2</sub>H<sub>4</sub>), KPh, and *o*- and *p*-C<sub>6</sub>H<sub>4</sub>K<sub>2</sub>, since subsequent treatment with CO<sub>2</sub> affords BzOH (33—45%) and *o*- and *p*- (14—17%) -C<sub>6</sub>H<sub>4</sub>(CO<sub>2</sub>H)<sub>2</sub>; KPh appears to be formed thus: C<sub>6</sub>H<sub>6</sub>+KEt→KPh+C<sub>2</sub>H<sub>6</sub>. KPh is *o*-*p* orienting. The order of reactivity KEt>NaEt>LiEt (no reaction), has been established. H. B.

[Organic compounds of tin.] M. K. KOZESCHKOV (Bull. Soc. chim., 1936, [v], 3, 2069—2070).—A claim for priority against Lesbre (A., 1935, 966). H. W.

**Arylstannonic acids and their halogenated derivatives.** M. LESBRE (Bull. Soc. chim., 1936, [v],

3, 2071—2072).—A reply to Kozeschkov (preceding abstract). H. W.

**Separation of amino-acids by means of their copper salts. II. Investigation of the methyl alcohol-soluble copper salt fraction, and the yield of protein from gliadin.** B. W. TOWN (Biochem. J., 1936, 30, 1837—1844).—The Cu salts of NH<sub>2</sub>-acids from proteins can be separated into three fractions: (a) those sol. in MeOH and H<sub>2</sub>O, (b) those insol. in MeOH, sol. in H<sub>2</sub>O, (c) those insol. in MeOH or H<sub>2</sub>O. From gliadin 97% of the total N is accounted for in these fractions. The CdCl<sub>2</sub> ppt. from (a) contains mainly proline; the amount corresponds with a proline content in gliadin of 10.3%. This val. is > that obtained by isolation, but < that corresponding with total non-NH<sub>2</sub>-N; this is due to the presence of diketopiperazines. F. A. A.

**Micro-determination of glycine in protein hydrolysates.** B. W. TOWN (Biochem. J., 1936, 30, 1833—1836).—3 : 6-Dinitro-2 : 5-dihydroxy-*p*-benzoquinone (I) (prep. given) is a sp. precipitant for glycine, in the absence of inorg. cations. Using (I) the glycine content of gelatin is found as 25.5%, but the data for caseinogen indicate a glycine content of 3.4—3.7%. F. A. A.

**Spectrophotometry of proteins. I. Absorption spectra of tyrosine, tryptophan, and their mixtures. II. Determination of tyrosine and tryptophan in proteins.** E. R. HOLIDAY (Biochem. J., 1936, 30, 1795—1803).—The absorption curves of tyrosine (I) and tryptophan (II) are determined between 260 and 305 mμ in acid, neutral, or alkaline solution, and a method for determination of their concns. in mixtures of the two is described. Determination of (I) and (II) in 5 mg. of protein by this method is described and the results are compared with those by chemical analysis. The errors of the method and a means of correcting for pigment impurities are discussed. P. W. C.

**Diazotization of proteins.** H. EAGLE (Proc. Soc. Exp. Biol. Med., 1936, 34, 39—40).—The colour which many proteins give when treated with HNO<sub>2</sub> and coupled with aromatic amines or phenols in presence of alkali is probably due in part to the presence of tryptophan. W. O. K.

**Iodine [in protein].** E. NOLTE (Arch. Pharm., 1936, 274, 415—418).—Hydrolysis of iodoprotein with Sr(OH)<sub>2</sub> gives an active product (14% I) resembling that given by Ba(OH)<sub>2</sub> (cf. Mattis, A., 1931, 1463). Ca(OH)<sub>2</sub> and superheated steam do not give an active product. F. R. G.

**Hydrogen bond and the structure of proteins.** D. M. WRINCH and D. J. LLOYD (Nature, 1936, 138, 758—759; cf. this vol., 619).—Possible structural formulæ using the H linking as the mechanism whereby laminar protein mols. are formed from closed polypeptides are elaborated. L. S. T.

**Semi-micro-determination of carbon in organic compounds.** J. A. SANCHEZ (J. Pharm. Chim., 1936, [viii], 24, 297—310).—The compound is heated with solid KMnO<sub>4</sub> in a sealed tube and the CO<sub>2</sub>, collected initially in NaOH, is liberated quantitatively

with 25%  $\text{H}_3\text{PO}_4$  and distilled into standard NaOH containing  $\text{BaCl}_2$ . J. L. D.

**Determination of carbon and hydrogen by semi-micro-combustion.** E. V. ZAPPI and R. LABRIOLA (Anal. Asoc. Quím. Argentina, 1936, 24, 47—50).—Satisfactory results are obtained in the combustion of 20—30 mg. of material using the method of Berger (A., 1932, 410). F. R. G.

**Selective combustion of hydrogen, carbon monoxide, and methane by palladium catalysts.**—See this vol., 1472.

**Determination of vanillin with 2:4-dinitrophenylhydrazine.** N. RUBIN and A. BLOOM (Amer. J. Pharm., 1936, 108, 387—388).—Contrary to Iddles *et al.* (A., 1935, 101) a technique is described whereby vanillin may be accurately determined (99.44%)

gravimetrically as its 2:4-dinitrophenylhydrazone even in presence of 10% EtOH. J. W. B.

**Extremely sensitive reaction for some nitro-genous bases.** H. WACHSMUTH (J. Pharm. Belg., 1935, 17, 795—798; Chem. Zentr., 1936, i, 379).—Morphine, pyramidone, apomorphine, and adrenaline give sensitive colour reactions (described) with  $\text{CuSO}_4$  and  $\text{CN}'$ ,  $\text{SCN}'$ ,  $\text{Fe}(\text{CN})_6'''$ , or nitroprussides. H. N. R.

**Determination of nicotine.** W. HAMMERLE and W. WEBER (Mitt. Lebensm. Hyg., 1936, 27, 46—48).—The silicotungstic acid method is preferred, but the nicotine should be liberated originally from 2 g. of sample in 40 c.c. of  $\text{H}_2\text{O}$  with 5 c.c. of 30% NaOH; 2 c.c. of 10% reagent per 250 c.c. of distillate should be used for pptn., which is complete after 5 min. at  $80^\circ$  and 3 hr. in the cold. J. G.

## Biochemistry.

**Role of the vagus in the automatic regulation of respiration.** W. HESS (Pflüger's Arch., 1936, 237, 24—39).—Disagreement between the author's previous results and those of ter Braak and van Niekerk is explained. M. A. B.

**Physiological effects of high pressures.** L. A. SHAW (J. Ind. Hyg., 1936, 18, 486—496).—Pulmonary emboli can be absorbed by breathing  $\text{O}_2$  under 3 atm. pressure without harmful effect. "Compressed air disease" is caused by the accumulation of  $\text{N}_2$  bubbles in the venous circulation following exposure to high pressures. P. G. M.

**Biological importance of phosphate esters of red corpuscles.** E. FREUDENBERG (Z. Kinderheilk., 57, 427—441; Chem. Zentr., 1936, i, 100).—Arterialisation of blood inhibits phosphatolysis. P esters of erythrocytes in conjunction with phosphatase control the level of blood-P, and form a P reserve which in acidosis serves to eliminate  $\text{H}^+$ . P ester content of erythrocytes is lowered in rickets but increases after sp. therapy. A. G. P.

**Secretin XI: its effect on the reticulocytes of the circulating blood.** J. FERGUSON (Endocrinol., 1936, 20, 683—684). R. N. C.

**Physico-chemical properties of hæmocyanins. IV. Variation in the osmotic pressure of hæmocyanin during prolonged inanition.** A. ROCHE and J. ROCHE (Bull. Soc. Chim. biol., 1936, 18, 1503—1512).—Determinations of osmotic pressure show that during hibernation of *Helix pomatia* and aestivation of *H. pisana* the mol. wt. of the hæmocyanin considerably decreases. The physiological significance of this is discussed. A. L.

**Serum-bilirubin content of the blood of rats consuming a ration deficient in inorganic salts.** J. M. ORTEN and A. H. SMITH (Proc. Soc. Exp. Biol. Med., 1936, 34, 72—74).—The bilirubin content of the blood of rats on a diet deficient in inorg. salts, and in consequence exhibiting a polycythæmia, does not differ significantly from that of controls. The polycythæmia is therefore not the result of abnormally slow erythrocyte destruction. W. O. K.

**Micro-potentiometric titrations of normal horse serum-globulins.** A. G. OGSTON (Biochem. J., 1936, 30, 1845—1848).—A method using only 0.4—0.6 ml. of 0.5% protein solution is described. The titres of horse serum-pseudoglobulins (I) are < those of the euglobulins (II). The variation between individual samples is greater for (II). Both proteins after drying, and (II) after  $(\text{NH}_4)_2\text{SO}_4$  pptn., give abnormal curves and indicate increased polydispersion in solution.  $\text{CH}_2\text{O}$  titration indicates that any new groups so formed are not  $\text{NH}_2$ , and that the greater titre of (II) is not due to  $\text{NH}_2$ . There is no apparent correlation between the titres and the tyrosine content. F. A. A.

**Constituents of acid globulins. Protein C.** M. DOLADILHE (Ann. Inst. Pasteur, 1936, 57, 443—462).—Flocculation of sera produced by dilution with acidulated  $\text{H}_2\text{O}$  is mainly due to the effect of the  $p_{\text{H}}$  on the acid globulin fraction rather than to lowered salt concn.; the flocculation frequently produced by distilled  $\text{H}_2\text{O}$  is effected by dissolved  $\text{CO}_2$ , the ppt. consisting of acid globulins. The application of these facts to the flocculation of syphilitic sera is considered. Details of the prep. and the effect of heat on the physical properties of protein C are given (cf. this vol., 875). P. G. M.

**Biochemistry of serum irradiated with artificial light. VIII. Analysis of serum-protein.** M. MURAYAMA (J. Orient. Med., 1936, 24, 79—80).—Irradiation with ultra-violet light or with X-rays caused a small decrease in the total N and albumin-N, but an increase in the globulin-N in human serum. NUTR. ABS. (m)

**Limits of the reaction for determination of the tyrosine index of serum-polypeptides.** V. CIO-CALTEU and G. TANASESCO (Compt. rend. Soc. Biol., 1936, 123, 49—50).—A modified method utilising the Folin-Ciocalteu reagent (A., 1927, 892) is proposed since that of Goiffon and Spacy (A., 1935, 374) is accurate over only a narrow range. H. G. R.

**Nucleotide-nitrogen content of human leucocytes.** F. W. ALLEN, S. P. LUCIA, and J. J. EILER

(Proc. Soc. Exp. Biol. Med., 1936, 34, 609—611).—In cases of myeloid leucæmia with high leucocyte counts the nucleotide-N of the leucocytes is  $>50\%$  of the total. The nucleotide content of whole blood decreases with a regression of the leucocyte count, when the erythrocyte count is const. P. G. M.

**Quantitative isolation of histamine and tyramine from plasma and serum.** A. SCHWARTZ and A. RIEGERT (Compt. rend. Soc. Biol., 1936, 123, 219—223).—Adsorption on Permutit is followed by elution with saturated aq. NaCl. H. G. R.

**Determination of the urea content of blood-serum.** P. SORGDRAGER (Pharm. Tijds. Nederl.-Indie, 1935, 12, 241—243; Chem. Zentr., 1936, i, 125).—An improved apparatus for, and corrections to be applied to results obtained by, van Assenraad's method (A., 1929, 1326) are described. H. N. R.

**Normal phenol content of blood.** M. CASTEX and A. ARNAUD (Publ. méd., 1935, 1, No. 3).—In normal blood vials. were: free phenols (I) 1—1.3, total (I) 1.1—1.4, conjugated (I) 0—0.3 mg. per 100 c.c. Normal variations are small even when large amounts of (I) are eliminated in urine.

CH. ABS. (p)

**Determination of fat in 0.1 c.c. of blood or serum.** G. SURANYI and P. VÉGHELYI (Magyar orvosi Arch., 1935, 36, 169—175; Chem. Zentr., 1936, i, 391—382).—Total fat is extracted with 15 c.c. of EtOH, and total fat without lecithin with COME<sub>2</sub>, each from 0.05 c.c. of blood. The solutions are brought to 10 c.c., and 2 c.c. are slowly treated with 5 c.c. of 10% HCl+1% of BuOH. The turbidity produced is measured photometrically. J. S. A.

**Partition of reduced ascorbic acid in blood.** D. J. STEPHENS and E. E. HAWLEY (J. Biol. Chem., 1936, 115, 653—658).—The content in human white blood cells is  $>$  that in whole blood, plasma, or red cells. Abnormally high vals. in the whole blood of leucæmic patients are due to the high leucocyte count. F. O. H.

**Determination of reduced ascorbic acid in small amounts of blood.** C. J. FARMER and A. F. ABT (Proc. Soc. Exp. Biol. Med., 1936, 34, 146—150).—The method enables the ascorbic acid content of 0.3 ml. of blood to be determined by titration from a special micro-burette, with 2:6-dichlorophenol-indophenol. HPO<sub>4</sub> is used for deproteinisation.

W. McC.

**Influence of muscular action on blood-sugar and -catalase.** H. KOEPPE (Klin. Woch., 1935, 14, 667—670; Chem. Zentr., 1936, i, 372).—Blood-sugar and -catalase contents are changed simultaneously and in opposite directions after carbohydrate feeding, during fasting, and during muscular activity.

A. G. P.

**Hyperglycæmia and augmentation of the undetermined carbohydrate of the plasma following experimental shock in the dog.** O. LAMBRET, G. BIZARD, and J. DRIESSENS (Compt. rend. Soc. Biol., 1936, 123, 413—415).—The phenomena appear to be connected with the adrenal gland. H. G. R.

**Effect of hypophysectomy on blood-sugar in Rhesus monkeys.** P. E. SMITH, L. DOTTI, H. H.

TYNDALE, and E. T. ENGLE (Proc. Soc. Exp. Biol. Med., 1936, 34, 247—249).—After fasting, hypophysectomy reduced the sugar content of the blood from 90—100 to 20—90 mg. per 100 c.c.

W. McC.

**Determination of small amounts of carbon monoxide in blood.** H. BURESCH and V. LUNIATSCHEK (Arch. Gewerbepath. Gewerbebyg., 1936, 7, 182—191).—An improved apparatus (cf. A., 1934, 1241) is described. M. A. B.

**Residual nitrogen of the blood and its principal components.** I. Normal distribution. P. LARIZZA (Arch. exp. Path. Pharm., 1936, 182, 617—632).—Data for the total residual (i.e., non-protein) N (I) and its distribution in human blood are tabulated. The average distribution-ratios between corpuscles and serum are: total (I) 1.75, urea-N 0.70, NH<sub>2</sub>-N 1.71, total creatinine-N 1.67; that of uric acid-N is irregular. The undetermined (I) in serum was 15% and in corpuscles 44% of the total (I). F. O. H.

**Calcium and inorganic phosphorus content of blood-serum of swine.** E. H. HUGHES (J. Agric. Res., 1936, 53, 267—279).—Serum-Ca and -inorg. P in young pigs were  $>$  in older ones. Immediately before and after farrowing Ca vals. increased and those of P declined, in comparison with those for non-pregnant sows. Ingestion of Ca increased serum-Ca temporarily, a prolonged increase (with simultaneous decrease in inorg. P) following continuous feeding of large proportions of CaCO<sub>3</sub>. Continuous feeding of a Ca-deficient diet lowered serum-Ca, the -inorg. P being increased in mature but decreased in young animals. Low serum-Ca caused Ca tetany.

A. G. P.

**Copper and iron in human blood.** IV. Normal children. A. SACHS, V. E. LEVINE, and A. A. FABIAN (Arch. Int. Med., 1936, 58, 523—530).—Cu varies inversely as Fe in the blood of normal children. The blood of the new-born contains Fe, 51.79 mg., Cu,  $83 \times 10^{-6}$  g. per 100 c.c.; in an age group 1½ months—15 years the figures were Fe, 40.51 mg., Cu,  $171 \times 10^{-6}$  g.

P. G. M.

**Effect of boiler-makers' work on the composition and properties of their blood. Water shift between blood and tissues and between serum and cells.** MEER S. MISCHKIS and MARIA S. MISCHKIS (Ukrain. Biochem. J., 1936, 9, 369—380).—The H<sub>2</sub>O content of blood cells of workers in all branches of the trade increases by 0.7—1.4% towards the end of the day. No increase in H<sub>2</sub>O content of serum is found. The H<sub>2</sub>O content of whole blood, serum, and blood cells of boiler sweeps is  $>$  that of other boiler workers. These effects are contrary to those observed during short periods of strained work. F. A. A.

**Determination of blood- $p_H$  by the glass electrode.** V. Glass micro-electrode and the  $p_H$  of arterial, venous, and capillary blood. H. YOSHIMURA (J. Biochem. Japan, 1936, 23, 335—350; cf. this vol., 682).—A glass electrode, applicable to 0.07 c.c. and accurate to 0.02  $p_H$ , is described. Direct measurements on rabbits and examination of blood removed from men show that the  $p_H$  of arterial blood

equals that of capillary but is  $>$  that of venous blood by approx. 0.03. F. O. H.

**Preservation of sera by desiccation in the frozen state without the use of refrigerants.** R. I. N. GREAVES and M. E. ADAIR (J. Hyg., 1936, 36, 507—513).—Antisera are desiccated after freezing by rapid evaporation in a high vac. over  $P_2O_5$ . Preliminary evacuation of the sera in the absence of the drying agent overcomes violent frothing. The method can be applied to the drying of bacteria. W. L. D.

**Food allergy.** A. W. OELGOETZ, P. A. OELGOETZ, and J. WITTEKIND (Amer. J. Digest. Dis. Nutrition, 1934, 1, 730—737).—Hypersensitiveness to foods is probably caused by excess of free food (free from enzymes) in the blood-serum, this excess being due to a low pancreatic threshold. CH. ABS. (p)

**Blood-groups and -radiation.** W. W. SIEBER and H. SEFFERT (Biochem. Z., 1936, 287, 109—112).—The blood of a normal healthy man is strongly mitogenetic. When the same amount of blood of two individuals is mixed *in vitro*, the mixed blood is mitogenetic only when it results from a combination of definite blood-groups. Mixtures of bloods from the same blood-groups, of group O with another group, and of group AB with another group, remain active, but those of group A with group B are inactive. P. W. C.

**Hæmolysis produced by small variations in  $p_H$ .** R. VAVRA (Compt. rend. Soc. Biol., 1936, 123, 161—163).—The phenomenon is peculiar to red cells and is observed only when they are fresh. H. G. R.

**Influence of the plasma on the hæmolysis produced by small variations in  $p_H$ .** R. VAVRA (Compt. rend. Soc. Biol., 1936, 123, 163—165).—When produced in presence of plasma, hæmolysis is probably caused by the plasma itself. H. G. R.

**Influence of trisodium citrate on hæmolysis of red cells by alcohol.** J. VIGNATI and M. RAUCHENBERG (Compt. rend. Soc. Biol., 1936, 123, 165—166).—Hæmolysis is inhibited by EtOH up to 50% concn. H. G. R.

**Production of fibrinolysin *in vivo*.** E. NETER (Proc. Soc. Exp. Biol. Med., 1936, 34, 735—736).—The abdominal washings of mice killed by injection of saline suspensions of various strains of hæmolytic streptococci (but not pneumococci) contained fibrinolysin. P. G. M.

**Decalcifying anticoagulants.** J. H. FERGUSON (Proc. Soc. Exp. Biol. Med., 1936, 34, 797—798).—Incubation of a thrombin solution with 50—100 equivs. of oxalate or citrate for varying times produces both an immediate retardation and a progressive inactivation of clotting. P. G. M.

**Effect of sulphur compounds on blood coagulation.** J. H. STERNER and G. MEDES (Proc. Soc. Exp. Biol. Med., 1936, 34, 597—599).—Addition of cystine to the coagulation system before thrombin formation has a marked inhibitory effect. Inhibition is only slight in the presence of thrombin. Methionine has an inhibitory effect *in vivo* but not *in vitro*. P. G. M.

**Kinetics of thrombin action.** E. WÖHLISCH, W. DIEBOLD, and O. KIDERLEN (Pflüger's Arch., 1935, 237, 599—608).—With increasing fibrinogen (I) concn. up to 0.3—0.4% the rate of clotting increased, but decreased again above his concn.; the max. rate occurred at the blood concn. of (I). The influence of temp. on rate of clotting became progressively less with decreasing concn. of (I) and finally disappeared. M. A. B.

**Blood in hæmophilia.** A. J. PATEK, jun., and F. H. L. TAYLOR (Science, 1936, 84, 271—272).—The difference between normal and hæmophilic blood appears to be due either to a qual. difference of their prothrombins or to other substances probably associated with them. L. S. T.

**Venom of *Lachesis* (*Bothrops*) snakes. IV. Action of the coagulatory principle *in vivo*.** D. VON KLOBUSITZKY and P. KÖNIG (Arch. exp. Path. Pharm., 1936, 182, 577—583; cf. this vol., 1010).—The activity of preps. free from protein, of low toxicity, and effective in doses of  $5 \times 10^{-10}$  g. per c.c. of blood, depends on the time between administration (pigeons) and removal of blood and on concn. F. O. H.

**Rapid process for macroscopic agglutination after centrifuging.** R. LE GUYON (Compt. rend. Soc. Biol., 1936, 123, 239—240).—After centrifuging the mixture of serum and bacterial emulsion, the clot is redispersed by shaking, when agglutination can be observed. H. G. R.

**Relation between complement and prothrombin.** A. J. QUICK (J. Immunol., 1935, 29, 87—97).—A close relation in respect of chemical and physiological properties is indicated. Complement and prothrombin are not identical. CH. ABS. (p)

**General properties of vegetable agglutinins and precipitins.** T. FRÉMONT (Compt. rend. Soc. Biol., 1936, 123, 417—418).—Sp. agglutinins are more readily detected in infected plants than precipitins. H. G. R.

**Distribution of precipitin in serum-globulins of different species.** B. F. CHOW (Proc. Soc. Exp. Biol. Med., 34, 651—653).—The antibody in the pseudoglobulin (I) of antipneumococcus horse serum (sol. at  $p_H$  5.5) is completely pptd. at 7.6; no such pptn. occurs in rabbit (I), the main portion of the antibody being conc. in the euglobulin fraction. P. G. M.

**Albuminous precipitins.** M. BORNAND (Mitt. Lebensm. Hyg., 1936, 27, 24—26).—Precipitin reactions given by antiserum, prepared by immunisation of a rabbit with the muscle-albumin of a chamois or cow, with albuminous substances extracted from the blood or flesh of various animals are described. J. G.

**Distribution of antibody to crystalline ovalbumin in rabbit serum.** M. E. ADAIR and G. L. TAYLOR (J. Hyg., 1936, 36, 564—569).—Pooled antisera from rabbits injected with ovalbumin were fractionated with  $(NH_4)_2SO_4$  to investigate the distribution of the antibody (I) in the serum-proteins. Albumin contained no (I), but all the globulin fractions contained (I) at a fairly uniform concn. W. L. D.

**Specificity of the complement fixation test for amoebiasis.** E. WEISS and L. ARNOLD (Amer. J. Digest. Dis. Nutrition, 1934, 1, 548—552).—EtOH and COMe<sub>2</sub> extracts of *E. histolytica* yield a sp. antigen, by injection of which a sp. antiamoebic serum can be produced. Ox heart lipin antigens used in the Wassermann and the Kahn tests give non-sp. reactions with serum from amoebic dysentery patients and that from various protozoa. The lipins produce antisera containing non-sp. antibodies.

CH. ABS. (p)

**Union with complement as a surface reaction.** II. Changes of surface activity of serum after heat-inactivation of complement function. III. Cause of the dependence of the amount of protein for union on the degree of sensitisation of antigen cells. F. SEELICH (Biochem. Z., 1936, 287, 1—8, 9—17; cf. this vol., 1335).—II. A series of curves shows the  $\sigma$  of fresh and heat-inactivated guinea-pig's serum, both undiluted and at varying dilutions with 0.9% NaCl, against paraffin oil as measured by du Noüy's interfacial tensiometer. The  $\sigma$  of fresh serum is always about 30% < that of inactivated serum, the surface activity greatly increasing during inactivation. At greater dilutions the  $\sigma$ -time curves of normal and heat-treated serum tend to cross. The cause of this increase in surface-active material is discussed.

III. The changes occurring when antigen cells unite with sp. antibody in which the amount of complement protein bound is greater the greater is the degree of sensitisation, are explained in terms of an increase in  $\sigma$  at the absorbing surface,  $\sigma$  progressively increasing with increasing sensitisation.

**Ultrafiltration of type I antipneumococcal sera.** K. GOODNER, F. L. HORSFALL, jun., and J. H. BAUER (Proc. Soc. Exp. Biol. Med., 1936, 34, 617—619).—The smallest sp. antibody of antipneumococcal rabbit serum corresponds with a pore-size of 11 m $\mu$  and of horse serum to 44 m $\mu$ ; the mass of the latter is 64 times that of the former. The antibody of conc. horse serum requires a pore-size of 176 m $\mu$ .

P. G. M.

**New preparation of type-specific polysaccharide from pneumococcus, type I.** B. F. CHOW (Proc. Soc. Exp. Biol. Med., 1936, 34, 667—669).—By a method of prep. minimising hydrolysis, a polysaccharide (I) was obtained which reacted with homologous immune-rabbit serum, previously absorbed with the acetylpolysaccharide (II), but not *vice versa*. (I) produced active immunity in mice, and may be the precursor of (II).

P. G. M.

**Precipitation of diphtheria antoxin by alum.** F. FARAGÓ (Magyar orvosi Arch., 1935, 36, 176—182; Chem. Zentr., 1936, i, 366).—Conditions for obtaining the best prep. are examined.

A. G. P.

**Urea as solvent for antigen extracts.** E. M. MACKEY and R. W. LAMSON (Proc. Soc. Exp. Biol. Med., 1936, 34, 123—125).—Conc. aq. solutions of urea are suitable solvents for antigens which are only slightly or not at all changed on dissolution.

W. McC.

**Antigenic properties of proteins linked through ureide or azo-groups to aromatic nuclei.** W. MUTSAARS and P. E. GREGOIRE (Compt. rend. Soc. Biol., 1936, 123, 144—148). H. G. R.

**Histochemical detection of mineral constituents of tissues.** L. LISON (Bull. Acad. roy. Belg., 1936, [v], 22, 951—967).—An account of difficulties in determining the distribution of Cl and K in animal tissues by histochemical methods. Cl, which exists only in the diffusible form, cannot be accurately demonstrated; non-diffusible K can be shown if the tissue is previously fixed.

J. L. D.

**Determination of small amounts of iodine in organs, particularly in ox thyroid.** W. RUFF (Biochem. Z., 1936, 287, 40—49).—A modification of the Fellenberg method, designed to prevent loss of I on ashing, is described. Right and left sides of the thyroid and the glands of male and female animals have the same I content. The I content varies considerably with the time of the year, having the highest vals. in winter and the lowest in summer. Glands of animals living on the coast are richer in I than those of animals from inland. The thyroxine contents of the glands are independent of the total I content. The pituitary of female animals contains more I than that of male animals and the anterior lobes are richer in I than the posterior.

P. W. C.

**Fractional iodine determinations in human organs. Biological function of tissue-iodine.** A. STURM and L. ROCKMANN (Biochem. Z., 1936, 287, 50—60).—Tables summarise the I contents of human liver, spleen, skeletal and heart muscle, and lung after fractionation with H<sub>2</sub>O and COMe<sub>2</sub>. The total [I], particularly the sol. protein- (thyrogenic) I (I) is decreased in cases of decreased cellular activity (aged people, liver cirrhosis, necrotic liver and lung carcinomatous tissue, tubercular lung tissue). Tissues in cases of abnormally increased metabolic activity are richer in I, particularly in (I). The functional condition of the central nervous system appears to control the distribution of I, particularly of (I), in the organs. The H<sub>2</sub>O-insol. I fraction increases in age and in necrotic tumour tissue at the expense of the (I) fraction.

P. W. C.

(A) Sodium contents, (B) chloride contents, of aqueous and vitreous humour and serum. P. W. SALIT (Amer. J. Ophthalmol., 1934, 17, 706—708, 818—819).—(A) Age has little effect on the Na content of aq. or vitreous humour. Vals. for serum were > those for humour and those for calves > those of adult cattle.

(B) The Cl' contents of aq. and vitreous humour were similar and > that of serum. Vals. were the same for calves and adult oxen.

CH. ABS. (p)

**Analysis of tissues for metallic content.** H. RAMAGE (Nature, 1936, 138, 762—763).—Before spectrographic determination, tissues must first be extracted. After 18 to 24 hr. at room temp., N-HCl extracts from sheep's liver, spleen, and heart the alkalis, Mg, Zn, Mn, Ni, etc., with only a little org. matter: Ca, Cu, and Fe are only partly extracted. Healthy liver contains more Zn than is commonly realised.

L. S. T.

**Copper in the liver of the calf embryo.** Z. GRUZEWSKA and G. ROUSSEL (Compt. rend. Soc. Biol., 1936, 123, 377—379).—The liver of the embryo contains 20—40 times as much Cu as the foetal spleen, and it appears to be in complex combination since it is not liberated by prolonged dialysis. Cu in rabbit liver is very variable. H. G. R.

**Silica content of lungs of infants and of placental tissue.** W. D. McNALLY and W. L. BERGMAN (J. Ind. Hyg., 1935, 17, 171—173).—SiO<sub>2</sub> contents determined were, infants to 3 years 0.34 placenta 0.294, blood 0.13, placental blood 0.32, umbilical cord 0.33 mg. per g. of dried tissue.

CH. ABS. (p)

**Carbonate content of inorganic bone material and its synthesis.** R. KLEMENT (Ber., 1936, 69, [B], 2232—2238).—The content of inorg. bone material does not correspond with an equilibrium between the hydroxyapatite (I) contained therein and the CO<sub>3</sub>'' of the serum. Probably CaCO<sub>3</sub> is carried down by induced pptn. during the formation of (I). The artificial prep. of a product closely resembling natural bone material is described.

H. W.

**Inorganic structure of teeth.** W. F. BALE, M. L. LEFEVRE, and H. C. HODGE (Naturwiss., 1936, 24, 636—637).—Changes in the X-ray diagram of dentine on heating to 900° agree with the view of Klement *et al.* (A., 1933, 296) that the principal constituent is a hydroxyapatite (I), with included or adsorbed carbonates. The X-ray diffraction diagram of commercial Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> changes on heating to 900°, like that of (I), to the diagram of β-Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>. Samples of tooth-substance gave, after the above heating, few diagrams showing a similar change, but after 5 hr. heating of dentine from certain teeth, the diagram of β-Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> was obtained in many cases. Powdered dentine after extraction for 1½ hr. with (CH<sub>2</sub>·OH)<sub>2</sub> and 3% KOH showed no such transformation. The differences observable in the tooth-substance of different teeth can be ascribed to the extent of adsorption of PO<sub>4</sub>''' on the surface of the small (I) crystals. A. J. M.

**X-Ray absorption coefficients of coronal and root dentine.** F. HOLLANDER and E. VESELY (Proc. Soc. Exp. Biol. Med., 1936, 34, 158—159).—The coeffs. were different in different parts of the dentine of the same specimen and there were differences of >20% between different specimens. In any one specimen there is a uniform decrease in the coeff. from crown to apex of the root, the gradient being parallel to the age gradient of the dentine. W. McC.

**X-Ray diffraction patterns from reprecipitated connective tissue.** R. W. G. WYCKOFF and R. B. COREY (Proc. Soc. Exp. Biol. Med., 1936, 34, 285—287).—The part of the freshly excised tendon of the tail of the adult rat which dissolves in dil. AcOH and is repptd. by 5% aq. NaCl is cryst. and has the same X-ray diffraction pattern as has the original tendon. W. McC.

**Mechanism of hexose monophosphate formation in muscle and isolation of a new phosphate ester.** C. F. CORI and G. T. CORI (Proc. Soc. Exp.

Biol. Med., 1936, 34, 702—705).—Glucose-1-phosphoric acid was isolated as the brucine salt from minced frog muscle incubated with adenylic acid in phosphate buffer. It is readily converted into hexose monophosphate.

P. G. M.

**Comparative biochemistry of muscle. I. Phosphagen in sea- and fresh-water Teleostei and Ganoidei.** L. E. ROZENFELD and G. J. BAGDASARJANTZ. II. Nature of phosphagen in the Selachii. G. J. BAGDASARJANTZ (Ukrain. Biochem. J., 1936, 9, 321—332, 333—340).—I. The skeletal muscles of *Acanthopterygii* and *Lophobranchii* contain 0.007—0.015% of creatinephosphoric acid (I). The P of (I) amounts to 3—8% of the inorg. and acid-labile P, significantly < that in the lower vertebrates. The creatine content of muscle of salt-water fish is < that of fresh-water fish. Sturgeon muscle does not differ from that of bony fish in creatine or (I) content.

II. Muscle of the shark and ray contains 0.013—0.035% of (I). An acid-labile P compound, probably argininephosphoric acid (II), is also present. The total amount of (I) and (II) in the shark is > that in the ray.

F. A. A.

**Biochemistry of carbohydrates. XIV. Modified Zuckerkandl-Klebermass method for determination of glucosamine.** Distribution of glucosaminase in ox tissue. XV. Determination of N-acetylglucosamine and its application to biochemical analysis. K. WATANABE (J. Biochem. Japan, 1936, 23, 365—369, 371—376; cf. A., 1935, 402).—XIV. The method (A., 1931, 1081) indicates that glucosaminase occurs in liver, lung, pancreas, and kidney but not significantly in spleen, thyroid gland, muscle, and adrenal cortex.

XV. The above method is applicable to the determination of N-acetylglucosamine in tissue, blood, or urine.

F. O. H.

**Glycogen content of fresh-water mussels during prolonged starvation.** M. M. ELLIS and D. B. CALVIN (Proc. Soc. Exp. Biol. Med., 1936, 34, 222—225).—The dried hepatopancreas and pedal muscle of several species of thick-shelled mussel contained 25—61% of glycogen (I). The (I) content decreased slowly during starvation; in many cases it remained >30% after 180—338 days. After 536 days the average (I) content of one species was 1.1%. The (I) content of thin-shelled was < that of thick-shelled mussels and decreased more rapidly during starvation.

W. McC.

**Chemical and histochemical determination of the glycogen contents of white and red muscle.** A. NOLL and M. BECKER (Biochem. Z., 1936, 287, 88—91).—In rabbits and hens, red muscle contains 66—80% of the amount of glycogen (I) of white muscle. Histochemical determination gave in general a lower (I) content for red muscle, the vals., especially with rabbit's muscle, agreeing closely with those by chemical methods. In hens, the red muscle of the legs must be used whole in chemical determinations, since (I) is not evenly distributed therein.

P. W. C.

**Fats of Japanese birds. XVII. Fat from *Oreocincla dauma*, Holandre [White's ground**

thrush]. R. KOYAMA (J. Chem. Soc. Japan, 1935, 56, 596—599).—Data are recorded. CH. ABS. (e)

Oil extracted by pressure from the male silk-worm butterfly. M. BONICATTI (Annali Chim. Appl., 1936, 26, 306—309).—The oil, obtained in 20% yield, has I val. 110—116, acid val. 22—38, solid fatty acids 27.1—33.2%; it differs little from the chrysalis oil. L. A. O'N.

Inversion point of cholesterol in aqueous suspension by calcium chloride. H. G. B. DE JONG and N. I. JOUKOVSKY (Compt. rend. Soc. Biol., 1936, 123, 154—156).—The  $[\text{CaCl}_2]$  corresponding with the inversion of cholesterol is 2.8N. H. G. R.

Chemical composition of various divisions of the nervous system. A. V. PALLADIN, E. J. RASCHBA, and R. M. GELMAN (Ukrain. Biochem. J., 1936, 9, 169—192).—In the peripheral nervous system of cows, the roots of the spinal cord contain a relatively large amount of cholesterol (I) (17—18% of the dry matter). The anterior and posterior roots are similar to each other in composition, per unit of dry matter. Lipins, N, creatine, P, and  $\text{H}_2\text{O}$  are lower in the peripheral nerve than in the other divisions (possibly owing to a high fat content), whilst the sympathetic trunk is relatively rich in N and creatine. The ganglia of the posterior roots differ from other ganglia in having high (I) and unsaturated phosphatide content. Phylogenetically, the peripheral nervous system resembles the central nervous system in that the older divisions are rich in (I) and unsaturated phosphatides, while the younger divisions are richer in  $\text{H}_2\text{O}$  and proteins. F. A. A.

Chemistry of vitreous humour. III. Lipins. A. C. KRAUSE (Arch. Ophthalmol., 1935, 13, 1022—1025; cf. A., 1935, 511).—In bovine humour parts of the lipin and cholesterol (I) contents are bound to protein. No cholesteryl fatty acid esters are present. Particles of (I) and Ca soaps in the humour probably arise from liberation of lipins of leucocytes. CH. ABS. (p)

Biochemistry of the lens. IV. Origin of pigment. J. G. BELLOW (Arch. Ophthalmol., 1935, 14, 99—107).—The lens contains histone and protamine. The latter reacts with cysteine (I) to form a black dye. A normal hydrolysed lens becomes pigmented when placed in a slightly alkaline solution of (I). CH. ABS. (p)

Cellular hæmatins and cytochromes. J. ROCHE and M. T. BENEVENT (Compt. rend. Soc. Biol., 1936, 123, 20—22; cf. this vol., 1287).—The hæmatins (I) of cytochrome-A and -A<sub>2</sub> are similar if not identical, whilst those of -A<sub>3</sub> are very different, the hæmochromogens absorbing in the orange-red. Pigments B, B<sub>1</sub>, and C and Keilin's intracellular (I) yield, with  $\text{C}_5\text{H}_5\text{N}$ , a mixture of (I)-C and proto-hæmatin in varying proportions. H. G. R.

Hæmatin- and cytochrome-C. Mobility of iron and combinations of hæmatins with a globin. J. ROCHE and M. T. BENEVENT (Compt. rend. Soc. Biol., 1936, 123, 18—19).—The absorption spectra of the products of condensation of proto-hæmatin with  $\text{C}_5\text{H}_5\text{N}$  and with  $\text{NH}_2\text{CH}_2\text{CO}_2\text{Me}$  are identical. Hæmatin-C (I), obtained from the proto-

hæmatin by alternate oxidation and reduction, will not combine with horse globin and when boiled in MeOH with 1% HCl yields a porphyrin and  $\text{Fe}^{+++}$ , in contrast to Zeile's (I), that of cytochrome-C, and of blood. H. G. R.

Chemical studies on bioluminescence. III. Reversible reaction of *Cypridina* luciferin with oxidising agents and its relations to the luminescent reaction. R. S. ANDERSON (J. Cell. Comp. Physiol., 1936, 8, 261—276; cf. this vol., 360).—Oxidation of luciferin (I) by  $\text{K}_3\text{Fe}(\text{CN})_6$ , unlike that by  $\text{O}_2$  in the presence of luciferase, is reversible, as (I) is re-formed largely in the former, but only to a slight extent in the latter, case on addition of  $\text{Na}_2\text{S}_2\text{O}_4$ . The end products of the two reactions are therefore different. Abnormal reaction curves obtained may be due to mixtures of (I) and reversibly oxidised (I). A preliminary val. for the apparent oxidation-reduction potential of the (I) system is given. Possible chemical characteristics of (I) are discussed. E. A. H. R.

Influence of starvation on the content of plant-auxin-like substances in the larva of *Disco-glossus pictus*, Otth. H. BERRIER (Compt. rend., 1936, 203, 522—524; cf. A., 1935, 1289).—The auxin-like activity of *D. pictus* persists during the normal larval stage but disappears on starving the larvæ for 15 days. F. O. H.

Nettle poisons. Poison of sea anemones. I. R. SONDERHOFF (Annalen, 1936, 525, 138—150).—*Anemonia sulcata* yields to EtOH a highly active substance, containing C, H, O, N, and S, having a mol. wt. about 2000 (determined by dialysis), and probably of albumin (histone) type. The isolation, physiological properties, method of testing (*Rana esculenta*, not *temporaria*), and colour reactions are detailed. R. S. C.

Isolation of the anti-anæmic principle of the liver. P. LALAND, A. KLEM, B. STRANDELL, L. POULSSON, and H. SCHARTUM-HANSEN (Acta med. scand., 1936, 88, 620—623, 624—625).—The method of isolation depends on extraction with PhOH which removes much of the inactive substances. Several fractions isolated by variations of this method had an anti-anæmic effect. A fraction isolated by a combination of the  $(\text{NH}_4)_2\text{SO}_4$  process of Dakin and West and the PhOH extraction method gave 0.35 mg. of dry material per 100 g. of liver. 0.7 mg. of this material produced an excellent response in four cases of pernicious anæmia. NUTR. ABS. (m)

Physical and chemical properties of desiccated stomach. J. KYER, F. P. BROOKS, and R. ISAACS (Proc. Soc. Exp. Biol. Med., 1936, 34, 677—680).—A  $\text{H}_2\text{O}$  extract of desiccated hog's stomach ( $p_{\text{H}}$  4.5) is effective in treatment of pernicious anæmia. The active principle is alkali-stable and is not ultra-filterable; it contains two factors, one heat-stable and the other heat-labile. Incubation of an acid extract yields a hæmatopoietic substance sol. in 70% EtOH. P. G. M.

Heparin. IV. Chemistry of heparin. A. F. CHARLES and D. A. SCOTT (Biochem. J., 1936, 30, 1927—1933).—A very active prep. of heparin (I) is

obtained from ox lung (cf. A., 1935, 632). Analyses of the Ba and benzidine salts indicate the empirical formula  $C_{25}H_{65}O_{50}N_2S_5$  for (I). The S is present as  $\cdot SO_3H$  and is removed by  $MeOH-HCl$  as  $SO_4^{2-}$  with loss of activity. Part of the N is present as  $\cdot NH_2$  groups and these are associated with the physiological activity. Colour tests indicate the presence of a carbohydrate complex and the absence of pentoses and glycuronic acid. The cryst. prep. is 22 times as active as the commercial product. Analyses do not support the view that (I) is a chondroitinpolysulphuric acid.

P. W. C.

**Progestin content of human placenta.** D. A. MCGINTY, N. B. MCCULLOUGH, and J. G. WOLTER (Proc. Soc. Exp. Biol. Med., 1936, 34, 176—178).—Fresh full-term human placenta contains approx. 7 rabbit units of progestin per kg.

W. McC.

**Organic bases, especially spermine, in the muscle of higher animals.** II. K. YOSHIMURA, Y. HIWATASHI, and T. SAKOMOTO (J. Chem. Soc. Japan, 1935, 56, 582—587).—Freshly ground muscle of rabbit and of wild boar contains creatine 10.8, 0.30, hypoxanthine hydrochloride 0.6, 2.05, methylguanidine 1.2, 0.30, creatinine 1.7, 2.05, carnitine 1.8, 6.0, and spermine 0.0, 0.0 g. per 5 kg., respectively.

CH. ABS. (p)

**Brain-creatine during the ontogenetic development of vertebrates.** A. PALLADIN and H. RASCHBA (Ukrain. Biochem. J., 1936, 9, No. 1, 5—42).—In various mammals the creatine and total N content of the brain decreases during development. In chicks a less marked fall takes place.

W. O. K.

**Creatine content of human hearts.** G. HERRMANN, G. M. DECHERD, jun., and T. OLIVER (Proc. Soc. Exp. Biol. Med., 1936, 34, 827—829).—The creatine content of hearts from patients who died of infectious disease is lowered, as is that of hearts showing myocardial change consequent on coronary sclerosis; in hypertrophied hearts the content is raised if they have not failed, and *vice versa*.

P. G. M.

**Tissue-acetylcholine. IV. Cytology of chorionic villous epithelium of the human placenta.** I. C. WEN, H. C. CHANG, and A. WONG (Chinese J. Physiol., 1936, 10, 559—569).—Fixation with  $NH_4$  reineckate preps. is used to indicate the liberation of choline granules in various histological elements of placental tissue, the results being correlated with the acetylcholine activity of different types of placenta.

P. W. C.

**Structure of proteins and of certain physiologically active compounds.** D. M. WRINCH (Nature, 1936, 138, 651—652).—The cyclol theory of protein structure and the part played by the cyclol pattern in the structure of carcinogenic substances is discussed.

L. S. T.

**Digestion products formed by the action of papain on ovalbumin.** M. ANNETTS (Biochem. J., 1936, 30, 1807—1814).—Under the action of papain the ovalbumin (I) mol. is split up into two groups of substances, both heterogeneous, a light fraction consisting of particles of the order of magnitude of the  $NH_2$ -acids and lower polypeptides and a heavy fraction containing no unchanged (I) and having an

average sedimentation const. of 3.3 and diffusion const. of 8.27 sq. cm. per sec. Ultracentrifuge,  $n$ , diffusion, cataphoresis, and light absorption measurements all lead to the view that first a change occurs in all the mols. of (I), probably a loosening of bonds within the mol., followed by a gradual splitting off of small pieces from these modified mols.

P. W. C.

**Swelling of the vitreous gel and intraocular pressure.** M. COHEN, J. M. NEWELL, and J. A. KILLIAN (Arch. Ophthalmol., 1934, 12, 352—358).— $H_2O$  and solutions of acids, alkalis, and  $NaCNS$ , separated from the vitreous gel by a porous alundum disc, produced no swelling of the gel. Pressure ultrafiltration through Cellophane removed >99% of protein-free liquid from the gel. The residue swelled when placed in the  $H_2O$ . A true swelling of vitreous gel is impossible.

CH. ABS. (p)

**Protein content of human aqueous [humour].** E. SELINGER (Amer. J. Ophthalmol., 1934, 17, 1130—1137).—A method for determining protein is based on treatment with  $CCl_3CO_2H$  and comparison of turbidity. Vals. for normal and pathological conditions are given.

CH. ABS. (p)

**Inversion point of autocomplex coacervates of phosphatides by calcium chloride as a function of  $p_H$ .** H. G. B. DE JONG and N. I. JOUKOVSKY (Compt. rend. Soc. Biol., 1936, 123, 149—154).—Between  $p_H$  4 and 9 the  $[CaCl_2]$  necessary to cause inversion of the electro-capillary charge is practically const. On the acid side the val. falls rapidly to zero ( $p_H$  1.82) and increases rapidly when alkaline.

H. G. R.

**X-Ray diffraction studies of chitin, chitosan, and derivatives.**—See this vol., 1451.

**Adsorption of benzene derivatives by serum colloids and organ pulps.**—See this vol., 1462.

**Elastoïdin fibres.**—See this vol., 1462.

**Milk of the merino ewe.** A. W. PEIRCE (Austral. J. Exp. Biol., 1936, 14, 187—192).—Colostrum differed from milk principally in its higher proportions of casein, lactalbumin, globulins, and lactose. Seasonal variations in two typical breeds are examined.

A. G. P.

**Copper, zinc, and manganese content of cows' milk.** A. BROEK and L. K. WOLFF (Acta brev. neerl. Physiol., 1935, 5, 80—81; Chem. Zentr., 1936, i, 461).—The Cu content was  $15-50 \times 10^{-6}$  g. per litre, and was uninfluenced by season or diet. The Zn was 1.94—4.96 mg. per litre. Mn averaged  $10^{-6}$  g. per litre; this val. was influenced much more by org. than by inorg. Mn in the feed.

H. J. E.

**Determination of vitamin-C content of fresh milk.** W. LOJANDER (Suomen Kem., 1936, 9, A, 111—114).—Several 20-c.c. samples of milk are treated respectively with increasing amounts of a standard solution of dichlorophenol-indophenol, and after 10 min. in the dark, the -C content corresponds with that amount of indicator between the last white and the first coloured test. The method fails with milk containing many bacteria.

J. N. A.

**Occurrence and possible significance of some minor components of cow-milk fat.** T. P. HIL-

DITCH and H. PAUL (Biochem. J., 1936, 30, 1905—1914).—Results of analyses of the component acids of milk fat are calc. (a) on the assumption that no unsaturated acids of lower mol. wt. than oleic acid (I) are present, and (b) allowing for the presence of decenoic (II), tetra- (III) and hexa-decenoic (IV) acids. Comparison of these results with those for the similar analysis of completely hydrogenated butter indicates the presence of lower unsaturated acids. In addition to traces of (II) and  $\leq 1\%$  of (III), there must be present about 4–5% of (IV). By applying the correction, the palmitic acid val. is increased by 2% and the (I) val. decreased by 5%. There is no detectable amount of any unsaturated acid of lower mol. wt. than  $\Delta^9:10$ -(II) in butter fat. The minor lower unsaturated components are probably degradation products of oleo-glycerides which have escaped complete saturation. P. W. C.

Variation of the fat content of milk with the time of day. Z. CZUKAS (Mezög.-Kutat., 1935, 8, 270—279; Chem. Zentr., 1936, i, 461).—Tests with 8 cows on 94 days showed that morning milk had a 40%, and evening milk a 29%, lower fat content than midday milk. H. J. E.

Hydrogen-ion concentration of tears: relation to certain ocular symptoms and to conjunctival and corneal lesions. G. N. HOSFORD and A. M. HICKS (Arch. Ophthalmol., 1935, 13, 14—25).—Tears are sufficiently buffered to permit sufficient dilution for practicable determinations of  $p_H$ . Vals. for normal eyes averaged 7.35. Protein and salt errors and the relation of tears to certain bacteria are discussed. CH. ABS. (p)

Influence of the nature of the stimulant on the quantity, chloride content, and  $p_H$  of the salivary secretion. E. J. BIENKA and C. SZCZEPANSKI (Compt. rend. Soc. Biol., 1936, 123, 32—34).—The secretion is affected less by mechanical than by chemical stimulation. When stimulation is rapid or the medium alkaline, the Cl' content is  $>$  and the  $p_H <$  that on slow stimulation or in acid medium. H. G. R.

Bile-sugar. G. BALTAČEANO and C. VASILIU (Compt. rend. Soc. Biol., 1936, 123, 54—55).—In bile the free sugar is glucose and the protein-bound sugar lactose. H. G. R.

Method of determining total pigment in bile applicable to "biliverdin" biles. C. R. SCHMIDT, K. K. JONES, and A. C. IVY (Proc. Soc. Exp. Biol. Med., 1936, 34, 17—21).—The bile-pigments are oxidised to yellow compounds by  $(NH_4)_2S_2O_8$  in presence of  $AcOH-EtOH$  (1:1) and then determined colorimetrically. W. O. K.

Determination of cholic acid in bile and in duodenal drainage. H. DOUBILET (Proc. Soc. Exp. Biol. Med., 1936, 34, 84—86).—The Gregory-Pascoe reaction (cf. A., 1929, 1114) is applied to the determination of cholic acid in bile. W. O. K.

Influence of diet on formation of hepatic and renal calculi. IV. Histological study of liver, gall-bladder, and kidneys. V. Changes of hydrogen-ion concentration and the buffer action of the bile. K. USUKI (Japan. J. Gastro-

enterol., 1934, 6, 94—104, 105—111).—V. In young rabbits receiving a diet deficient in fat-sol. vitamins, the liver and gall-bladder biles showed lowered  $p_H$  and buffer action, with which is associated the formation of calculi. CH. ABS. (p)

Quantitative studies of the normal human gastric secretion. S. WANG (Chinese J. Physiol., 1936, 10, 493—506).—The HCl, neutral Cl', and non-Cl' alkaline (base+mucus+pepsin) components of gastric juice of four normal human subjects were investigated, histamine being used as stimulant. The HCl and neutral Cl' were secreted in proportional vols. at const. concn. in the order approximating to the electrolyte concn. of the blood. Both vals. were numerically  $<$  those in dogs. During active secretion, the vol. of the alkaline component is small. The total base and Cl' concn. of the serum is remarkably const. P. W. C.

Gastric secretion during the night. A. WINKELSTEIN (Amer. J. Digest. Dis. Nutrition, 1934, 1, 778—782).—Normal curves of gastric secretion show little HCl during the night. In cases of gastric or intestinal ulcers, secretion and HCl content are high. Nocturnal hyperchlorhydria is not controlled by alkalis, olive oil, atropine, or aspiration. CH. ABS. (p)

Influence of the pylorus on the regulation of the acidity of gastric secretion. W. W. LERMANN and L. M. NELSON, jun. (Amer. J. Digest. Dis. Nutrition, 1934, 1, 245—247).—Regurgitation of bile and trypsin and lowered acidity in the digesting stomach were observed, the pylorus being held open during the test. CH. ABS. (p)

Dry natural digestive juices: properties and use. W. N. BOLDYREFF (Amer. J. Digest. Dis. Nutrition, 1935, 2, 33—36).—The dry residue from vac. evaporation of freshly collected and cooled juice may be preserved without an antiseptic. Technique of prep. is described. CH. ABS. (p)

Relations between hæmoglobin and gastric acidity. W. C. ALVAREZ and F. R. VANZANT (Proc. Staff Meetings Mayo Clin., 1936, 11, 385—391).—There was a marked rise in the incidence of achlorhydria in man as the hæmoglobin (I) vals. fell below 12 g. per 100 ml., and the mean gastric acidity decreased rapidly below this (I) level. With (I) levels  $>18$  g. per 100 ml., mean gastric acidity decreased slightly, and the incidence of achlorhydria was normal. Severe anæmia is not incompatible with the presence of excess of acid, and the presence of great excess of hæmoglobin is compatible with achlorhydria. NUTR. ABS. (m)

Gastro-intestinal studies. V. Gastric juice in anæmias other than pernicious anæmia. P. J. FOUTS, O. M. HELMER, and L. G. ZERTAS (Amer. J. Digest. Dis. Nutrition, 1934, 1, 677—684).—No enzymes were found in gastric juice having  $p_H < 7.0$ . No improvement in gastric secretion was found when the gastric contents, after histamine stimulation, had  $p_H > 7.0$  and contained no enzymes. CH. ABS. (p)

Anti-pernicious anæmia principle in gastric juice. A. W. C. G. KAMERLING and W. GROTEPASS

(Nederland. Tijds. Geneesk., 1936, 80, II, 1991).—The effect of liver is increased by incubation with normal gastric juice, but not with the gastric juice of pernicious anaemia patients. Pepsin-HCl digestion does not increase the activity of liver. After removal of the enzymes of gastric juice the ultrafiltrate from active liver digests was equally active, even after heating at 80° for 30 min. NUTR. ABS. (m)

**Buffer capacity of pancreatic juice.** M. T. HOERNER (Amer. J. Digest. Dis. Nutrition, 1935, 2, 300—302).—Protein diets induced a greater flow of secretion than did other test meals. The buffer capacity of the juice reached max. 1—3 hr. after ingestion of food and gradually diminished as the acidity of the duodenum declined. The secretion was always alkaline and possessed slight buffer capacity even during fasting. CH. ABS. (p)

**Effect of exclusion of pancreatic secretion by evulsion of the pancreatic ducts on reaction of duodenal contents.** M. T. HOERNER (Amer. J. Digest. Dis. Nutrition, 1935, 2, 295—297).—The  $p_H$  of the contents during fasting was 7.00—7.81, after a meat meal 6.40—3.50, after a carbohydrate meal 6.75—4.26, and after a fat meal 6.80—5.20. In the absence of pancreatic juice the total buffer secretions are smaller but the bile and succus entericus maintain a normal  $p_H$  except when gastric matter of high acidity enters the duodenum. CH. ABS. (p)

**Effect of exclusion of pancreatic secretion by a pancreatic fistula on reaction of gastric, duodenal, and jejunal contents.** M. T. HOERNER (Amer. J. Digest. Dis. Nutrition, 1935, 2, 298—300).—Production of a pancreatic fistula caused no change in the  $p_H$  of gastric contents during fasting or after test meals. The  $p_H$  of duodenal contents was normal during fasting, but protein and carbohydrate meals caused a more rapid and prolonged decline in  $p_H$  than when pancreatic secretion was present. Similar changes occurred in the jejunal contents, but only after a protein diet. CH. ABS. (p)

**Reaction of the contents of the isolated duodenum.** P. R. LINES (Amer. J. Digest. Dis. Nutrition, 1935, 2, 285—288).—The alkalinity of the contents ( $p_H$  7.10—8.15) is caused by weak alkalis or buffer substances, fluctuations in which depend on the relative proportions of pancreatic juice, bile, and duodenal secretion present. The alkalinity of pancreatic juice is approx. double that of bile. CH. ABS. (p)

**Capacity of duodenum to neutralise, to buffer, and to dilute acid.** G. A. STEVENS (Amer. J. Digest. Dis. Nutrition, 1935, 2, 288—293).—The increase in neutralising capacity after a fat meal and the decrease after a protein meal are attributed to inhibition and stimulation, respectively, of the gastric juice. HCl introduced continuously in small amounts is neutralised, buffered, and diluted; little is absorbed in the duodenum. A large single injection of acid is swept through the duodenum by peristalsis. CH. ABS. (p)

**Reaction of duodenal content after exclusion of bile from duodenum.** J. W. McROBERTS (Amer. J. Digest. Dis. Nutrition, 1935, 2, 293—294).—Loss

of bile did not materially affect the  $p_H$  of duodenal contents in dogs. CH. ABS. (p)

**Determination of ketones in urine.** J. TROTZKI and R. MENDELSON (Ukrain. Biochem. J., 1936, 9, No. 1, 157—163).—The urine is treated first with  $Pb(OAc)_2$  and aq.  $NH_3$  and then with  $Pb(OAc)_2$  and NaOH. The  $COMe_2$  in a portion of the filtrate acidified with AcOH is distilled into aq. NaOI,  $K_2Cr_2O_7$  and  $H_2SO_4$  being added to the distillation flask at intervals. W. O. K.

**Detection of pyruvic acid in urine.** A. PISUNER and M. FARRAN (Biochem. Z., 1936, 287, 113—114; 288, 294).— $AcCO_2H$  is isolated as the dinitrophenylhydrazone, m.p. 216°. P. W. C.

**Methylmalonic acid from rat urine.** E. BOYLAND and A. A. LEVI (Biochem. J., 1936, 30, 2007—2008; cf. this vol., 234).—Methylmalonic acid (I) was isolated in yields  $>0.5$  g. per litre from rats' urine, but could not be found in human and rabbits' urine. (I) separates from  $H_2O$  as monohydrate. Thymine is a possible precursor of (I) in the organism. The Na salt of (I) does not inhibit respiration and acetoacetate breakdown in liver slices. W. McC.

**Origin of trimethylamine in human and animal urine.** S. V. FOMIN (Ukrain. Biochem. J., 1936, 9, No. 1, 143—155).— $NMe_3$  in human or pig urine is of exogenous origin. W. O. K.

**Phenols or glyoxalines in urine.** A. D. MARENZI and R. F. BANFI (Compt. rend. Soc. Biol., 1936, 123, 73—74).—The diazo-reaction of urine is principally due to phenols. H. G. R.

**Excretion of ammonia and uric acid by larvæ of muscoid flies.** A. W. A. BROWN (J. Exp. Biol., 1936, 13, 131—139).—Small amounts of uric acid (I) were found in tissues and excreta of *Calliphora erythrocephala*, *Mg.*, and *Wohlfahrtia vigil*, *Wlk.*  $NH_3$  excretion increased with rise in body-wt. of *Calliphora* larvæ, but there was a lag of 1 day in *Wohlfahrtia*. (I) excretion increased in a similar manner but the amount was very much less. In *Calliphora* a diet of caseinogen proved adequate and ovalbumin inadequate. The caseinogen diet brought about an excretion of  $NH_3$  and (I) about twice as great as that on a normal meat diet. NUTR. ABS. (m)

**Determination of veronal [in urine].** G. SACK (Arch. exp. Path. Pharm., 1936, 183, 71—76).—Urine (10—20 c.c.) is treated with  $Pb(OAc)_2$ -AcOH and filtered and the material extracted from the filtrate by  $Et_2O$  is purified by treatment with  $K_2Cr_2O_7$ - $H_2SO_4$  followed by  $H_2O_2$  and freed from fat by successive treatments with  $EtOH$  and  $H_2O$ . The final  $Et_2O$  extract of the aq. solution is evaporated to dryness and weighed. The accuracy is  $\pm 5\%$ . A qual. test is given. F. O. H.

**Colour reaction for the urine of pregnancy.** P. E. SMOLA (Suomen Kem., 1936, 9, B, 20).—I is added, the solution boiled, and shaken with amyl alcohol. The alcohol layer assumes a red-violet colour in 70% of the cases examined. A. L.

**Losses of nitrogen and carbon in drying the faeces of cattle.** M. KLEIBER, R. W. CALDWELL, and H. JOHNSON (Proc. Soc. Exp. Biol. Med., 1936,

34, 128—130).—N determinations in faeces should be made with fresh samples immediately after defecation since storage and drying result in N losses of  $4.48-7.19 \pm 0.049\%$ . C is best determined by combustion of dried faeces in  $O_2$  at 25 atm. The loss of C on drying ( $1.36 \pm 0.08\%$ ) is determined in a special apparatus. 35—55% of the lost C occurs as pre-formed  $CO_2$ . W. McC.

**Elimination by sweat in an ozonised atmosphere.** THIODET and RIBERE (Compt. rend. Soc. Biol., 1936, 123, 329—330).—An analysis of the sweat is given, an increase in the elimination of toxic substances being apparent. H. G. R.

**Pathogenesis of oil acne.** N. S. VEDROV and A. P. DOLGOV (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 428—436).—Compounds of the type of naphthene, in naphtha oil, can cause skin affections of the type of oil acne. Purification of the oil does not render it completely harmless. Sulphonated and unsulphonated oils have the same effect. M. A. B.

**Serum electrolytes and mineral metabolism in a case of Addison's disease. Use of adrenal cortical extract (Eschatin).** S. K. CHOU, K. C. CHEN, S. H. LIU, and S. S. FANG (Chinese Med. J., 1936, 50, 1013—1024).—A case is reported of Addison's disease accompanied by pulmonary tuberculosis. Low plasma vol., low total base, serum-Na and -Cl vals. were found, which were temporarily relieved by Eschatin. Later doses were ineffective, owing to mineral loss by tissue destruction as a result of active pulmonary tuberculosis. G. H. B.

**Anæmia caused by deaminised caseinogen.** A. G. HOGAN, R. E. GUERRANT, and W. S. RITCHIE (J. Biol. Chem., 1936, 115, 659—672; cf. A., 1934, 1387).—For a given diet, a ration of approx. 5% of caseinogen (I) prevents, whilst a min. of 5—10% of deaminised (I) produces, an anæmia in rats which is not alleviated by milk, egg yolk, wheat germ oil, muscle, or liver or stomach preps. Laboratory preps. of lactalbumin do not prevent the anæmia and those of ovalbumin have a variable effect; commercial preps. of both proteins, however, prevent anæmia, as does dried yeast (aq. extracts of which are inactive). Autoclaved (I) or yeast has no curative action. The anæmia and anti-anæmia factors occur in the 25%  $H_2SO_4$  hydrolysate of deaminised and normal (I), respectively. F. O. H.

**Origin of the anti-anæmic factor. IX. Action of the liver in pernicious anæmia.** F. REIMANN, H. BIEDERMANN, and L. ZWILLIGER (Z. Klin. Med., 1935, 128, 205—212; Chem. Zentr., 1936, i, 585).

**Basal metabolism in experimental anæmias.** K. C. CHEN and H. C. CHANG (Proc. Soc. Exp. Biol. Med., 1936, 34, 646—648).—In  $NH_4Ph$  anæmia there is only a fleeting increase in basal metabolic rate, and the immature blood cells contribute little to the total  $O_2$  consumption. There is no strict relation between  $O_2$  consumption and reticulocyte count. P. G. M.

**Myohæmoglobin content of the hypertrophied heart of the anæmic rat.** D. W. COWAN and L. C. BAUGUESS (Proc. Soc. Exp. Biol. Med., 1936, 34, 636—637).—In spite of severe anæmia rats are able to

maintain normal muscle-hæmoglobin concn. during development of abnormal hypertrophy. P. G. M.

**Changes in the protein equilibrium of blood during asthma.** AUBRY, THIODET, and RIBERE (Compt. rend. Soc. Biol., 1936, 123, 327—328).—During an attack the albumin:globulin ratio and the albumin content decrease and the globulin content increases. H. G. R.

**Chemistry of carcinoma. II.** A. VON CHRISTIAN (Z. Krebsforsch., 1935, 42, 25—29; Chem. Zentr., 1936, i, 360).—Cytolysis of carcinoma by serum is inhibited by cholesteryl *n*-butyrate, isovalerate, and palmitate. A. G. P.

**Glycolysis in cancer. II.** C. FRISCH and R. WILLHEIM (Biochem. Z., 1936, 287, 198—202; cf. A., 1935, 885).—The inhibition of glycolysis in muscle extract by benzoquinone is not counteracted by extracts of healthy kidney, spleen, muscle, embryonal tissue (hen), or by ascorbic acid and hence the counter-acting effect of tumour extract is sp. W. McC.

(A) Lysine as a factor in malignant growth. C. VOEGTLIN and J. W. THOMPSON. (B) Effect of gliadin diet on malignant growth. C. VOEGTLIN and M. E. MAVER (U.S. Publ. Health Repts., 1936, 51, 1429—1436, 1436—1444).—(A) A diet of 70% wheat meal and 30% whole milk powder gives normal growth in rats and rapid growth of mammary carcinoma in mice. Heating the milk powder renders it inadequate for normal and inhibitory to malignant growth. Administration of lysine removes the inhibition of normal and malignant growth and an adequate supply is necessary for rapid growth of malignant tumour.

(B) Normal growth of young mice and growth of spontaneous mammary carcinoma in adult mice are inhibited by diets containing gliadin (I) as the only protein source, but the addition of lysine makes the diet adequate for both forms of growth. The effect of glutenin (II) is different from that of (I) in that growth is not inhibited. (II) is a complete protein and (I) is deficient in lysine. Lysine is necessary for the growth of mammary carcinoma. W. L. D.

**Diagnosis of cancer.** P. MENDELEEFF (Compt. rend. Soc. Biol., 1936, 123, 135—137).—The pituitary in cancer secretes a substance detectable in the blood, cerebrospinal fluid, saliva, and urine by the coagulating action on plasma *in vitro*. H. G. R.

**Calcium and protein of blood and blister fluid in malignant disease.** R. O. BOWMAN, H. C. PITTS, P. H. MITCHELL, and E. EWERTZ (Canad. Med. Assoc. J., 1936, 34, 527—532).—K, P, Ca, and total protein were determined in the blood-serum and fluid from artificially raised blisters of 50 cancerous and 22 non-cancerous subjects. Since the average Ca of the fluid in the cancerous was < in the non-cancerous group malignancy may be related to a Ca deficiency not evident in the blood-serum but appearing in the blister fluid. Corresponding differences were noted in respect of P and (especially) protein, which was significantly lower in the blood and fluid of cancerous individuals. NUTR. ABS. (m)

**Total sulphur of tissue in normal and abnormal growth (mouse carcinoma).** H. BROWN and J. V. KLAUDER (J. Lab. Clin. Med., 1935, 20, 1143—

1150).—The S content of the skin of rabbits decreases with the falling rate of growth from birth to maturity. After maintenance on a low-cystine diet the S content of normal organs of mice declines, and the no. of infections and rate of growth of inoculated tumours are reduced. Rapidly growing tumours contain more S than slow-growing ones. CH. ABS. (p)

**Paraffin and mineral oil cancer.** WELWART (Seifensieder-Ztg., 1935, 62, 792—793; Chem. Zentr., 1936, i, 360).—The carcinogenic action of mineral oils is associated with the unsaturated hydrocarbons, notably 1:2:5:6-dibenzanthracene and 1:2-benzpyrene, and textile spinning oils. A. G. P.

**Prophylaxis of benzpyrene cancer with organic peroxides.** J. MAISIN and F. ROBERT (Compt. rend. Soc. Biol. 1936, 123, 156—159).—Diformaldehyde peroxide (A., 1935, 1526) and  $\text{HCO}_3\text{H}$  have a prophylactic action on benzpyrene cancer. H. G. R.

**Carcinogenic power of methylcholanthrene.** J. MAISIN and M. L. COOLEN (Compt. rend. Soc. Biol., 1936, 123, 159—160).—Methylcholanthrene is particularly active in producing cancerous tumours. H. G. R.

**Differentiation of tumours (carcinomata and sarcomata) of varying origin and investigation of the relationship between primary tumours and their metastases by the protective proteinase reaction.** E. ABDERHALDEN (Fermentforsch., 1936, 15, 245—250). E. A. H. R.

**Action of tumour tissue on hexosediphosphoric acid.** K. TSUZUKI (J. Biochem. Japan, 1936, 23, 421—435).—In rabbits' spindle-cell sarcoma, hexosediphosphoric acid yields triosephosphoric acid which does not form (from 2 mols.) phosphoglyceric (I) (1 mol.) and glycerophosphoric acid (1 mol.). The tumour tissue converts (I) into phosphopyruvic acid but not  $\text{AcCO}_2\text{H}$  except in presence of adenosinetriphosphoric or adenylic acid or phosphatase. The conversion of  $\text{AcCO}_2\text{H}$  into lactic acid (II) was not observed, but small amounts of (II) are always produced. The metabolism of the tumour is compared with that of muscle. F. O. H.

(A) Copper content of human tumours in relation to that of the liver. W. GERLACH. (B) Copper content of Jensen sarcoma in relation to that of the organs. S. EDLBACHER and W. GERLACH (Z. Krebsforsch., 1935, 42, 290—294, 272—289; Chem. Zentr., 1936, i, 574).—(A) Spectrographic determinations show the Cu content of tumours to vary within wide limits ( $0.5-20 \times 10^{-6}$  g. per g. fresh wt.). Liver contains  $4-19 \times 10^{-6}$  g. per g. (b) Rat livers contained 1—6, spleen 0.3, and kidneys  $3.4 \times 10^{-6}$  g. per g. fresh wt. Necrotic and healthy areas of Jensen tumour contained 0.73 and  $0.32 \times 10^{-6}$  g. per g., respectively. A. G. P.

**Intermediary fat and carbohydrate metabolism of sarcomatous rats.** B. PURJESZ and S. LAJOS (Magyar orvosi Arch., 1936, 37, 69—74).—The development of Jensen sarcoma in rats was associated with a fall in blood-sugar from 99 mg. per 100 ml. before inoculation to 60 mg. at 3—4 weeks. Liver-glycogen declined, on the average, from 1.58 to 0.43% and total carbohydrate of the liver from 3.5 to 2.1%.

The corresponding average figures for muscle were: glycogen 0.88 to 0.68%, total carbohydrate 2.0 to 1.5%. Neutral fat increased in the liver from 0.57 to 1.3, sterols from 0.35 to 0.54, and phosphatides from 2.7 to 3.1%. The I val. of liver fat was not significantly altered. NUTR. ABS. (m)

**Celiac disease. I. Carbohydrate metabolism.** E. BADENOCH and N. MORRIS (Quart. J. Med., 1936, 5, 227—250).—The flat blood-sugar curve was found only in active stages of celiac disease in children (7 cases). In convalescent periods the normal type of curve was approached. The curve was low in normal children of < 4 years, in marasmic children, and in cretins. The absorption and excretion of urea in celiac cases, and the absorption of sugar given with fat in normal children, indicate that fermentation of carbohydrate in the intestine is an important factor in the production of the flat curve in celiac disease. After 4 units of insulin injected subcutaneously in the fasting state in celiac disease, the blood-sugar fell to a mean val. of 33 mg. per 100 ml. in 1 hr. as compared with 67 mg. in normal children, but there were no clinical signs of hypoglycemia. Injection of anterior pituitary extract in cases of the disease caused a rise in the fasting blood-sugar and an increase in the height of the curve. Injections of extract of anterior pituitary improved the utilisation of fat in 3 cases of the disease. It is suggested that in the disease there is a deficiency of the contrainisular pituitary hormone. NUTR. ABS. (m)

**Mechanism of increased oxygen consumption in patients with cardiac disease.** H. RESNIK, jun., and B. FRIEDMAN (J. Clin. Invest., 1935, 14, 551—562). CH. ABS. (p)

**Nutritional factors which produce cataract and dermatitis.** A. F. MORGAN and B. B. COOK (Proc. Soc. Exp. Biol. Med., 1936, 34, 281—285).—In rats a diet containing 70% of lactose caused development of cataract in every case when the vitamin- $B_2$  content of the diet was low and in 85% of the cases when it was high. In no case was there development of dermatitis. A diet containing 68% of maize starch caused severe dermatitis when the  $B_2$  content was low but not when it was high. Administration of flavin cured the dermatitis. W. McC.

**Effects of excessive ingestion of sodium and potassium salts on carbohydrate metabolism and blood pressure in diabetic children.** I. McQUARRIE, W. H. THOMPSON, and J. A. ANDERSON (J. Nutrition, 1936, 11, 77—101).—Daily ingestion of 1—2 g. of NaCl per kg. body-wt. had a favourable effect on the carbohydrate metabolism of diabetic children receiving a simplified low-K diet. Other Na salts have similar though less marked effects. KCl has the reverse action on glycosuria and blood pressure. K completely antagonises the effects of Na when given simultaneously in amounts corresponding with 1/3 of the equiv. of Na ingested. A. G. P.

**Products of carbohydrate metabolism in the blood of diabetics. Residual chromic index.** H. WAREMBOURG (Ann. Méd., 1936, 39, 342—356).—The difference between the total chromic index and the glucose chromic index (I.C.G.) is called the

residual chromic index (I.C.R.) The I.C.R. represents chiefly carbohydrate degradation products such as lactic acid and  $\text{AcCO}_2\text{H}$ . The ratio I.C.G.:I.C.R. was normally 0.18–0.4. The I.C.R. was increased in untreated diabetes and the increase was not due to blood-ketones. I.C.R. was increased in diabetic blood after sugar ingestion and decreased by 75% after insulin (I) injection. No alteration took place in the normal individual. It is concluded that there is an increase in the intermediary products of carbohydrate metabolism in diabetes. Dietetic treatment and (I) therapy resulted in a decrease in I.C.R.

Nutr. Abs. (m)

**Serum-lipins in diabetes.** E. B. MAN and J. P. PETERS (J. Clin. Invest., 1935, 14, 579–594).—Cholesterolaemia (I) and phospholipinaemia were closely correlated in diabetics. Relation between (I) and the serum-fatty acids was less definite. Serum-cholesterol was unrelated to the severity of diabetes. Hypocholesterolaemia was associated with malnutrition and with hypoproteinaemia.

Ch. Abs. (p)

**Cholesterol content of blood in diabetic patients on fat-rich diets.** R. H. FREYBERG, L. H. NEWBURGH, and W. A. MURRILL (Arch. Int. Med., 1936, 58, 589–597).—In 21 patients with controlled diabetes fed on diets rich in fat for periods of 2 months to 8 years, the cholesterol (I) vals. during fasting were 0.126–0.223% (average 0.176%). With normal controls the vals. were 0.130–0.186%, average 0.156%. There was no correlation between the amount of fat in the diet and blood-(I). Lack of control of the disease is the main factor in causation of hypercholesterolaemia in diabetics.

J. N. A.

**Exercise in diabetes mellitus.** A. MARBLE and R. M. SMITH (Arch. Int. Med., 1936, 58, 577–588).—Exercise of short duration producing only mild fatigue markedly increased the blood-sugar of young diabetics (severe or moderate) who had not received food or insulin for several hr. Exercise probably causes glycogenolysis in the liver.

J. N. A.

**Eczema in nickel platers.** N. S. VEDROV (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 179–196).

M. A. B.

**Composition and changes in blood and spinal fluid in epilepsy.** I. I. BAN (Curierul farm., 1935, 5, No. 8, 1–17; Chem. Zentr., 1936, i, 584–585).—A relation is established between carbohydrate metabolism and the onset of epilepsy.

A. G. P.

**Fluorine in the bones and teeth in fluorosis.** J. M. MUNOZ (Compt. rend. Soc. Biol., 1936, 123, 74–75).—In rat fluorosis a diminution in the ash of the teeth and bones together with a three-fold increase in F was observed. Treatment with Ca, vitamin-D, and parathyroid hormone had no effect on the dental lesions.

H. G. R.

**Influence of blood-serum of goitre patients on tissue respiration.** K. MUNE (Folia Endocrinol. Japon., 1934, 10, 69–70).—Serum contains a substance (I) which accelerates  $\text{O}_2$  consumption in surviving rat tissue. The (I) content of serum increases in hyper- and decreases in hypo-thyroidism and approaches normal vals. with thyroid correction.

Ch. Abs. (p)

**Relation between the occurrence of endemic goitre and the presence of traces of silver and barium in drinking-water.** C. H. BOISSEVAIN and W. F. DREA (Endocrinol., 1936, 20, 686–687).—Ag is present in traces in drinking- $\text{H}_2\text{O}$  from both goitrous and non-goitrous areas.  $\text{H}_2\text{O}$  from the Swiss goitrous area shows an unusually high Ba content, but neither Ag nor Ba affects development of goitre when fed to rats.

R. N. C.

**Oxygen utilisation, cardiac output, and related circulatory functions in Graves' disease.** S. A. GLADSTONE (Proc. Soc. Exp. Biol. Med., 1936, 34, 587–591).—In 4 cases with basal metabolic rates of +33%, the arterio-venous  $\text{O}_2$  difference was decreased by 37%, whilst cardiac output increased by 93%.

P. G. M.

**Blood-sugar tolerance test in hypertension.** K. MAEHARA (Folia Endocrinol. Japon., 1934, 10, 52).—Hyperglycaemia following administration of glucose was higher and of longer duration in hypertensive cases.

Ch. Abs. (p)

**Hermaphroditism with growth disturbance.** M. SAKAMOTO, S. ITO, and H. HATTORI (Folia Endocrinol. Japon., 1934, 10, 59–60).—Growth disturbances are attributed to functional derangement of thyroid and sex glands. Blood-sugar was normal but tolerance was lowered. Basal metabolism was normal but the sp. dynamic protein metabolism was low.

Ch. Abs. (p)

**Hermaphroditism.** K. NISHIDA and J. MATSUI (Folia Endocrinol. Japon., 1934, 10, 60–61).—In the case described sugar tolerance and blood-sugar were almost normal; basal metabolism and sp. dynamic action were somewhat lowered.

Ch. Abs. (p)

**Pathological physiology of infarcts. IV. Arginase in necrosis.** H. BAYERLE, G. BORGER, and T. MAYR (Z. physiol. Chem., 1936, 243, 227–236).—The arginase (I) content of experimental anaemia-infarct of rabbit's kidney is < that of the healthy tissue and decreases progressively to zero in 10–14 days. At first the (I) content is raised by activation with  $\text{Fe}^{++}$  and  $\text{Mn}^{++}$  but these have no effect later. During autolysis the (I) content of healthy tissue decreases in the same way and is similarly affected by  $\text{Fe}^{++}$  and  $\text{Mn}^{++}$ .

W. McC.

(A) Cholesterol fractions in acute infections of infants with and without eczema. (B) Iodine value of serum-fatty acids in acute infections of infants with and without eczema. A. V. STRESSER (Proc. Soc. Exp. Biol. Med., 1936, 34, 10–11, 12–14).—(A) In fasting infants, the cholesteryl ester of the blood during acute infection of the respiratory tract was < during convalescence, but the free cholesterol underwent little change except in cases of pneumonia. (B) During the febrile period, the amount and I val. of the serum-fatty acids decreased.

W. O. K.

**Significance of carbohydrate metabolism and local acidosis in inflammation.** V. MENKIN and C. R. WARNER (Proc. Soc. Exp. Biol. Med., 1936, 34, 594–596).—The cytological picture in inflammation is conditioned by  $p_{\text{H}}$ , which is influenced by

increased glycolysis and local depletion of the alkali reserve.

P. G. M.

**Hyperproteinæmia with reversal of the albumin-globulin ratio in lymphogranuloma inguinale.** R. D. WILLIAMS and A. B. GUTMAN (Proc. Soc. Exp. Biol. Med., 1936, 34, 91—94).—Ten out of 12 cases of lymphogranuloma inguinale showed a hyperproteinæmia. There was an abs. and relative increase in serum-globulin in 11 cases.

W. O. K.

**Serum reaction in leprosy.** (A) Flocculation reaction. (B) Kephalin as flocculation reagent. I. SAKAKIBARA (J. Biochem. Japan, 1936, 23, 377—420, 437—448).—(A) The use of preps. containing lecithin as antigen in serological reactions for leprosy is discussed. The principal antigenic factor in nerve extracts, lecithin preps., etc. is kephalin (I).

(B) The antigenic action (which is due to the  $\beta$ - and not the  $\alpha$ -form) of (I) is unchanged by heating at 37° or 56° for 1 hr. or at 100° for  $\frac{1}{2}$  hr., by the presence of small amounts of  $\text{Et}_2\text{O}$ , by oxidation ( $\text{KMnO}_4$ ) or reduction ( $\text{Pt-H}_2$ ). The (I) from ox brain, ox liver, or hens' eggs contains 81, 76, and 79% of  $\beta$ -(I), respectively.

F. O. H.

**Cholesterol fractions in leprosy plasma.** G. G. VILLELA and A. CASTRO (Compt. rend. Soc. Biol., 1936, 123, 433—435).—Variations in the cholesterol fractions in the different clinical forms are discussed.

H. G. R.

**Multiple myeloma. IX. Crystalline and amorphous Bence-Jones protein.** A. MAGNUS-LEVY (Z. physiol. Chem., 1936, 243, 173—188).—The cryst. form of the protein (I) from 3 new cases was identical with that of (I) from 8 previous cases. It is not yet certain that (I) is a chemical entity.

W. McC.

**Myotonia.** W. R. RUSSELL and E. STEDMAN (Lancet, 1936, 231, 742—743).—Myotonia may be due to excessive production or accumulation of acetylcholine at the motor nerve-endings. It is increased by administration of prostigmine or a K salt, and temporarily relieved by  $\text{EtOH}$ .

L. S. T.

**Investigation of the origin of urinary protein in nephritis by the protective proteinase reaction.** H. HARTMANN (Fermentforsch., 1936, 15, 183—190).

E. A. H. R.

**Amino-nitrogen of nephritic transudates.** H. A. BULGER (Proc. Soc. Exp. Biol. Med., 1936, 34, 221—222).—The average  $\text{NH}_2\text{-N}$  contents of serum and transudates of patients with nephritis do not differ appreciably from those of non-nephritic persons, showing that rapid extravascular proteolysis does not occur in nephritis.

W. McC.

**Sodium chloride restriction and urea clearance in renal insufficiency.** E. M. LANDIS, K. A. ELSOM, P. A. BOTT, and E. SHIELS (J. Clin. Invest., 1935, 14, 525—541).—On a const. diet and fluid intake restricted intake of  $\text{NaCl}$  was accompanied by slightly diminished urea clearance (24 hr.). Administration of  $\text{NaCl}$  lowered plasma-urea (I) and increased the clearance. In advanced renal insufficiency (I) decreased markedly on administration of  $\text{NaCl}$ ; acute  $\text{NaCl}$  restriction produced hypochlor-

æmia with temporary retention of urea, creatinine, and  $\text{PO}_4'''$ .

CH. ABS. (p)

**Kidney function in children. I. Urea clearance values** (a) with no evidence of kidney disease, (b) after acute hæmaturic nephritis, (c) in the acute stage of the nephritis. G. E. CULLEN, W. E. NELSON, and F. E. HOLMES (J. Clin. Invest., 1935, 14, 563—574).—Vals. for normal children and adults and nephritic children show no fundamental differences.

CH. ABS. (p)

**Role of certain inorganic elements in the cause and prevention of perosis.** H. S. WILGUS, jun., L. C. NORRIS, and G. F. HEUSER (Science, 1936, 84, 252—253).—Perosis is due to lack of certain elements, especially Mn, and is aggravated by excess of Ca and probably of P. Al and Zn have a less effective preventive action than Mn.

L. S. T.

**Alteration in content of alkaline-earth metals in pathological body-fluids.** S. TOMISAWA (Mitt. med. Akad. Kioto, 1936, 17, 340—341).—The Ca and Mg contents of exudates, transudates, and sera from patients had some relationship to the course of their illnesses. In many cases during recovery, Ca increased and the Mg decreased, whilst when the condition became worse, Ca usually decreased and Mg increased.

NUTR. ABS. (m)

**Ascorbic acid excretion in pneumonia and other pathological conditions.** J. G. M. BULLOWA, I. A. ROTHSTEIN, H. D. RATISH, and E. HARDE (Proc. Soc. Exp. Biol. Med., 1936, 34, 1—7).—In pneumonia and other fevers urinary excretion of ascorbic acid following administration of large doses of vitamin-C is abnormally low.

W. O. K.

**Nervous system during pregnancy.** H. RASCHBA (Ukrain. Biochem. J., 1936, 9, No. 1, 55—68).—During pregnancy the creatine and  $\text{H}_2\text{O}$  content of the brain of rabbits is normal but the total N appears to be slightly reduced. In guinea-pigs' brain pregnancy produces no change in creatine, total N, or  $\text{H}_2\text{O}$  content.

W. O. K.

**Glutathione. I. Total and reduced glutathione, oxygen content and capacity, and cell volume of blood in non-pregnant and pregnant women with special reference to toxæmias of pregnancy.** F. W. OBERST and E. B. WOODS (Amer. J. Obstet. Gynecol., 1935, 30, 232—236; cf. A., 1935, 1392).—No essential differences were found in the total or reduced glutathione (I) or %  $\text{O}_2$  saturation of normal, pregnant, or parturient women. In the puerperium total (I) decreased slightly. Vals. were unaffected by late pregnancy toxæmias. The %  $\text{O}_2$  saturation was increased by use of anæsthetics containing  $\text{O}_2$  and was somewhat higher in non-convulsive toxæmias.

CH. ABS. (p)

**Diagnosis of pregnancy by the S. African clawed toad (*Xenopus laevis*).** H. A. SHAPIRO and H. ZWARENSTEIN (S. African Med. J., 1935, 9, 202—205).—The  $\text{Et}_2\text{O}$  extract of acidified urine is treated with  $\text{EtOH}$  and the centrifuged and washed ppt. is dissolved in  $\text{H}_2\text{O}$  and injected into toads.

CH. ABS. (p)

**Aschheim-Zondek [pregnancy] test.** J. B. DAWSON (New Zealand Med. J., 1935, 34, 22—25).—Urine for this test may be preserved by addition of  $\text{H}_3\text{BO}_3$  (20 grains per oz.). CH. ABS. (p)

**Kidney function during normal pregnancy.** M. NICE (J. Clin. Invest., 1935, 14, 575—578).—Urea (I) clearance during pregnancy is  $>$  normal and is not affected by increasing the blood-(I) by feeding (I). CH. ABS. (p)

**Fasting ketosis in the pregnant rat as influenced by adrenalectomy.** E. M. MACKAY and R. H. BARNES (Proc. Soc. Exp. Biol. Med., 1936, 34, 682—683).—Pregnant rats develop a ketosis  $>$  that in non-pregnant animals. It is abolished by adrenalectomy. P. G. M.

**Respiration and glycolysis in normal and pathological skin with special reference to psoriasis.** A. BUHMANN (Biochem. Z., 1936, 247, 145—152).—Anaerobic glycolysis in healthy human skin is relatively vigorous and the  $\text{O}_2$  consumption is low. Glycolysis probably occurs under aerobic conditions also. In psoriasis the  $\text{O}_2$  consumption increases on the average about 27% and the glycolysis about 68%. The age of the diseased skin has no effect on  $\text{O}_2$  consumption or glycolysis. Aerobic glycolysis occurs in psoriatic skin. Increases in  $\text{O}_2$  consumption and glycolysis  $<$  those observed in psoriasis are observed in other pathological affections of the skin. W. MCC.

**Dust in Mansfeld lung affections.** W. GEISLER (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 87—116).—The dust from the Mansfeld cupriferous slate workings contains much quartz (I) and mica (II), that from the overlying sandstone-shale mixture much (I) and feldspar (III). Affected lung tissue showed much (I) and (III), a little (II) and rutile, and very little sericite (IV). It is improbable that (IV) is the main causal agent of these affections. In studies on the individual cell (various bacteria) dusts of Si compounds showed no toxic effect; sol. Si compounds showed only low toxicity, decreasing in the order K silicate, Na silicate, aq.  $\text{SiO}_2$ , sol. glycol silicate. True solubility in  $\text{H}_2\text{O}$  at  $p_{\text{H}}$  7.6 is shown only with clay and asbestos but not with any of the constituents of the Mansfeld slate. M. A. B.

**Dust-affected lungs. II. Silica and titanium contents of lungs from 100 cases of dust affection.** G. GERSTEL (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 304—348).—The intensity of the lung affections did not appear to depend only on the  $\text{TiO}_2$ ,  $\text{SiO}_2$ , or ash content of the lung, although the heaviest deposits were found in the more severe cases. M. A. B.

**Asbestosis bodies.** P. J. BEGER (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 349—392).—The capsule of asbestosis bodies consists of protein and not  $\text{SiO}_2$  (cf. Koppenhofer, A., 1935, 1022). The  $n$  of the Fe-free capsule is  $\gg$  that of  $\text{SiO}_2$  gels and is practically the same as that of the blood corpuscles and tissue particles in microscopic preps. The capsule shows similar solubility in acids and alkalis to blood corpuscles and tissue particles, and is combustible. Koppenhofer's technique is criticised and the unreliability of the I-azide reaction for protein is pointed

out. The mechanism of the deposition of the protein capsule on the asbestos needle is discussed. M. A. B.

**Idiopathic steatorrhoea with multiple nutritional deficiencies.** H. W. FULLERTON and J. A. INNES (Lancet, 1936, 231, 790—792).—A case report with evidence of a deficiency of Ca, Fe, anti-anæmic factor, vitamin-B complex, and -C and -D. A possible deficiency of -A and -E is discussed. L. S. T.

**Differential glycaemia in pulmonary tuberculosis following administration of glucose-insulin.** R. DEL ZOPPO (Arch. Farm. sperim., 1936, 62, 1—16).—Mild forms of the disease do not affect carbohydrate metabolism in man. Initially the venous and capillary blood-sugar levels differ both during fasting and after administration of glucose. The non-occurrence of this difference in advanced cases excepting after injection of insulin and the prolonged alimentary glycaemia curve indicate hypofunction of the pancreas. F. O. H.

**Ascorbic acid metabolism in tuberculosis.** F. H. HEISE and G. J. MARTIN (Proc. Soc. Exp. Biol. Med., 1936, 34, 642—644).—55—138 mg. of ascorbic acid daily are required to bring a tuberculous patient into equilibrium as regards vitamin-C nutrition (normal is 15—20 mg.). P. G. M.

**Euglobulin in human serum in different forms of pulmonary tuberculosis.** J. VIGNATI and M. RAUCHENBERG (Compt. rend. Soc. Biol., 1936, 123, 167—168).—The val. is independent of that of the other protein fractions of the serum. H. G. R.

**Peptic ulcer following loss of pancreatic secretion through a fistula.** M. T. HOERNER (Amer. J. Digest. Dis. Nutrition, 1935, 2, 302—305).—Following the production of a pancreatic fistula, the  $p_{\text{H}}$  of gastric contents was unchanged but that of the duodenum after fasting varied somewhat, and reached a low level after ingestion of protein or carbohydrate. CH. ABS. (p)

**Influence of chemical thought on biology.** (SR) F. G. HOPKINS (Science, 1936, 84, 255—260).—A lecture. L. S. T.

**Carbon dioxide diffusion through human skin.** H. HAEUSSLER (Pflüger's Arch., 1935, 237, 448—453). M. A. B.

**Effect of oxygen inhalation on gaseous distension of the stomach and small intestine.** J. FINE, J. B. SEARS, and B. M. BANKS (Amer. J. Digest. Dis. Nutrition, 1935, 2, 361—367).— $\text{H}_2$  is much more readily absorbed from the gastro-intestinal tract than is  $\text{N}_2$ . Pure  $\text{O}_2$  inhalation does not increase absorption of  $\text{H}_2$ . The efficiency of  $\text{O}_2$  for absorption of intestinal gases  $\propto [\text{O}_2]$ . CH. ABS. (p)

**Ultracentrifugation and oxygen consumption of the eggs of *Ascaris suum*.** G. C. HUFF and E. J. BOELL (Proc. Soc. Exp. Biol. Med., 1936, 34, 626—628).—Respiration in *Ascaris* eggs is lowered by centrifuging. Respiratory and cleavage processes are not associated. P. G. M.

**Gaseous metabolism of the mammalian heart in sufficiency and insufficiency.** K. GOLLWITZER-MEIER, K. KRAMER, and E. KRÜGER (Pflüger's Arch.,

1936, 237, 68—92).—The gaseous metabolism of the heart increases with increased load whether due to increased resistance (aortic pressure) or increased inflow, but differs in the two cases. In both, the efficiency increases to a max. and then decreases. In spontaneous insufficiency the  $O_2$  utilisation increases for a given load, whilst the efficiency decreases; the optimum efficiency shifts towards the region of lighter load. The arterial  $O_2$  tension varies with the magnitude of the heart minute-vol. and the ventilation of the lungs, decreasing with decreased ventilation and *vice versa*. Increased resistance first decreases and then increases the capillary  $O_2$  utilisation in the heart-muscle. M. A. B.

**Effect of training on the respiration of muscle-tissue.** E. T. SORENI (Ukrain. Biochem. J., 1936, 9, 193—203).—The semitendinosus and biceps femoris muscles of rabbits, after short faradic stimulation for 15 min. daily for 15 days, show a large increase in respiratory activity compared with control muscles. The effect with the red muscle is < with the white muscle. F. A. A.

**Fasting and realimentation in the ruminant.**  
I. **Effect of food and fasting on certain blood constituents.** II. **Calcium and phosphorus metabolism during fasting, and during realimentation followed by fasting.** F. X. AYLWARD and J. H. BLACKWOOD (Biochem. J., 1936, 30, 1819—1824, 1824—1832).—I. Lipin-P decreases, and acid-sol. inorg. and org. P increase, in the blood of cows during fasting. Other blood constituents remain practically const., in contrast with the effects observed with single-stomached animals.

II. During prolonged fasting (12 days) Ca and P continue to be excreted by cows, and the data indicate that they are derived from both bone and phosphoprotein. F. A. A.

**Effect of excessive dietary sodium chloride on liver- and muscle-glycogen in the rat.** D. G. CRABTREE and B. B. LONGWELL (Proc. Soc. Exp. Biol. Med., 1936, 34, 705—707).—High NaCl content of the diet causes a large increase in liver- but has little effect on muscle-glycogen. P. G. M.

**Calcium content of the body in relation to the calcium and phosphorus content of the food.** L. B. WHITCHER, L. E. BOOHER, and H. C. SHERMAN (J. Biol. Chem., 1936, 115, 679—684).—Diets containing 0.42% of P and with Ca:P=1.2—2.4 or containing 0.73% of P and with Ca:P=0.7—1.4 do not increase the rate of calcification in rats; this effect is opposite to that found with diets containing 0.42% of P and with low Ca:P ratios (0.16—0.5) (A., 1931, 1326). F. A. A.

**Effect of liberal intakes of calcium or calcium and phosphorus on growth and body-calcium.** E. W. TOEFFER and H. C. SHERMAN (J. Biol. Chem., 1936, 115, 685—694).—Increasing the Ca or Ca+P contents of adequate diets results in more rapid growth and rate of calcification in rats, including those of the second generation. The max. effect is obtained at about 0.64% of Ca. F. A. A.

**Protein intake in relation to growth and rate of calcification.** R. T. CONNER and H. C. SHERMAN

(J. Biol. Chem., 1936, 115, 695—706).—With diets of approx. min. adequate Ca content (0.2%), raising the protein (I) level from 14% to 28% promotes growth and calcification in young rats. At higher Ca levels, increasing (I) to 25% gives a further increase in growth; further increase of (I) in the diet to 40% does not enhance this effect.

F. A. A.

**Effect of digestibility on the availability of iron in whole wheat.** E. McC. VAHLTEICH, M. S. ROSE, and G. MACLEOD (J. Nutrition, 1936, 11, 31—36).—Hæmoglobin regeneration in depleted rats receiving a whole milk diet was influenced by supplements in the order predigested wheat > natural fine-ground wheat > minerals ( $FeCl_3$ ,  $CuSO_4$ ). Ease of digestion contributed largely to the val. of predigested wheat. A. G. P.

**Protein utilisation as affected by the presence of small amounts of bran or its fibre.** E. H. FUNNELL, E. McC. VAHLTEICH, S. O. MORRIS, G. MACLEOD, and M. S. ROSE (J. Nutrition, 1936, 11, 37—45).—Of the total N intake of human subjects the proportion excreted when prepared bran was added to the diet was > when the fibre from the same amount of bran was used and, in turn > when no supplement was given. Feeding of vitamin-B with the fibre did not affect these results. Bran decreased the digestibility coeff. of the ration, the difference being attributable to excretion of bran protein. A. G. P.

**Specific dynamic action of carbohydrate and of protein in human hypothyroidism after total ablation of the normal thyroid gland.** M. LANDOWNE (J. Clin. Invest., 1935, 14, 595—603).—Ingestion of carbohydrate (I) or of protein (II) after complete removal of the thyroid is followed by an increased  $O_2$  consumption, thus demonstrating sp. dynamic effects of (I) and (II). CH. ABS. (p)

**Effect of high-protein diets on the kidney function in dogs.** L. K. CAMPBELL (J. Lab. Clin. Med., 1935, 20, 1162—1163).—No disturbance followed prolonged use of a diet containing 5 g. of protein per kg. live wt. with adequate supplies of other nutrients. CH. ABS. (p)

**Absorption of undigested proteins in man.**  
IV. **Absorption of unaltered egg-protein in infants and in children.** S. J. WILSON and M. WALZER (Amer. J. Dis. Children, 1935, 50, 49—54).—Absorption of unchanged egg-protein is a normal function in infants, children, and adults. CH. ABS. (p)

**Protein with sulphur-containing amino-acids suitable for feeding experiments.** Y. KOTAKE, jun., H. NAKATA and F. FUJIKAWA (Z. physiol. Chem., 1936, 243, 270—271).—The failure of *Pisum sativum*, L., to maintain growth is counteracted by addition of 0.5% of *l*-cystine or 0.625% of *l*-methionine. The proteins of the bean, legumin (I), vicilin, and legumelin, contain respectively 0.46, 0.26, and 1.1% of S. (I) and its acid hydrolysate contain insufficient S for maintenance of growth. The hydrolysate is rendered capable of maintaining growth by addition of *l*-cystine but not by that of *l*-tryptophan. W. McC.

**Amino-acid contents of eggs and chicks. Relation to diet and to incidence of chondrodystrophy.** A. R. PATTON and L. S. PALMER (J. Nutrition, 1936, **11**, 129—134).—The glycine (I) content of chondrodystrophic embryos was < normal. Synthesis of (I) occurs during embryonic development. Feeding (I) to hens did not affect the (I) content of eggs. Large doses were toxic. The  $\text{NH}_2$ -acid distribution in eggs from hens receiving optimum or deficient diets revealed no significant influence of diet on the composition of egg-proteins.

A. G. P.

**Intermediary metabolism of tryptophan.** XVIII. Mechanism of kynurenine production from tryptophan. I. Y. KOTAKE and T. MASAYAMA [with C. ITAGAKI]. XIX. *d*-Indolyl-lactic acid. K. ICHIHARA and H. NAKATA. XX. Production of indole from tryptophan derivatives by *B. coli*. XXI. Biological production of *d*-tryptophan. S. MAJIMA. XXII. Difference between rats and mice in the utilisation of tryptophan and its derivatives. Y. KOTAKE, K. ICHIHARA, and H. NAKATA. XXIII. Production of kynurenine acid by various animals. K. ICHIHARA and S. GOTO. XXIV. Haematopoietic action of tryptophan. T. HAMADA (Z. physiol. Chem., 1936, **243**, 237—244, 244—246, 247—250, 250—253, 253—256, 256—258, 258—265).—XVIII. Fresh rat's and rabbit's liver and liver extracts convert *l*-tryptophan (I) into kynurenine (II) and prokynurenine (III), whilst the boiled extracts convert *l*-(I) into (III) only. *d*-(I) yields (III) but not (II). (II) yields aminoacetophenone (IV) on heating in solutions slightly alkaline with  $\text{Ba}(\text{OH})_2$  but (III) gives (IV) only when heated with conc. aq.  $\text{K}_2\text{CO}_3$ . Hence the power of liver and liver extracts to convert (III) into (II) is destroyed by heating. Optimal conditions for the production of (II) and (III) from *l*-(I) by liver are: temp.  $37.5^\circ$ ,  $p_{\text{H}}$  6.5, concn. of *l*-(I)  $0.04M$ , and an  $\text{O}_2$  atm. (III) is probably the lactam corresponding to (II) and is produced from the first decomp. product of *l*-(I), namely 2-hydroxytryptophan.

XIX (cf. A., 1931, 513). *dl*-Indolyl-lactic acid (V) with quinine in MeOH gives a salt,  $[\alpha]_D$  approx.  $-104.5^\circ$  in MeOH, which on decomp. with HCl and extraction with  $\text{Et}_2\text{O}$  yields *d*-(V), m.p.  $97-100^\circ$ ,  $[\alpha]_D +5.18^\circ$  in  $\text{H}_2\text{O}$ . *d*-(V) replaces (I) in the diet of rats, being about twice as effective for growth as *ddl*-(V).

XX. *B. coli* convert *l*-(I) quantitatively and *d*-(V) almost quantitatively into indole, which is not produced from *l*-(V) and only slightly from indolepyruvic acid.

XXI. When *dl*-(I) is treated with *B. coli* at  $p_{\text{H}}$  7.2 the *l*-form is converted into indole which is removed with  $\text{Et}_2\text{O}$  and a 66% yield of *d*-(I) is obtained. Similarly *d*-2-methyltryptophan, m.p.  $231^\circ$ ,  $[\alpha]_D +18.78^\circ$  in  $\text{H}_2\text{O}$ , is obtained in 72% yield from the *dl*-form.

XXII. In rats *d*- and *dl*-(I) and *l*-(V) are utilised almost equally well, the utilisation of *dl*-(V) being poor, whereas in mice *l*-(I) and *l*-(V) are utilised whilst *d*-(I) and *d*-(V) are not. Probably the power of the rat to convert (V) into indolepyruvic acid is > that of the mouse. When the diet is poor in cystine, rats utilise methionine much better than do mice.

XXIII. After administration of (I), kynurenine acid (VI) occurs in human urine but not in the urine and bile of the cat and hen or in human bile. (VI) is found in small amounts in the urine and bile of rats and mice and in very small amounts in the bile of guinea-pigs after administration of (I).

XXIV. A diet free from (I) produces, in rats and mice, anaemia which is readily cured by subcutaneous administration of *l*-, but not *d*-, (I) which also stimulates growth. *l*-(I) given orally also cures the anaemia, but is more effective in stimulating growth. The effect of *l*-(I) given in successive small doses is that observed when one large dose is given. W. McC.

**Comparison of glycine and guanidinoacetic acid as precursors of creatine.** M. BODANSKY [with V. B. DUFF and C. L. HERRMANN] (J. Biol. Chem., 1936, **115**, 641—652).—Creatine (I) fed to rats transiently increases the (I) level of muscle, liver, and kidney; the guanidinoacetic acid (II) (traces of which normally occur in kidney and alimentary tract but not heart, muscle, and liver) levels remain unchanged. Following administration of (II), considerable amounts of (II) appear in liver and kidney (but not in muscle), up to 50% is excreted unchanged, whilst kidney- and urine-(I) increase. Methylation of (II) possibly occurs in the kidneys. No evidence of glycine being a precursor of (I) was obtained (cf. this vol., 369).

F. O. H.

**Synthesis of creatine during protein inanition.** G. MOUROT (Bull. Soc. Chim. biol., 1936, **18**, 1513—1523).—The sum of the amounts of creatine-N in the excreta of rats during, and in the bodies of rats after, periods of total or protein inanition is > that originally present.

A. L.

**Origin of urinary creatinine.** A. GOUDSMIT, jun. (J. Biol. Chem., 1936, **115**, 613—625).—The "apparent" creatinine (I) content of venous blood of dogs is consistently < that of arterial blood, the difference agreeing with the theory that the substance in blood responsible for Jaffe's reaction is the precursor of urinary (I). The excretion of this chromogenic substance is probably similar in the first stages to that of ingested (I).

F. O. H.

**Fate of protamines in the fertilised egg.** K. FELIX, L. BAUMER, and E. SCHORNER (Z. physiol. Chem., 1936, **243**, 43—56). The spermatozoa and eggs of herrings and the eggs of the rainbow trout contain dipeptidase (I) and arginase (II) and the spermatozoa of the trout contain (II). Trypsin, cathepsin, and polypeptidase are absent. Trout's eggs, 18 hr. after fertilisation, contain (I) which disappears in about 7 days and (II) which first decreases in amount and then increases as the egg develops. On fertilisation and during development the arginine (III), tyrosine, cystine (IV), and histidine (V) contents of the eggs remain almost const. whilst the tryptophan (VI) and lysine (VII) contents decrease. The protamine (VIII) of trout's eggs closely resembles clupeine, its chief constituent being (III). The spermatozoa contain, in addition to (VIII), (IV)—(VII), and other  $\text{NH}_2$ -acids.

W. McC.

**Fat metabolism in fishes. X. Hydrogenation in the fat depots of the tunny.** J. A. LOVERN

(Biochem. J., 1936, 30, 2023—2026).—The component fatty acids of the fats from the flesh, liver, pyloric caeca, heart, and spleen of the tunny, *Thunnus thynnus*, exhibit peculiarities probably characteristic of the tunny family such as lack of  $C_{14}$  acids, low palmitoleic (I) and high palmitic (II) and stearic acid (III) contents. The content of (III) of the different fats inversely  $\propto$  the degree of unsaturation of the remaining  $C_{18}$  acids and simultaneous hydrogenation of oleic acid and polyethylenic acids ( $C_{18}$ ) is suggested as the explanation. Hydrogenation of (I) to (II) and of unsaturated  $C_{20}$  acids to arachidic acid also occurs. It is suggested that by hydrogenation the content of saturated acids is maintained roughly const. and at a higher level than is usual for fish fats, possibly because of the warm habitat of the tunny and of the fact that its body-temp. is somewhat  $>$  that of the  $H_2O$ . P. W. C.

**Role of the liver in fat metabolism. Lipase action.** J. BENEDIOT (Arch. exp. Path. Pharm., 1936, 182, 537—549).—The serum-lipase activity of normal and diseased men is practically const. for each individual. The activity is increased by ingestion of fat (the increase being due to liver-lipase) and diminished by that of carbohydrate, whilst that of fat + carbohydrate has no significant effect, indicating antagonism between their hepatic catabolisms. F. O. H.

**Metabolism of ethyl esters of fatty acids.** H. J. DEUEL, jun., L. HALLMAN, J. S. BUTTS, and S. MURRAY (Proc. Soc. Exp. Biol. Med., 1936, 34, 669—671).—When the Et esters of odd C chain acids were fed, only small amounts of ketones are excreted. Acetonuria after administration of esters of acids with  $\leq 8$  C is  $>$  that of  $CH_3Ac \cdot CO_2$  controls. P. G. M.

**Effects of increased metabolism on the ketone body excretion of depancreatized dogs.** S. B. BARKER (Proc. Soc. Exp. Biol. Med., 1936, 34, 893—897).—Increased metabolism always takes place at the expense of fat oxidation and ketone formation. P. G. M.

**Role of phosphorus in carbohydrate and fat absorption processes.** S. E. EPELBAUM (Ukrain. Biochem. J., 1936, 9, 409—420).—A review. F. A. A.

**Carbohydrate metabolism.** H. WEIL-MALHERBE (Nature, 1936, 138, 551; cf. this vol., 1412).—Succinic acid is formed from  $AcCO_2H$ ,  $AcOH$ , and  $\alpha$ -ketoglutaric acid (I) both anaerobically in minced brain and aerobically in minced brain poisoned with malonic acid. The decarboxylation of (I) by brain-tissue under anaerobic conditions depends on the presence of suitable H acceptors. Evolution of  $CO_2$  is increased by addition of brilliant-cresyl-blue and reduced to normal when the dye is decolorised. The mechanism of decarboxylation is discussed. L. S. T.

**Carbohydrate metabolism.** G. K. MCGOWAN and R. A. PETERS (Nature, 1936, 138, 552).—Using avitaminous pigeon's brain tissue, no increased or decreased vitamin- $B_2$  effect was observed by adding  $\alpha$ -ketoglutaric (I) to pyruvic acid (II). The extra  $O_2$  uptake catalysed by  $-B_1$  in presence of (II) in

these brain systems does not follow the equation (cf. this vol., 1412)  $(I) + \text{ketonic acid} + H_2O \rightarrow \text{succinic acid} + CO_2 + \text{"OH"-acid}$ . L. S. T.

**Carbohydrate metabolism of the isolated cat liver.** E. LUNDGAARD, N. A. NIELSEN, and S. L. ØRSKOV (Skand. Arch. Physiol., 1936, 73, 296—313).—Although the perfused rabbit liver stores glycogen (I) from glucose (II) that of the cat does not; as with the rabbit liver addition of insulin has no effect. Fructose (III) and lactic acid (IV) are stored as (I) in perfused liver from normal cats or from cats depancreatized 48 hr. previously. It is supposed that hexoses must be first converted into (IV) before giving rise to (I) in the mammalian liver, and that the inability of the isolated cat liver to form (I) from (II) is due to its lack of power to convert (II), but not (III), into (IV). NUTR. ABS. (m)

**Carbohydrate metabolism of kidney.** M. J. LAWSON (Biochem. J., 1936, 30, 1996—2003).—In excised rabbit's kidney added  $0.5M$ - $NaF$  inhibits production of lactic acid (I) but does not affect liberation of  $PO_4^{'''}$  and  $0.01M$ - $KCN$  at  $p_H$  7.0 does not affect production of (I) or  $PO_4^{'''}$  liberation. At  $p_H$  7.0  $0.01$ — $0.02M$ - $CH_3I \cdot CO_2Na$  inhibits (I) production in the cortex and in 3 hr. at  $37.5^\circ$  decreases the (I) content but does not affect  $PO_4^{'''}$  liberation. Large amounts of (I) are produced by the cortex from glucose, smaller amounts from glycogen (II), still less from fructose, and none from galactose and mannose; from hexose mono- and di-phosphate a little (I) is sometimes produced. (II) of the cortex is insufficient to account for the (I) produced in 2 hr. at  $37.5^\circ$ . Glycolysis in the cortex is not accelerated by  $0.002M$ - $AsO_4^{'''}$ . The cortex readily reduces  $AcCO_2H$  to (I) and  $AcCO_2H$  may be an intermediate in glycolysis. W. McC.

**Carbohydrate metabolism of warm-blooded animals during muscular work.** E. JOKL (Klin. Woch., 1935, 14, 1139—1143; Chem. Zentr., 1936, i, 101—102).—In rats moderate muscular work lowered the lactic acid content of the muscle and liver and increased that in blood. Exhaustive work lowered all vals., which increased again during rest (without food). The depot-glycogen content of organs decreased during work; blood-sugar was unchanged by moderate exercise but declined with exhaustion. The phosphagen content increased in exhausted animals. A. G. P.

**Significance of histotrophy in the carbohydrate metabolism of the foetus within the uterus.** B. SZENDI and G. PAPP (Orvosi Het., 1935, 79, 890—895).—The decidua of man, rats, and rabbits contain relatively large amounts of glycogen, which diminish during pregnancy. Nutrition of the foetus depends on the combined effects of histotrophy and haemotrophy. CH. ABS. (p)

**Carbohydrate oxidation in hypophysectomised rats.** R. E. FISHER and R. I. PENCHARZ (Proc. Soc. Exp. Biol. Med., 1936, 34, 106—107).—As compared with normal rats hypophysectomised rats continue to oxidise carbohydrate (I) for a longer time during fasting with a slightly higher R.Q., and they

derive a larger proportion of their energy from (I) after glucose feeding. W. O. K.

**Glycogen of frog's liver and muscle after subcutaneous injection of sugars.** A. MOSCHINI (Compt. rend. Soc. Biol., 1936, 123, 119—121).—Injection of glucose, fructose, galactose, or maltose increases glycogen, whilst sucrose or lactose has little effect. H. G. R.

**Mechanism of glycogenolysis.** J. K. PARNAS and P. OSTERN (Bull. Soc. Chim. biol., 1936, 18, 1471—1492).—Theoretical. A. L.

**Site of formation of conjugated glucuronates in the organism.** F. SCHMID (Compt. rend. Soc. Biol., 1936, 123, 223—226).—The liver is the chief site. H. G. R.

**Respiratory exchange in children following administration of various carbohydrates: relation to curves for blood-sugar.** J. L. LAW and H. GAY (Amer. J. Dis. Children, 1935, 50, 375—384).—The increase in R.Q. in the first 30 min. after ingestion of carbohydrates was highest for sucrose, followed, in descending order, by galactose, glucose, lactose, fructose, and dextri-maltose. The max. increase in heat production in this period appeared simultaneously with the peak of the blood-sugar curve. No parallelism was apparent between the max. vals. for R.Q. and blood-sugar.

CH. ABS. (p)

**Metabolism of galactose. III. (1) Lactose synthesis from (a) a glucose-galactose mixture, (b) phosphoric esters, by slices of the active mammary gland *in vitro*. (2) Effect of prolactin on lactose synthesis by the mammary gland.** G. A. GRANT (Biochem. J., 1936, 30, 2027—2035).—When glucose (I)-galactose (II) mixtures are used as substrates for lactating mammary tissue *in vitro*, lactose (III) synthesis is not noticeably increased beyond that for (I) alone and direct coupling of (I) and (II) does not appear to be the mechanism of (III) formation. An active  $\beta$ -galactosidase could not be detected in preps. of the lactating gland. (I) 6-phosphate, fructose 6-phosphate or 1:6-diphosphate, (II) 6-phosphate, and phosphoglyceric acid also did not give increased (III) synthesis, although the slices were active when (I) was substrate. NaF (0.04M) and  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{Na}$  (0.02M) inhibit almost completely both (I) utilisation and (III) synthesis by slices of lactating tissue. The *in vivo* synthesis of (III) was re-established to a limited extent in the inactive regressing mammary glands of guinea-pigs by prolactin. The induced secretion resembled milk in appearance but had a low (III) content (0.04—0.24%). P. W. C.

**Intravenous galactose liver-function test.** I. R. JANKELSON and H. H. LERNER (Amer. J. Digest. Dis. Nutrition, 1934, 1, 310—312).—The rate of utilisation of galactose (I) by the liver may be ascertained by periodic measurements of blood-(I) following intravenous injection. In cases of demonstrable liver damage (I) is metabolised more slowly.

CH. ABS. (p)

**Absorption of glucose and water from chronic isolated loops of the colon.** P. H. MOORE and G. E. BURGET (Amer. J. Digest. Dis. Nutrition, 1934,

1, 376—382).—Optimal absorption of glucose (I) occurs with 5—10% solutions. Small amounts of NaCl do not affect, but  $\text{NaHCO}_3$  retards, absorption of (I). Optimal absorption of  $\text{H}_2\text{O}$  takes place from 0.9% aq. NaCl; it is inhibited by 2.5% aq. (I) and with 10% solutions there is a definite  $\text{H}_2\text{O}$  influx. Small quantities of  $\text{NaHCO}_3$  in an isotonic solution of (I) cause an influx of fluid into the intestine. Blood-sugar is not a true index of sugar absorption from the intestine when the amount absorbed is small.

CH. ABS. (p)

**Absorption of glucose and galactose from dog's intestine.** F. A. CAJORI and W. G. KARR (Amer. J. Med. Sci., 1935, 189, 880—881).—When both sugars were inserted into loops of the jejunum glucose (I) was absorbed more rapidly than galactose (II), the total carbohydrate absorption remaining about the same as when either sugar was given separately. Absorption rates were the same for each sugar administered alone.  $\text{PO}_4'''$  did not accelerate absorption of (I), (II), or fructose. CH. ABS. (p)

**Oxidation of glucose in presence of insulin etc. and probable mechanism of biological oxidations.**—See this vol., 1491.

**Relations between liver function and metabolism of fructose. I—VI.** Y. IIDA (Japan. J. Gastroenterol., 1934, 6, 61—93).—Impaired liver function is examined by means of blood-fructose curves after parenteral administration of fructose (I). Intestinal absorption of (I) is inhibited by hepatic disturbances. CH. ABS. (p)

**Metabolism of fructose. IX. Effect of endocrine dysfunction on tolerance.** A. W. ROWE, M. A. MCMAHON, A. J. PLUMMER, and G. A. RILEY (Endocrinol., 1936, 20, 648—656).—The deviations of fructose tolerance from the normal vary considerably with the endocrine disturbance. The extent of agreement with the deviations of galactose tolerance also shows wide variations. R. N. C.

**Production of hexose monophosphate and its conversion into fructose diphosphate in muscle.** P. OSTERN, J. A. GUTHKE, and J. TERSZAKOWEC (Z. physiol. Chem., 1936, 243, 9—37).—Dialysed extract of autolysed rabbit's muscle even when 8 days old produces large yields of hexose monophosphate (I) from glycogen (II) and inorg.  $\text{PO}_4$  (but not from glucose and inorg.  $\text{PO}_4$ ), the process not being dependent on the presence of co-enzyme. When excess of (II) is present all the inorg.  $\text{PO}_4'''$  is consumed and when excess of inorg.  $\text{PO}_4'''$  is present all the (II) is consumed. In extracts inactivated with  $\text{CH}_2\text{I}\cdot\text{CO}_2\text{H}$  and NaF deamination of adenosinetriphosphoric acid (III) is greatly accelerated by (I) and (II) [but not by fructose diphosphate (IV)], which act as  $\text{PO}_4$  acceptors. In fresh or reactivated extracts which produce lactic acid (V) the deamination of (III) is inhibited by (IV) > (I) > (II) because phosphopyruvic acid, the sp.  $\text{PO}_4'''$  donor for rephosphorylation of adenylic acid, is produced. (I) is converted by (III) into (IV), probably by direct transfer of  $\text{PO}_4'''$  from (III) to (I). (I) is not phosphorylated by inorg.  $\text{PO}_4'''$ . Phosphorylation of (II) by  $\text{PO}_4'''$  and the transfer of the P-containing residue from (III) to (II) are inhibited

by 0.01M-phloridzin, which also greatly checks hydrolysis of (III) to adenylic acid (VI) and  $H_3PO_4$  but scarcely checks the transfer of  $IO_4'''$  from (III) to (I). Hence deamination of (III) is much more rapid when (I) is present than when it is replaced by (II). In the degradation of (II) to (V) the first stages are  $(II) + H_3PO_4$  yielding (I) followed by  $(I) + (III) + H_2O$  giving  $(IV) + H_3PO_4 + (VI)$ , no  $H_3PO_4$  being liberated at any stage. In the degradation of (I) to (V) 0.5 mol. and in the degradation of (IV) to (V) 1 mol. of  $H_3PO_4$  per mol. of (V) are liberated, respectively.

W. McC.

**Action of pilocarpine and potassium on phosphorylation in muscle.** J. WAJZER and R. LIPPMANN (Bull. Soc. Chim. biol., 1936, 18, 1428—1435).—Whilst pilocarpine and  $K^+$  increase the decomp. of phosphagen (I) in normal frog's muscle, the contents of adenosinetriphosphoric acid and hexose esters remain const. In the presence of  $CH_3I \cdot CO_2H$ , however, the (I) content is affected only by  $K^+$ .

A. L.

**Carbohydrate resynthesis in the liver.** H. VON EULER and G. GÜNTHER (Z. physiol. Chem., 1936, 243, 1—8).—About 50% of cozymase (I) added to sliced rat's liver is inactivated in 4 hr. Lactate (II) and pyruvate (III) added together with (I) to slices of rat's and guinea-pig's liver in  $O_2$  disappear and the carbohydrate (IV) content increases in parallel or the consumption of (IV) which normally occurs when nothing is added is decreased. [No consumption of (IV) occurs when the (IV) content of the slices is very low.] When the amount of added (I) is increased the amount of (IV) synthesised and the amount of (II) which disappears increase. Probably (II) is converted by (I) into (III).

W. McC.

**Deuterium as an indicator in the study of intermediary metabolism.** VII. Bile acid formation. R. SCHOENHEIMER, D. RITTENBERG, B. N. BERG, and L. ROUSSELOT (J. Biol. Chem., 1936, 115, 635—640; cf. A., 1935, 1407).—Following intravenous injection of 4:5-dideuterocoprostanone (I) into dogs with biliary fistulae, a D-containing unsaponifiable substance [probably (I)] occurs in the bile whilst cholic acid (II) from the bile is free from D. Hence coprostanone is probably not an intermediary in the hypothetical conversion of cholesterol into (II).

F. O. H.

**Lactic acid metabolism of the heart in spontaneous insufficiency and in poisoning by sodium fluoride, iodoacetic acid, and euphylline.** F. GOTTDENKER and C. J. ROTHBERGER (Pflüger's Arch., 1936, 237, 59—67).—In spontaneous insufficiency, in spite of coronary dilatation, the heart-muscle takes up less lactic acid (I) than normally and may even liberate it into the blood. In  $NaF$  poisoning, although (I) formation is inhibited, utilisation of the preformed (I) is not increased but often sinks to zero. With  $CH_3I \cdot CO_2H$  and euphylline there is a marked, protracted dilatation of the coronary vessels, but (I) uptake is increased only for a short time, after which it decreases until liberation into the blood takes place.

M. A. B.

**Role of the 4-carbon dicarboxylic acids in muscle respiration.** J. M. INNES (Biochem. J.,

1936, 30, 2040—2048).—Methods for determination of fumaric (I), succinic (II), malic (III), oxaloacetic (IV), and pyruvic acid (V) are worked out. Addition of 2 mg. of (I) to 0.4 g. of minced pigeon breast muscle suspended in  $PO_4'''$  buffer ( $p_H$  7) caused an increase in respiration during which some of the added (I) disappeared and was not found again either as (II) or (IV). During incubation of the muscle with (I) in  $O_2$ , (IV) and (V) show a slight increase. The amount of (III) accumulating depended on the degree of oxygenation, none being obtained in  $O_2$  but appreciable amounts in air. The latter amounts appeared, however, to have no fixed relationship to the amount of (I) present. The entire O uptake was never > could be accounted for by oxidation of some of the (I) disappearing. In experiments with washed tissue, (I) is oxidised in preference to lactic acid in equiv. concn. The results suggest that (I) is being utilised as a substrate for respiration and not as a catalyst for transference of O to other substrates in the muscle.

P. W. C.

**Ketogenesis—antiketogenesis.** III. Metabolism of aldehydes and dicarboxylic acids. IV. Substrate competition in liver. N. L. EDSON (Biochem. J., 1936, 30, 1855—1861, 1862—1869).—III. Rat liver slices are able anaerobically to form acid probably by dismutation from  $MeCHO$ ,  $EtCHO$ ,  $PrCHO$ ,  $Bu^oCHO$ , and  $Bu^sCHO$  but not from hex-, hept-, and oct-aldehydes. Under aerobic conditions all these aldehydes are ketogenic except  $EtCHO$ , the ketone formation being of the same order as that with the corresponding fatty acids. With dicarboxylic acids and their derivatives there is increased  $O_2$  consumption and the acids are neither ketogenic in livers of well nourished nor antiketogenic in livers of starved animals. Exceptions to this rule are malonic, hydroxymalonic, and mesoxalic acids which are strongly, and tartaric and oxalic acids which are weakly, ketogenic.

IV. Antiketogenesis is studied in liver slices of starved and well nourished rats in presence of added fatty acids. The rate of ketone formation is the outcome of competition between fatty acids and other oxidisable substrates for the oxidising systems of liver. Carbohydrates and their derivatives, e.g., lactate, pyruvate,  $CO(CH_2 \cdot OH)_2$ , alcohols, certain  $NH_2$ -acids, and particularly glycerol and sorbitol are antiketogenic substances. The fatty acids also compete amongst themselves.

P. W. C.

**Degradation of fenchone in the animal organism.**—See this vol., 1514.

**Active water and salt transport through the frog's skin.** E. HUF (Pflüger's Arch., 1936, 237, 143—166).—Identical salt solutions separated by a frog's skin soon show differences in salt concn. which are increased when  $Na$  lactate or pyruvate is added to the solutions. When  $KCN$  is added the effect is either inhibited or reversed. Transport of  $H_2O$  and salts through the skin by an "active" energy-consuming process is probable.

M. A. B.

**Permeability to ions of the isolated frog's heart.** G. ORZECOWSKI (Arch. exp. Path. Pharm., 1936, 183, 77—86).—Washing of the heart with

normal (frogs) Ringer's solution after a period of washing with K-free Ringer's solution temporarily depresses cardiac activity due to action of  $K^+$  which diffuses from perfusion fluid to heart-muscle or *vice versa*. Diffusion of  $Ca^{++}$  from salt solutions to heart-muscle does not occur. The "threshold" val. of  $[K^+]$  of perfusing fluids at which  $K^+$  is neither given up to nor taken from frog's heart-muscle is approx. 0.009%. The K content of dried frog's heart-muscle is 1.4—1.7%. F. O. H.

**Phosphates and work.** E. ATZLER, K. BERGMANN, O. GRAF, H. KRAUT, G. LEHMANN, and A. SZAKALL (Arbeitsphysiol., 1935, 8, 621—694; Chem. Zentr., 1936, i, 372).—Daily variations in the P balance in man and in dogs are examined. The min. P requirement of dogs is controlled by the metabolic level and not by body-wt. During exercise the P balance declines relative to the N balance for a time. Subsequent feeding of P lowers the N balance relative to that of P. Ca and P metabolism shows a similar relationship. The relative efficiency of org. and inorg. P is examined. In pregnancy with a levelled N balance, the P balance is negative during the first 19 weeks. Subsequently the P balance is positive and inorg. P is readily retained. A. G. P.

**Sodium-potassium antagonism and its significance in water metabolism.** C. DIENST (Arch. exp. Path. Pharm., 1936, 182, 567—576).—Examination of the urine of salt-treated men shows that  $Na^+$  displaces  $K^+$  from the organism and *vice versa* but whilst  $Na^+$  produces retention,  $K^+$  enhances excretion of  $H_2O$ . Administration of large doses of  $K^+$  to normal and ascitic men temporarily increases serum-K and subsequently urine-K and produces diuresis.

**Rate of water loss by man at rest. I. Constant-temperature and -humidity room. II. Spontaneous diuresis during prolonged rest.** P. D'A. HART and E. B. VERNEY (Clin. Sci., 1935, 1, 367—380, 380—396).—I. Experimental equipment is described.

II. During rest and fasting, spontaneous diuresis, commencing within 3—6 hr., is characterised by decreased urinary N and Cl and is inhibited by posterior pituitary extract. Relations between diuresis and the concn. of extract in the plasma are examined. CH. ABS. (p)

**Oxidation-reduction potential, action of fuadin, and duration of life in *Opisthorchis*, *in vitro*.** W. KOLLATH and A. ERHARDT (Biochem. Z., 1936, 287, 287—288; cf. Klin. Woch., 1935, 14, 1809).—The duration of life of the intestinal worm, *Opisthorchis tenuicollis felinus*, *in vitro* at 37° is maximal when the oxidation-reduction potential is  $-0.081$  (in neutral Ringer's solution diluted 1:50,000) and at this potential the sp. toxic effect of fuadin is maximal. The effect is minimal at a potential of  $+0.011$ .

W. MCC.

**Fate [in the organism] of complexes of citric acid with salts of heavy metals.** H. LANGECKER (Arch. exp. Path. Pharm., 1936, 182, 642—653).—The complexes [with citrate (I) in anionic form] of  $Fe^{III}$  and  $Co^{II}$  are less readily oxidised by  $O_2$  than is Na citrate. Liver or kidney pulp decomposes  $Fe^{III}$ ,

$Mn^{II}$ , or  $Co^{II}$  complex but not that of  $Ni^{II}$  or  $Cu^{II}$ . Following intravenous injection into rabbits of  $Fe^{III}$ ,  $Co^{II}$ , or  $Ni^{II}$  complex, a part of the metal appears in the urine; this occurs only slightly with  $Mn^{III}$  whilst with  $Fe^{III}$ , the Fe excretion is equivalently  $>$  that of (I) and (I) does not appear in the intestine. Absorption of (I) from enterally administered  $Fe^{III}$  complex occurs only very slowly. F. O. H.

**Fate of senna drugs in the organism.** H. GEBHARDT (Arch. exp. Path. Pharm., 1936, 182, 521—526).—Injection of senna glucosides (I) into cats is followed by urinary excretion of (I) and conjugated (sulphate and glycuronate) emodin (II); with continuous intravenous injection of (I) or (II), the excretion is mainly of conjugated (II). Ingestion of (I) by men is followed by excretion of conjugated (II) with traces of free (II) and of free and conjugated anthranol. F. O. H.

**Effect of X-radiation on the blood.** H. L. BROSE and E. B. JONES (Nature, 1936, 138, 687—688).—Irradiation by X-rays or Ra reduces the ratio erythrocyte-P: plasma-P in man. This change may serve as a measure of the effect of X-ray dosages.

L. S. T.

(A) Detection of mitogenetic rays with the help of a physical differential method. (B) Biological detection. W. W. SIEBERT and H. SEFFERT (Biochem. Z., 1936, 287, 92—103, 104—108).—(A). Further experiments (cf. A., 1933, 336) are described using two light quanta enumerating tubes, one registering the variation in the effect of cosmic rays, the other of cosmic + mitogenetic rays. Curves are given showing differences due to a no. of mitogenetic effects. The mitogenetic effect of normal blood is destroyed by the presence of KCN.

(B). The method depends on the inhibition by mitogenetic radiation of the rate of elimination of gas by a fluid yeast culture. The results by the method compare favourably with those by the above physical method. P. W. C.

**Influence of work and training on the oxidation-reduction potential of muscle-tissue.** R. TSCHAGOVETZ (Ukrain. Biochem. J., 1936, 9, 273—307; cf. A., 1935, 1522).—The biceps femoris muscle of rabbits, fatigued by electrical stimulation *in vivo* for 45 min., and similar muscles after training (similar stimulation for 20 min. daily for 15 days) yield extracts showing differences in oxidation-reduction potential compared with control muscles of the same animals. With fatigued muscle the initial val. of potential is more positive, and the fall to the same final val. takes longer, than with unfatigued muscle. Training results in a diminution of positive potential and a quicker attainment of the stable val. The  $p_H$  of extracts from fatigued muscles is  $>$ , and that of trained muscle  $<$ , those of their respective controls.

F. A. A.

**Effect of acid and basic fodder on oxidative processes in muscles during work and training.** M. F. GULI (Ukrain. Biochem. J., 1936, 9, 309—320).—Comparison is made between the rates of decolorisation of methylene-blue by the muscles of rabbits fed on acid and basic diets, and the effects of fatigue, training, and of training followed by fatigue, on these

muscles. In all cases the rate of decolorisation in the acid-fed animals is  $>$  that in the basic-fed, and the difference is greater in trained than in fatigued muscles. F. A. A.

**Influence of the acid-base ratio of foods on some physico-chemical properties and the capacity for work of isolated muscle.** G. BENETATO and N. MUNTEANU (Compt. rend. Soc. Biol., 1936, 123, 201—203).—The  $p_H$ , buffering power, and capacity for work are only slightly affected by the diet. H. G. R.

**Oxidation-reduction potential of muscle-tissue *in vivo*, *in situ*, and its functional variations.** V. V. KOVALSKI and O. M. GLEZINA (Ukrain. Biochem. J., 1936, 9, 205—271).—The oxidation-reduction potential of leg muscles of rabbits, determined directly *in situ*, shows small irregular fluctuations and long periodic asymmetrical fluctuations. The val. of  $E_h$  differs between right and left legs of the same animal, due to unequal distribution of glutathione.  $E_h$  of muscles trained by continuous electrical stimulation is  $\ll$  that of normal muscle. Fatigue raises  $E_h$  of normal muscle, but lowers that of trained muscle. Further complex phenomena are discussed. F. A. A.

**Osmotic pressure and muscular contraction.** I. CHAO (Chinese J. Physiol., 1936, 10, 547—558).—Parallel determinations of the contraction due to const. submaximal stimuli and of the wt. of the muscle preps. used (toad's sartorius) were made in solutions of varying osmotic pressure. The wt. of the muscle, after correcting for the wt. of osmotically inactive materials, is inversely  $\propto$  the osmotic pressure. A temporary increase in contraction occurs on increasing the osmotic pressure and *vice versa*. The contraction at osmotic equilibrium is max. in a slightly hypotonic solution. Within the limits of 4.3—8.5 atm., the contraction is a linear function of osmotic pressure. P. W. C.

**Chemical mediation of impulses in certain fibres of the splanchnic nerves.** G. V. RUND and F. M. KINROSS (Austral. J. Exp. Biol., 1936, 14, 193—198).—The pressor response to splanchnic stimulation in ergotoxinised dogs shows periodical alternations in character. It is influenced by the discharge of adrenaline from the gland and by the release of a pressor substance from some and of a depressor substance from other visceral terminations of the splanchnic nerve, not the adrenal. A. G. P.

**Effects of heat and humidity on the human body.** C. K. DRINKER (J. Ind. Hyg., 1936, 18, 471—485).—A summary of the effects of exposure to high temp. (periodic or continuous). The importance of controlling NaCl and H<sub>2</sub>O intake in cases of heat cramp and other conditions is stressed. Neither humidity nor sunlight is a prime factor; they merely intensify the effects of heat. P. G. M.

**Gastric motility under low oxygen pressures.** E. J. VAN LIERE (Amer. J. Digest. Dis. Nutrition, 1934, 1, 373—376).—Anoxæmia decreased motility. CH. ABS. (p)

**Action of the gases issuing from fire-damp pockets.** F. FLURY (Arch. Gewerbepath. Gewerbe-  
5 H

hyg., 1935, 6, 257—269).—A discussion. Although none of the constituents of 'fire-damp' is of high toxicity, long-continued exposure to them, together with the relative O<sub>2</sub> shortage occurring in mines, is probably responsible for the characteristic symptoms developed by coal-miners. M. A. B.

**Central-nervous regulation of the heart minute volume during breathing of air containing carbon dioxide.** O. DIEBOLD and O. MERTENS (Pflüger's Arch., 1935, 237, 585—589. M. A. B.

**Influence of water administration on oxygen consumption rate in shock.** H. A. DAVIS (Proc. Soc. Exp. Biol. Med., 1936, 34, 21—23).—In anaesthetised dogs in which shock had been induced by various means, intravenous administration of isotonic NaCl solution produced a rise in metabolism, less prolonged than that observed in normal anaesthetised animals. Whereas the latter tolerated isotonic NaCl solution up to 25% of the total body-wt., amounts equal to 5—12% of the body-wt. caused a fall in O<sub>2</sub> consumption in the shocked animals. W. O. K.

**Comparative action of mineral waters on the autonomous contraction of the ureter.** P. TESTONI (Annali Chim. Appl., 1936, 26, 370—384).—The action of various Italian mineral waters on the contraction of the guinea-pig's ureter was determined. Analytical data indicate that generally stimulation is due to CO<sub>2</sub> and Ca<sup>++</sup> and inhibition to NO<sub>3</sub><sup>-</sup>, Br<sup>-</sup>, H<sub>2</sub>S, and high concns. of Na<sup>+</sup> and Cl<sup>-</sup>. L. A. O'N.

**Presence of sterols in the mud of the salt lake of Tekirghiol (Dobrodgea) [Roumania].** N. L. COSMOVICH and J. S. ATANASIU (Bull. Soc. Chim. biol., 1936, 18, 1425—1427).—Extracts of the black mud give reactions for sterols. The therapeutic action is probably due to the sterol content. A. L.

**Pharmacology of the mineral water of Valle-verde.** P. TESTONI (Annali Chim. Appl., 1936, 26, 283—290; cf. A., 1935, 1023).—The H<sub>2</sub>O stimulates the germination of lupin seeds and the development of the plant, inhibits the movement of the epithelial cilia of the oesophagus of the frog, and stimulates the contraction of the ureter of the guinea-pig, and increases the tonus. L. A. O'N.

**Therapeutic effects of mineral waters.** A. KELLER (Mitt. Lebensm. Hyg., 1936, 27, 204—215).—A review. E. C. S.

**Feeding deuterium oxide to rats.** SIGNE SCHMIDT-NIELSEN and SIGVAL SCHMIDT-NIELSEN (Kong. Norske Vidensk. Selsk. Forhandl. 1935, 8, 27—28 Chem. Zentr., 1936, i, 360).—Apart from an initial period of increased thirst, D<sub>2</sub>O had no appreciable effect on growth or sexual development of the animals. A. G. P.

**Occurrence of acidosis after experimental ammonia poisoning.** N. ALWALL and E. GEIGER (Arch. exp. Path. Pharm., 1936, 183, 123—126).—Diminution of alkali reserve occurs in rabbits after introduction of aq. NH<sub>3</sub> into the stomach but not intestine. Hence the acidosis is not due to absorption of NH<sub>3</sub> (cf. Fazekas, this vol., 223). F. O. H.

**Methæmoglobin-producing action of sodium nitrite.** S. RAPPEPORT-LEWEY (Arch. Farm. speriment.,

1936, 62, 17—36).—Intravenous injection of lethal doses ( $>0.12$  g. per kg.) of  $\text{NaNO}_2$  into rabbits causes death during which methaemoglobin formation occurs to the extent of 67.5—99%. Differences in rate of formation between cats and rabbits are discussed.

F. O. H.

**Action of calcium salts on living tissue.** L. I. WEBER (*Cernauti Med.*, 1, No. 1, 57—59; *Chem. Zentr.*, 1936, i, 373).—The influence of Ca salts of org. and inorg. acids on the swelling of gelatin gels is examined and the special action of Ca gluconate (I) is observed. The effects of injecting (I) on the natural gel of living muscle are explained on this basis.

A. G. P.

**Determination of cardio-analeptic activity by means of the potassium-paralysed Straub frog's heart preparation.** F. HENDRYCH (*Arch. exp. Path. Pharm.*, 1936, 182, 738—748).—Heart preps. paralysed with 0.1% KCl solution are suitable for testing drugs owing to the paralysis being readily removed by washing with Ringer's solution. In restoring cardiac activity, adrenaline and caffeine and, to a smaller extent, "cardiazol" are effective; camphor, "coramin," ephedrine, and sympthol are not stimulatory but, at certain concns., paralytic.

F. O. H.

**Liberation of acetylcholine from perfused human placenta.** H. C. CHANG (*Proc. Soc. Exp. Biol. Med.*, 1936, 34, 665—666).—K<sup>+</sup> causes a transfer of acetylcholine (I) from tissue to fluid, whilst eserine and heat stimulate the formation of (I) by some unknown mechanism.

P. G. M.

**Magnesium sulphate and catharsis.** J. FERGUSON and A. C. IVY (*Proc. Soc. Exp. Biol. Med.*, 1936, 34, 720—722). Subcutaneous injection of aq. 25%  $\text{MgSO}_4$  does not cause catharsis by absorption into the blood followed by excretion into the colon, nor does it increase the excretion of Mg by the mucosa.

P. G. M.

**Influence of magnesium oxide on antipyretic action and toxicity of aspirin in rabbits.** D. R. CLIMENKO (*Proc. Soc. Exp. Biol. Med.*, 1936, 34, 807—812).—The toxicity of aspirin (I) is unaffected by simultaneous administration of  $\text{MgO}$ . (I) and  $\text{MgO}$  are synergic as regards their antipyretic action.

P. G. M.

**Influence of ethyl alcohol on energy metabolism of the mammalian heart.** H. C. PETERS, C. E. REA, and J. W. GROSSMAN (*Proc. Soc. Exp. Biol. Med.*, 1936, 34, 61—64).—The total energy output of the isolated mammalian heart, working at const. diastolic vol., diminishes under the influence of EtOH.

W. O. K.

**Liver-lipins of the white rat following chloroform poisoning, insulin administration, and fungus infection.** P. L. MACLAGHLAN (*Proc. Soc. Exp. Biol. Med.*, 1936, 34, 31—33).— $\text{CHCl}_3$  poisoning, insulin administration, or *Aspergillus* or *Sporothrix* infection produces no change in the lipin content of the livers of rats or in the ratio of phospholipin to neutral fat.

W. O. K.

**Physiological action of methylglyoxal.** E. MARTINI (*Arch. ital. Biol.*, 91, 173—184; *Chem. Zentr.*, 1936, i, 103).

A. G. P.

**Toxicology of the organic solvents. 1:4-Dioxan.** W. WIRTH and O. KLIMMER (*Arch. Gewerbepath. Gewerbehyg.*, 1936, 7, 192—206).—Dioxan, absorbed through the respiratory tract, is about as toxic as MeOH but considerably less toxic than  $(\text{CH}_2)_2\text{O}$ .

M. A. B.

**Oxidation-reduction processes in the inflammatory focus of the mucous membrane.** V. V. KOVALSKI, M. M. BUGAEVA, and O. M. GLEZINA (*Ukrain. Biochem. J.*, 1936, 9, 381—386).—Inflammation of the mucous membrane of the lip of a rabbit is accompanied by a change in oxidation-reduction processes, measured directly as  $E_h$ . Application of mustard gas to this membrane is accompanied by a fall in  $E_h$ , followed by a slow rise towards normal. This differs from the clinical picture.

F. A. A.

**Microscopy of fat absorption in the normal gut and inhibition by iodoacetic acid and phloridzin.** L. JEKER (*Pflüger's Arch.*, 1936, 237, 1—13).—Free fatty acids give positive staining reactions with Fischler's  $\text{Cu}(\text{OAc})_2$ -haematoxylin reagent and with Sudan III, neutral fats with Sudan III only. In the normal gut the first stage of absorption is the penetration of free fatty acids into the epithelial cells; later, synthesis of neutral fat occurs. In the poisoned gut penetration of fatty acids occurs but conversion into neutral fat is inhibited.

M. A. B.

**Effect of dinitrophenol on the metabolism of frog muscle.** E. RONZONI and E. EHRENFEST (*J. Biol. Chem.*, 1936, 115, 749—768).—2:4-Dinitrophenol (I) ( $5 \times 10^{-5}\%$ ) accelerates the  $\text{O}_2$  consumption of frog's muscle 6—10 times, glycogen being consumed. Caffeine has a similar effect, only slightly enhanced by (I). Treatment with  $\text{CH}_2\text{I} \cdot \text{CO}_2\text{H}$  reduces the effect of (I), which is partially restored by lactic acid (II). Anaerobic (II) production is accelerated 8—10 times, and continues until phosphocreatine (III) and adenosine phosphate are completely decomposed.  $\text{O}_2$  prevents (II) accumulation. (I) accelerates the rate of hydrolysis of (III), and the data indicate inhibition of its resynthesis. In muscle extracts, (I) increases the rate of  $\text{O}_2$  consumption, but does not affect the rates of production of (II) or of hydrolysis of (III). (I) appears to act by allowing a max. mobilisation of carbohydrate.

F. A. A.

**Action of 2:4-dinitrophenol on the oxidation-reduction potential of the aqueous humour and crystalline lens of the rabbit.** J. NORDMANN and P. REISS (*Compt. rend. Soc. Biol.*, 1936, 123, 233—234).—Injections increase the potential to vals. similar to that of  $\text{C}_{10}\text{H}_8$  cataract, no signs of which, however, are visible.

H. G. R.

**Increase in blood-polypeptides in phenylhydrazine-poisoned dogs.** A. VON JENEY and L. SOKORAY (*Arch. exp. Path. Pharm.*, 1936, 182, 560—566).—The normal level of blood-polypeptide-N of 0.0024—0.0060% rises to 0.0054—0.0082%, whilst the erythrocyte count diminishes.

F. O. H.

**Toxic effects of neutral diaminoacridine methochloride.** H. WAREMBOURG, J. DRIESSENS, and G. LABENNE (*Compt. rend. Soc. Biol.*, 1936, 123, 13—14).—Intravenous injection into the rabbit results in lesions in the lungs, adrenals, liver, kidneys,

and bone marrow, together with an increase in blood-urea and -polypeptides, and anæmia. Elimination appears to be through the liver and kidneys.

H. G. R.

**Preparation and therapeutic properties of certain acridine derivatives.**—See this vol., 1521.

**Helenalin, the bitter sternutative substance occurring in *Helenium autumnale*.**—See this vol., 1514.

***dl*-Methionine in developmental growth.** F. S. HAMMETT and K. PADIS (Proc. Soc. Exp. Biol. Med., 1936, 34, 181—183).—The early growth of *Obelia geniculata* is stimulated by very low concns. of *dl*-methionine (I). In the living organism (I) is possibly converted into cystine.

W. McC.

**Pressor effects of some new alkyl derivatives of  $\beta$ -phenylethylamine.** W. E. HAMBOURGER and R. B. JAMIESON, jun. (J. Pharm. Exp. Ther., 1936, 58, 53—61).—Me and Et derivatives are all less active than the parent substance, *p*-substitution reducing the duration of action. With *N*-Me a second *o*-Me or *p*-Et reduces the activity greatly, the latter sometimes showing a depressor action. The  $\text{NH}_2\text{Et}$  derivatives are depressor whatever the position of the substituted Me.

H. G. R.

**Vasomotor interference in the vascular network of the muscles during experimental hyperæmia produced by vaso-dilator substances.** F. GROSSE-BROCKHOFF, M. SCHNEIDER, and W. SCHOEDEL (Pflüger's Arch., 1936, 237, 178—189).—Adrenaline injected intravenously produced constriction in muscular blood vessels dilated by adenosine, adenylic acid, histamine, and glucose, but not after acetylcholine (I) dilatation. Resistance to vaso-constriction in the working muscle is probably due to the liberation of a substance [possibly (I)] as a result of the increased muscular activity.

M. A. B.

**Influence of vaso-dilator substances on the output of work and the blood supply, during work, in the skeletal muscles.** W. SCHOEDEL (Pflüger's Arch., 1936, 237, 190—212).—Acetylcholine, histamine, and adenylic acid all produced a further increase in blood supply in muscular vessels already showing hyperæmia due to work, but in no case did the increased blood supply result in a better output of work by the muscle. Probably none of these substances is involved in the hyperæmia of work.

M. A. B.

**Physiology and pharmacology of sterols. I. Cholesterol and sterol economy.** E. STARKENSTEIN. II. Significance of cholesterol in permeability and absorption. E. STARKENSTEIN and F. HENDRYCH. III. Influence of sterols on the cutaneous absorption of drugs from unguents. H. MATSCHAK. IV. Influence of cholesterol on the action of hypnotics and narcotics. V. Influence of cholesterol mobilisation by saponin on the action of soporifics. E. STARKENSTEIN and H. WEDEN (Arch. exp. Path. Pharm., 1936, 182, 654—663, 664—687, 688—699, 700—714, 715—719).—I. The physiological importance of sterols, especially cholesterol (I), is discussed.

II. The role of sterols, especially (I), in the influence

of cellular lipins on absorption of  $\text{H}_2\text{O}$ - and lipin-sol. substances and on cell permeability is discussed.

III. The theory that cutaneous absorption of drugs occurs more readily from salves of fat or lipin than from those of vaseline or paraffin could not be fully confirmed. The absorption of H and Na salicylate from lanoline and vaseline indicates that, in addition to the lipin- or  $\text{H}_2\text{O}$ -solubility of the drug, reactions with the base (e.g., esterification with sterol alcohols) or with cellular sterols influence the rate of absorption. Other factors include acidity of the salve and the sterol contents of salve and skin.

IV. Intraperitoneal injection of aq. emulsions of (I) or its esters into mice, rabbits, or guinea-pigs enhances the narcotic action of inspired  $\text{Et}_2\text{O}$  or  $\text{CHCl}_3$  or subcutaneously injected  $\text{Et}_2\text{O}$  and the soporific action of veronal etc. Orally administered (I) is ineffective. Oils and fats resemble (I) but are often more active enterally owing to increased absorption of the narcotic. The action of (I) in increasing localisation of lipin-sol. dyes in the brain of injected animals indicates that (I) aids in the transport of narcotics to the nervous tissues.

V. The enhancement of the soporific action of veronal by prior intravenous injection of aq. saponin (II) is due to mobilisation of body-(I) by (II). That bees' poison acts similarly to (II) indicates that it contains a (II)-like substance.

F. O. H.

**Inulin and its suitability for intravenous administration in man.** W. GOLDRING and H. W. SMITH (Proc. Soc. Exp. Biol. Med., 1936, 34, 67—68).—Certain purified samples of dahlia and chicory inulin (I), administered intravenously to man, produced marked toxic symptoms. This action is probably the result of overheating (I) during drying.

W. O. K.

**Effect of varying  $p_{\text{H}}$  on toxic effect of bile salts on the normal gall-bladder.** H. G. ARONSOHN and E. ANDREWS (Proc. Soc. Exp. Biol. Med., 1936, 34, 763—765).—The toxic action of bile salts on the normal gall-bladder is unaffected by change of  $p_{\text{H}}$  within the normal range of the bile.

P. G. M.

**Relative toxicity of different bile salts on the normal gall-bladder.** E. ANDREWS and H. G. ARONSOHN (Proc. Soc. Exp. Biol. Med., 1936, 34, 765—767).—Deoxycholic acid is the most toxic to the gall-bladder wall.

P. G. M.

**Effect of methylene-blue on respiration of blocked and developing embryonic cells.** J. H. BODINE and E. J. BOELL (Proc. Soc. Exp. Biol. Med., 1936, 34, 629—630).—Methylene-blue may act as a substitute for the part of the respiratory process impaired either naturally or by HCN.

P. G. M.

**Action of hæmatoporphyrin on blood-calcium and -phosphorus.** P. MABIQUE and G. MELOT (Compt. rend. Soc. Biol., 1936, 123, 280—283).—Ca is slightly lowered whilst changes in P are negligible.

H. G. R.

**Tissue response to subcutaneous injection of cod-liver oil.** J. DAVSON (Lancet, 1936, 231, 737—738).—Subcutaneous injection of fish-liver oils into rabbits produces a marked stimulation of phagocytes, fibroblasts, and young capillaries. Liquid

paraffin and olive oil are comparatively inert. The vitamin-A of the oils is not responsible for the reaction.  
L. S. T.

**Growth inhibitor in liver.** A. M. BRUES, E. B. JACKSON, and J. C. AUB (Proc. Soc. Exp. Biol. Med., 1936, 34, 270—273).—The growth of explants of embryonic and sarcomatous tissue is inhibited by the solution obtained when fresh, sterile liver is shaken with 2 vols. of Tyrode's solution. The inhibiting agent does not dialyse and is fairly stable to O<sub>2</sub> but not to heat.  
W. McC.

**Supplement to Steenbock diet 2965.** W. J. NIJVELD (Z. Vitaminforsch., 1936, 5, 257—262).—Addition of liver or liver extract to the diet prevented the unsatisfactory growth of rats, for there was a steady increase in wt. corresponding with an increased food intake. The deaths which frequently occurred after approx. 10 days on the ordinary diet were also prevented. The active factor of the liver is not in the ash, and it is not destroyed by heating dry powdered liver at 130° for 6 hr. Heating of liver extract in an autoclave at 120° did not completely remove the activity.  
J. N. A.

**Role of lactoflavin and flavinphosphoric acid in adrenal cortex deficiency and iodoacetic acid poisoning.** F. VERZAR and L. LASZT (Z. Vitaminforsch., 1936, 5, 265—275).—Adrenalectomised rats can be kept alive for > 2 months with yeast concentrates containing flavinphosphoric acid. Lactoflavin alone does not have this effect, and is unable, even in daily doses of  $2 \times 10^{-4}$  g., to cause growth in rats poisoned with CH<sub>2</sub>I-CO<sub>2</sub>H (I). Growth can take place as a result of refecation in rats suffering from chronic (I) poisoning.  
J. N. A.

**Chemical factors governing gastric motility.** J. P. QUIGLEY (Amer. J. Digest. Dis. Nutrition, 1934, 1, 425—426).—Fats and carbohydrates liberate humoral factors from the mucosa of the upper intestine which resemble an inhibitory hormone.

CH. ABS. (p)

**Anæsthetic activity of butanes and pentanes.** R. W. STOUGHTON and P. D. LAMSON (J. Pharm. Exp. Ther., 1936, 58, 74—77).—The activity and lethality of C<sub>4</sub>H<sub>10</sub> are < those of C<sub>5</sub>H<sub>12</sub> and those of the straight chain > those of the isomerides with branched chains.  
H. G. R.

**Local anæsthetic activity of quinoline compounds.** H. K. SINHA (J. Pharm. Exp. Ther., 1936, 58, 62—67).—Activity, both when applied to the mucous membranes and on intradermal injection, is observed on introducing a basic side-chain at 8.  
H. G. R.

**Influence of the anæsthetic on the results of digitalis assay by the cat method of Hatcher and Brody.** C. C. HASKELL (J. Pharm. Exp. Ther., 1936, 58, 111—117).—The cat unit with dial-urethane anæsthetic is > that with Et<sub>2</sub>O.  
H. G. R.

**Detoxication of local anæsthetics by "cardiazol."** K. ZIPF and H. HOPPE (Arch. exp. Path. Pharm., 1936, 183, 67—70).—The toxic effects of novocaine and larocaine in mice and cats are diminished by simultaneous injection of "cardiazol."  
F. O. H.

**Local anæsthetics containing the  $\alpha$ -tetrahydro- $\beta$ -naphthylamine pressor group.**—See this vol., 1501.

**Plasticity of skeletal muscle before and during deep narcosis.** A. HEINRICH (Pflüger's Arch., 1936, 237, 19—23).  
M. A. B.

**Blood-ammonia during ether narcosis in man.** L. STANOJEVITCH and S. PETKOVITCH (Compt. rend. Soc. Biol., 1936, 123, 430—432).—The increase is greater when the initial val. is high and after the anæsthesia remains at an increased level.  
H. G. R.

**Atropine-morphine-ether narcosis.** F. HENDRYCH (Arch. exp. Path. Pharm., 1936, 182, 732—737).—The narcotic action of Et<sub>2</sub>O on mice is enhanced by prior injection of morphine + atropine (I); (I) thus resembles scopolamine. The mechanism of the phenomenon is discussed.  
F. O. H.

**Sedative action of valerian.** H. DRUCKREY and G. KÖHLER (Arch. exp. Path. Pharm., 1936, 183, 106—109).—The narcotic effect of different types of extract of valerian from various sources was determined by the action on the head movements of mice. Infusions are most, and Et<sub>2</sub>O extracts least, active (cf. Kochmann and Kunz, this vol., 1022).  
F. O. H.

**Distribution of atebtrin in the organism.** G. HECHT (Arch. exp. Path. Pharm., 1936, 183, 87—105).—Data for the distribution of atebtrin (I) in cats and rabbits following administration by various routes are tabulated. The general tendency is for (I) to be most conc. in liver, lungs, heart, kidneys, and spleen and, to a smaller extent, in intestines, heart, pancreas, and reproductive organs. Intramuscularly injected (I) is detectable in the blood for only 1 hr. after injection.  
F. O. H.

**Effect of drugs on the Schlesinger reaction for urobilin.** J. J. HOFMAN (Pharm. Weekblad, 1936, 73, 1417—1421).—Acriflavine (I) when administered orally gives a positive Schlesinger test for urobilin in the urine [fluorescence when treated with EtOH-Zn(OAc)<sub>2</sub> suspension]. (I) is detected by treatment with NaOCl or KI-I solution, when a black ppt. is formed and the filtrate no longer fluoresces. Several precipitants for (I) are noted, the sensitivity being given in parentheses: 10% Na salicylate (1:10<sup>4</sup>), K<sub>3</sub>Fe(CN)<sub>6</sub> (1:10<sup>5</sup>), K<sub>4</sub>Fe(CN)<sub>6</sub> (1:10<sup>4</sup>), K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (1:10<sup>4</sup>), Na tungstate (1:10<sup>4</sup>), NH<sub>4</sub> molybdate (1:10<sup>4</sup>), HgCl<sub>2</sub> (1:10<sup>5</sup>).  
S. C.

**Endocrine localisation of medicinal and toxic substances.** R. FABRE (Ukrain. Biochem. J., 1936, 9, No. 1, 125—141).—Various toxic substances including CHCl<sub>3</sub>, C<sub>2</sub>H<sub>2</sub>Cl<sub>4</sub>, veronal, quinine, F<sub>2</sub>, and Cr are retained by the endocrine glands, on which they probably exercise a profound effect.

**Experimental hypertrophy with and without digitalisation on creatine content of rabbit hearts.** G. M. DECHERD, jun., G. HERRMANN, and E. H. SCHWAB (Proc. Soc. Exp. Biol. Med., 1936, 34, 864—866).—There is an abs. increase in the creatine content of hypertrophied hearts which is further increased by administration of digitalis.  
P. G. M.

Disturbance of protein metabolism following liver injury by salvarsan. A. WIEDMANN (Wien. klin. Woch., 1935, 48, 1539—1543; Chem. Zentr., 1936, i, 803).—Metabolism of protein but not carbohydrate is affected.

A. G. P.

Neuromuscular junction. II. Antagonism between calcium and curarising agencies. T. P. FENG (Chinese J. Physiol., 1936, 10, 513—527).—With nerve-sartorius preps. of the toad, Ca antagonises the curarising action of curare, eserine, veratrine, nicotine, atropine, ergotoxine, strychnine, pilocarpine, and novocaine, of fatigue and long survival, of Sr, Ba, and Mg, and of extreme temp. The immediate and reversible cause of curarisation appears to be an electrolytic disturbance involving the loss of Ca from the neuromuscular junction.

P. W. C.

Effect of calcium and curare on muscular contraction and neuromuscular transmission. I. CHAO (Chinese J. Physiol., 1936, 10, 545—546).—With sciatic-sartorius preps. of toad, excess of Ca decreases muscular contraction, whilst Ca antagonises the effect of curare and facilitates neuromuscular transmission.

P. W. C.

Action of ergometrine. K. K. CHEN, E. E. SWANSON, and C. C. HARGREAVES (Proc. Soc. Exp. Biol. Med., 1936, 34, 183—185).—Ergometrine nitrate (I) in a concn. of about 1:30,000 slightly stimulates the isolated rabbit uterus, having about 0.01% of the oxytocic activity of ergometrine (II). The action of (I) on the cock's comb is about 0.7% of that of (II). (I) relaxes isolated rabbit intestine and produces prolonged reduction of blood pressure in the cat.

W. McC.

Physico-chemical processes in nerve tissue. I. Oxidation-reduction potential in rabbit brain during strychnine and cocaine poisoning. S. V. FOMIN and D. N. STRAJESKO (Ukrain. Biochem. J., 1936, 9, No. 1, 43—54). The oxidation-reduction potential of rabbit brain tissue becomes stable more rapidly when from an animal poisoned with strychnine (I) or cocaine (II) than when normal. The potential of boiled brain tissue extract from rabbits poisoned with (I) is < that of a similar extract of normal tissue, but under anaerobic conditions the potentials of both boiled and unboiled extracts are higher from the poisoned than from normal animals. (II) poisoning also produces changes in the oxidation potentials of the extracts.

W. O. K.

Comparative action of cobra venom and morphine on the autoxidation of cerebral and other tissues. D. I. MACHT and H. F. BRYAN (Compt. rend. Soc. Biol., 1936, 123, 385—388).—The inhibition with venom is more prolonged than with morphine, since a modification of the alkaloid is observed if the time of contact is long.

H. G. R.

Poisons of animal origin. The venins. M. T. REGNIER (J. Pharm. Chim., 1936, [viii], 24, 368—375, 413—429).—A review.

Heart poisons and saponins of the cholane series. K. BOHLE (Chem.-Ztg., 1936, 60, 893—896).—A review.

Seeds of the Madagascar anthelmintic Combrataceæ. J. MAHEU and R. WERTZ (Bull. Sci. pharmacol., 1935, 42, 202—210; Chem. Zentr., 1936, i, 805).—The leaves of *Quisqualis indica*, L., and the fruits of *Q. madagascariensis*, Boj., and their application as anthelmintics are described.

H. N. R.

Physico-chemical mechanisms in convulsive reactivity. E. SPIEGEL and M. SPIEGEL-ADOLF (Proc. Soc. Exp. Biol. Med., 1936, 34, 799—800).—Epileptogenous agents act on the nervous system (a) by a change in ion concn. on the surface of the nerve cells and (b) by diminution of the cellular surface films.

P. G. M.

Chronic nicotine toxicity. I. Feeding of nicotine sulphate and tannate and bentonite. II. Effect of nicotine-containing diets on blood-sugar concentration in the rat. R. H. WILSON and F. DE EDS (J. Ind. Hyg., 1936, 18, 553—564, 565—570).—I. The growth of rats fed on a diet containing >0.006% of nicotine (I) was retarded; this retardation was largely due to diminished food intake and, in lesser degree, to the toxic effect of (I). (I) sulphate was approx. twice as toxic as the tannate or bentonite.

II. Chronic (I) poisoning produces an initial hypoglycæmia and acute intoxication a transient hyperglycæmia followed by a return to normal.

P. G. M.

Acute toxicities of rotenone and mixed pyrethrins in mammals. M. B. SHIMKIN and H. H. ANDERSON (Proc. Soc. Exp. Biol. Med., 1936, 34, 135—138).—The min. lethal doses of rotenone for guinea-pigs, rats, and mice were 7—10 mg. per kg. (intraperitoneally) and 75—100 mg. (orally). The corresponding vals. for mixed pyrethrins were 100—150 mg. and 1500 mg.

W. McC.

Toxicity of *d*- and *l*- $\alpha$ -tolylpyrrolidine to *Aphis rumicis*. Toxic constituents of derris root.—See B., 1936, 1117.

Acute intraperitoneal toxicity of plant growth-substances for mice. H. H. ANDERSON, M. B. SHIMKIN, and C. D. LEAKE (Proc. Soc. Exp. Biol. Med., 1936, 34, 138—139).—The min. lethal doses for mice of indolyl-propionic and -butyric acid and phenyl-,  $\alpha$ -naphthyl-, and indolyl-acetic acid were respectively 100, 100, 300, 100, and 25 mg. per kg. The toxicities of these substances to plants are approx. in the same relative order.

W. McC.

Alleged toxicity to rats of maize germ and its ethereal extract. E. CASERIO (Z. Vitaminforsch., 1936, 5, 263—265).—Maize germ and its ethereal extract have no action on rats, and they actually show favourable somatic effects. The contrary results of Randoïn and Simonnet may be explained either by fermentation of the extracts or by contamination with toxic material.

J. N. A.

Pathomorphological changes in the internal organs and endocrine glands in dinitrophenol poisoning. I. PEISSAKOVITSOH and P. KOSTENKO (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 160—170).

M. A. B.

Morphological and chemical investigations in a case of death from acute benzene poisoning.

G. F. KOPPENHOFER (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 417—427).— $C_6H_6$  was demonstrated in the blood and organs by distilling these with  $H_2O$  acidified with  $H_2SO_4$ , nitrating the distilled  $C_6H_6$ , and identifying the *o*- and *m*- $C_6H_4(NO_2)_2$  by the intense violet colour with fructose. M. A. B.

**Permeability of the cerebrospinal barrier and blood variations in experimental benzene poisoning.** S. B. SCHACHNOVSKAJA (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 144—156). M. A. B.

**Toxicity of propylene glycol.** H. A. BRAUN and G. F. CARLAND (J. Amer. Pharm. Assoc., 1936, 25, 746—749).—The min. lethal dose in rats is 15.7 and 23.1 g. per kg. for intramuscular and subcutaneous injection, respectively: corresponding vals. for glycerol are 7.6 and 15.1. The oral lethal dose of the glycol in rabbits is 20 g. per kg. but daily ingestion of 8 c.c. for 50 days has no cumulative effect. F. O. H.

**Chronic carbon tetrachloride poisoning.** J. LOWY (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 157—159). M. A. B.

**Chronic iodoacetic acid poisoning and its relation to the Gee-Herter disease.** L. LASZT and F. VERZAR (Pflüger's Arch., 1936, 237, 483—493).—Chronic  $CH_2I \cdot CO_2H$  poisoning produces in rats symptoms similar to those of the Gee-Herter disease. In the poisoned rats the symptoms can be removed by feeding dried yeast or vitamin- $B_2$  (flavin phosphate) but not by flavin. It is suggested that the symptoms are due, in both cases, to inhibition of  $-B_2$  formation from flavin. M. A. B.

**Mechanism of methylene-blue in carbon monoxide poisoning.** M. M. BROOKS (Proc. Soc. Exp. Biol. Med., 1936, 34, 48—49).—In rabbits poisoned with CO, the conversion of CO-haemoglobin into oxy-haemoglobin is definitely accelerated by intravenous administration of methylene-blue (1 c.c. of 0.03% solution per kg. body-wt.). W. O. K.

**Influence of liver poisons on action of parathyroid extract.** D. M. GREENBERG (Proc. Soc. Exp. Biol. Med., 1936, 34, 622—626).—Poisoning with P inhibits, and with  $N_2H_4$  markedly reduces, the serum-Ca rise following injection of parathyroid extract;  $CCl_4$  has no effect.  $N_2H_4$  and P do not act *via* the bone cells. P. G. M.

**Cyanide poisoning.** K. K. CHEN, C. L. ROSE, and G. H. A. CLOWES (Metal Ind., N.Y., 1936, 34, 346).—First-aid treatment with amyl nitrate and 1% aq.  $Na_2S_2O_3$  is described. L. S. T.

**Combined action of lead and nicotine.** R. M. SKLIANSKAJA (Arch. Gewerbepath. Gewerbehyg., 1935, 6, 270—274).—The combined toxic effect of Pb and nicotine (I) on the isolated frog's heart is < the sum of the toxic effects of Pb and (I) separately. M. A. B.

**Toxicity of selenium-containing plants to aphids.** A. M. HURD-KARRER and F. W. POOS (Science, 1936, 84, 252).—*Rhopalosiphum prunifoliae* (Fitch) is killed by the Se taken up by plants (wheat, rye, oats, and barley) from small amounts of  $Na_2SeO_4$  added to cultures or soils. L. S. T.

**Poisoning by sodium nitrite.** A. SCHOLLES (Analyst, 1936, 61, 685—686).—The  $NaNO_2$  had been mistaken for NaCl. The amounts present in the stomachs of the deceased and in the unconsumed food are recorded. E. C. S.

**Structure and toxicity of arsinic acids of the diphenylamine series.**—See this vol., 1527.

**Enzymes in relation to cancer.** A. PURR (Current Sci., 1936, 5, 194—196).—A review.

**Effect of irradiation with short waves on enzymes. I. Diastase.** K. KOSIERADSKI (Biochem. Z., 1936, 287, 265—270).—The saccharifying action of diastase alone or mixed with starch is not affected by irradiation with short waves (2, 4, 10, and 15 m.). W. McC.

**Keilin's cytochrome-c and the respiratory mechanism of Warburg and Christian.** H. THEORELL (Nature, 1936, 138, 687).—Cytochrome-c, like  $O_2$  and methylene-blue, does not oxidise the dihydroco-enzyme directly. It rapidly oxidises the leuco-form of the yellow enzyme. L. S. T.

**Action of cyanides on the purine dehydrogenase of milk.** E. J. BIGWOOD, J. THOMAS, and H. HERBO (Compt. rend. Soc. Biol., 1936, 123, 87—90).—The inhibiting effect of KCN is not observed under anaerobic conditions. H. G. R.

**Storch reaction [for peroxidase in milk].** L. C. JANSE (Chem. Weekblad, 1936, 33, 638—640).—Milk containing traces of Cu gives a positive Storch reaction [colour with  $p\text{-}C_6H_4(NH_2)_2$ , HCl, and  $H_2O_2$ ] even when pasteurised at  $> 85^\circ$ . The adverse effect of Cu is corr. by preliminary addition of 1 c.c. of 0.25% aq. KCN to 5 c.c. of milk. S. C.

**Behaviour of the amylase of silkworms living under unfavourable conditions.** K. YAMAFUJI (Biochem. Z., 1936, 287, 23—25).—The amylase contents of the blood and digestive juices of silkworms kept for a time under unfavourable conditions of aeration and moisture decrease considerably without obvious change in the appearance of the worms and do not regain their original vals. when the worms are replaced under favourable conditions. The amylase contents of the blood and juices of their offspring are also subnormal. P. W. C.

**Action of the lysin of pneumococcus on certain tissue-polysaccharides.** K. MEYER, R. DUBOS, and E. M. SMYTH (Proc. Soc. Exp. Biol. Med., 1936, 34, 816—818).—The same enzyme from pneumococci is capable of hydrolysing the carbohydrate complex (acetylglucosamine-glycuronic acid) from bovine vitreous humour or human umbilical cord, and heat-killed pneumococci. The optimum  $p_H$  is 5—6 and the enzyme is reversibly inactivated by I. P. G. M.

**Enzymic fission of difficultly hydrolysable glucoside of senna leaves.** E. TRIENDL (Arch. exp. Path. Pharm., 1936, 182, 527—532).—The glucoside (I) (Straub and Gebhardt, this vol., 1021) is hydrolysed (with formation of emodin; optimum  $p_H$  5.0) by mucous membrane of large and small intestine and by liver-tissue of dogs and cats, bitter almond preps., and emulsin. (I) is therefore a

$\beta$ -glucoside. With animal enzyme preps., enzymic oxidation of intermediary anthranol to anthraquinone occurs.  
F. O. H.

**Relations between vitamin-C and enzymic fission of carbohydrates.** I. R. WEIDENHAGEN and P. LU. II. R. WEIDENHAGEN (Z. Wirts. Zuckerind., 1936, 86, 240—253, 482—494).—I. Ascorbic acid (I) in 0.005M concn. reduced by 60—80% the rate of hydrolysis of sucrose by  $\beta$ -*h*-fructosidase [invertase (II), from yeast] in solutions buffered at  $p_H$  4.7 and 6.9, and its effect was detectable at 0.0001M. Even at 0.005M, however, the inhibition was entirely annulled by the presence of cysteine ( $10^{-3}M$ ), glutathione (III) (0.0001M), certain other S compounds or  $NH_2$ -acids at higher concn., or even by citric acid or  $H_2C_2O_4$  (0.005M). The opposite actions of (I) and (III) suggest a possible means by which (II) action may be controlled in plant life.

II. (I) produces inhibitory effects equal to or > those observed with invertase on  $\beta$ -glucosidase (highly purified emulsin from bitter almonds) and on the amylases of pancreas, wheat, barley, and malt. The amylases were purified by tannin pptn., followed by pptn. by  $COMe_2$ . In all cases (III) at the same equiv. concn. as (I) partly or entirely prevented the inhibitory action of (I).  
J. H. L.

**Separation of  $\beta$ -*h*-fructosidase [invertase] from yeast autolysates.** R. WEIDENHAGEN [with A. RENNER] (Z. Wirts. Zuckerind., 1936, 86, 473—481).—If a slightly acid yeast autolysate is adjusted to  $p_H$  8 with  $Sr(OH)_2$  the ppt. formed contains the whole of the invertase present; if  $Ca(OH)_2$  or  $Ba(OH)_2$  is used pptn. is not complete. The invertase may be dissolved from the washed ppt. by means of  $NH_4H_2PO_4$  or  $Na_2SO_4$ . Practical details of the method are given.  
J. H. L.

**Changes in the curve of enzymic hydrolysis of sucrose by the action of heat on the enzyme.** A. CHAUDIN (Bull. Soc. Chim. biol., 1936, 18, 1467—1470).—Invertase heated for 3 hr. at 55° hydrolyses sucrose less rapidly, but at the same time the angular point of the reaction curve is displaced so that the amount of enzyme appears to have increased. A similar effect has been observed with alkali, EtOH, and MeCHO.  
A. L.

**Lacto-mannitic enzymes. III. Products of fermentation of glucose.** V. BOLCATO (Annali Chim. Appl., 1936, 26, 356—361; cf. this vol., 638).—The enzymes which produce mannitol from fructose produce only lactic acid (I), EtOH,  $CO_2$ , and a little AcOH from glucose. The productions of (I) and EtOH are independent, and the ratio (I)/EtOH is not const. The mechanisms of the fermentation of glucose and fructose are compared.  
L. A. O'N.

**Recent researches on cell-free alcoholic fermentation.** O. MEYERHOF (Naturwiss., 1936, 24, 689—692).—A lecture.

**Pasteur and Meyerhof's reaction.** C. FRISCH and R. WILLHEIM (Biochem. Z., 1936, 287, 203—205).—Glycolysis in muscle extract is diminished by Warburg's respiratory enzyme but increased by lactoflavin, which also partly counteracts the inhibition caused by benzoquinone.  
W. McC.

**Role of the adenylic acid system and of cozymase in alcoholic fermentation.** P. OHLMEYER (Biochem. Z., 1936, 287, 212—225).—Although purified cozymase (I) and the adenylic acid (II) system do not differ as regards their effects on liberation of  $PO_4'''$  from phosphopyruvic acid (III) and transfer of  $PO_4'''$  to glucose (IV) from (III), (I) cannot be replaced by (II) in the conversion of hexose diphosphate [with or without (IV)] in presence of NaF into phosphoglyceric and glycerophosphoric acid and in the interaction of (IV) and MeCHO in presence of inorg.  $PO_4'''$ . Hence in the system (III) + (IV) fermentation ceases when the  $CO_2$  equiv. of (III) has been liberated when (II) replaces (I) but continues if (I) is not so replaced.  
W. McC.

**Inhibition of glycolysis by heavy metals and reversal of this inhibition.** T. WAGNER-JAUREGG and H. W. RZEPPA (Z. physiol. Chem., 1936, 243, 166—172; cf. this vol., 895).—The amount of  $CuSO_4$  required to inhibit glycolysis in muscle extract from *Rana esculenta* is 5—10 times that necessary with extract from *R. temporaria* and no inhibition is produced in rabbit muscle extract by 0.00017M- $CuSO_4$ . Pure and impure cozymase (I) and Warburg's co-enzyme (II) (but not KCN and ascorbic acid) and, to a much smaller extent, cysteine and glutathione reverse the inhibition whilst muscle-adenylic acid acts indefinitely. (I) and (II), which reactivate in the mol. ratio of >5 to 1 of metal, probably act by producing complexes or difficultly sol. salts with Cu.  $Fe^{II}$  inhibits  $\ll$  does Cu whilst  $Fe^{III}$ , Zn, and Cd have little or no effect and Mn stimulates glycolysis.  
W. McC.

**Inactivation of cozymase in an apozymase system poisoned with fluoride.** A. LENNERSTRAND (Biochem. Z., 1936, 287, 172—188; cf. this vol., 380).—In the system apozymase + cozymase (I) + glucose (II) + hexose diphosphate (III) +  $PO_4'''$  buffer phosphorylation and  $O_2$  consumption occur to a small extent in presence of NaF but soon cease. Methylene-blue added after the cessation is decolorised only very slowly. Pyocyanine (IV) increases phosphorylation and  $O_2$  consumption to an extent which diminishes to zero as the interval of time which elapses before the addition increases. The duration of  $O_2$  consumption and phosphorylation  $\propto$  the concn. of (III). After  $O_2$  consumption and phosphorylation have ceased they are re-started by addition of (I) [but not by that of (III), muscle-adenylic acid (V), adenosinetriphosphoric acid (VI), or Warburg's co-enzyme]; the  $O_2$  consumption, within limits, then  $\propto$  the amount of (I) added. If NaF + (IV) + (II) are added to the system vigorous  $O_2$  consumption occurs even if liberation of  $CO_2$  has almost ceased. These findings indicate that cessation of  $O_2$  consumption and phosphorylation are due to the inhibitory action of NaF on some mechanism which protects (I). The extent of inhibition is measured by the effect of (IV). In the enzyme system of yeast (I) alone can act as  $PO_4'''$  carrier whilst (V) accelerates the process but cannot act alone. During fermentation (I) continuously phosphorylated by phosphopyruvic acid (VII) transfers  $PO_4'''$  directly or by way of (V) and (VI) to

(II). NaF prevents dephosphorylation of (VII) and hence (I) cannot act. W. McC.

**Cozymase and dihydrocozymase in living cells.** E. ADLER and H. VON EULER (Svensk Kem. Tidsskr., 1936, 48, 221—226; cf. this vol., 246).—Cozymase (I) and dihydrocozymase (II) exist in the living cell as intermediates in fermentation and muscular activity enzyme systems. The stability of (I) to acids and of (II) to alkalis enables the (I)/(II) ratio to be determined. M. H. M. A.

**Zymohexase. III. Determination [of activity].** E. BAUER (Z. physiol. Chem., 1936, 243, 202—206; cf. this vol., 1299).—The activity of zymohexase (I) (with and without HCN activation) is max. at  $p_H$  9.5—10.0 but most stable at  $p_H$  7—8. At  $p_H > 10$  irreversible inactivation occurs. The stability decreases more rapidly in the acid than in the alkaline zone. The activity is independent of substrate [hexose diphosphate (II)] concn. Until the amount of P converted into alkali-hydrolysable form reaches 0.003%, the amount of (II) decomposed  $\propto$  the (I) concn. The unit of (I) is defined as the amount which converts 0.01 mg. of P into alkali-hydrolysable form in 1 hr.  $Fe^{III}$  activates (I) at  $p_H$  9.1 but inactivates it in slightly acid media. (II) forms with Fe a very stable complex salt which possibly is partly responsible for the activating effect of Fe. The affinities of (I) for (II) and this complex are probably different. W. McC.

**Choline esterase.** H. KWIATOWSKI (Fermentforsch., 1936, 15, 138—151).—Choline esterase (I) was detected in lymph, bile, and skin dialysate. (I) is not adsorbed by bolus alba and animal C, is not destroyed by X-rays, and is inhibited by pituglandol, padutin, NaF, and prostigmine (II), but not by histamine. The synthesis of acetylcholine from choline and NaOAc in fluids containing (I) depends on the amount of (I) present and is inhibited by phsostigmine, (II), and NaF. E. A. H. R.

**Action of the stereoisomerides of leucylglycylglycine on pancreas- and liver-esterase.** W. GERTLER (Fermentforsch., 1936, 15, 171—176).—All stereoisomerides of leucylglycylglycine (I), especially the *l*-form, strongly activate the hydrolysis of tributyrin (II) by pancreatic lipase. The effect is less marked with  $PrCO_2Me$  (III). (I) has no effect on the hydrolysis of (II) and (III) by liver-esterase, or on the enzymic hydrolysis of acetylcholine. E. A. H. R.

**In vitro hydrolysis of fats by lipase and bile salts.** J. E. DAVIS (Proc. Soc. Exp. Biol. Med., 1936, 34, 772—775).—A method is evolved for *in vitro* hydrolysis of fats by lipase and bile salts, by means of which equilibrium is reached in 24 hr. at 24% hydrolysis. P. G. M.

**Enzymic hydrolysis of nucleotides and nucleosides. I. Hydrolysis of purine ribonucleotides.** H. ISHIKAWA and Y. KOMITA (J. Biochem. Japan, 1936, 23, 351—363; cf. this vol., 433).—Dog's pancreas preps. hydrolyse guanylic (I) and xanthylic acid to give ribose phosphate (II) (optimum  $p_H$  7.5), small amounts of  $NH_3$  being liberated from (I) when crude enzyme preps. are used. Dog's pancreas

also contains a nucleosidase. Cat's pancreas yields (II) from nucleotides and also contains nucleosidase and deaminase which are absent from ox and pig's pancreas. Nucleotidase and nucleosidase occur in rabbit's liver, kidney, muscle, and small intestine. Nucleotides are hydrolysed both by primary dephosphorylation and by splitting of the pentose linking followed by hydrolysis of (II). F. O. H.

**Tyrosinase. II. Action of potato-tyrosinase on phenols and the influence of amino-compounds on the tyrosinase system.** F. NOBUTANI (J. Biochem. Japan, 1936, 23, 455—485).—Tyrosinase (I) produces pigments only from those phenolic substances which yield *o*-quinones on oxidation. The  $O_2$  uptake by *p*-cresol or pyrocatechol in presence of (I) is 1 atom  $>$  that corresponding with formation of *o*-benzoquinone.  $NH_2$ -acids accelerate the action of (I) but do not affect the  $O_2$  consumption, whilst  $NH_2OH$  accelerates the action but depresses  $O_2$  consumption. The mechanism of these phenomena is discussed. F. O. H.

**Polypeptidases excreted in the urine of health and disease.** P. STEINBRÜCK (Fermentforsch., 1936, 15, 121—133). E. A. H. R.

**Polypeptidases of blood-serum and -plasma.** R. ABDERHALDEN (Fermentforsch., 1936, 15, 157—170).—Protection of the  $CO_2H$  of polypeptides inhibits the action of the carboxypolypeptidase in trypsin (I), for it hydrolyses neither *dl*-leucylglycyl-methylamine (II), m.p. 76—78°, nor *dl*-leucylglycyl-glycylbenzylamine (III), m.p. 130—131°. (II) and (III) are hydrolysed by erepsin (IV) and serum to a greater extent than the corresponding polypeptides, perhaps because of a greater ease of attachment of the  $NH_2$  to the enzyme surface when the  $CO_2H$  is blocked. *dl*-(*N*)-Benzyl-leucylglycylbenzylamine, m.p. 70—71°, is not hydrolysed by (I), (IV), or serum, and can be recovered unchanged 10 days after injection into a rabbit. The aminopolypeptidase content of foetal blood is the same as, but the dipeptidase content is  $<$ , that of the mother. E. A. H. R.

**Fibrinolysis. V.** M. ROSENMANN (Biochem. Z., 1936, 287, 26—32).—A substance is present in serum which is inactivated by heating for  $\frac{1}{2}$  hr. at 50° and is identical with thrombolysin (I) (A., 1922, i, 596). The  $p_H$  optimum for fibrinolysis by autolysate-(I) is between 7.8 and 8.4 and for serum-(I) between 8 and 8.4, whilst the material is active over the range  $p_H$  5.8—10. The  $p_H$  optimum is not displaced by addition of thromboligin. P. W. C.

**Autodigestion. VI. Digestion of living tissues by trypsin.** H. NECHELES, P. LEVITSKY, and M. MASKIN (Proc. Soc. Exp. Biol. Med., 1936, 34, 768—772).—Tryptic digestion of living frogs' legs can take place following immersion in HCl or pepsin-HCl. P. G. M.

**Influence of high temperatures on the trypsin of warm- and cold-blooded vertebrates.** P. A. KORSCHUJEFF (Fermentforsch., 1936, 15, 152—156).—The higher is the body-temp. of a vertebrate, the greater is the thermostability of its trypsin. E. A. H. R.

**Enzymic digestion of lactalbumin and caseinogen *in vitro*.** M. C. KIK (Proc. Soc. Exp. Biol. Med., 1936, **34**, 194—196).—Lactalbumin is less readily digested *in vitro* by trypsin and erepsin than is caseinogen. W. McC.

**Determination of antitrypsin.** K. L. BURDON and C. LAFFERTY (Proc. Soc. Exp. Biol. Med., 1936, **34**, 787—790).—Opaque photographic film is used for titration of antitrypsin; the amount of trypsin required to produce complete transparency of the film is determined. P. G. M.

**Enzymes of snake venom. I. Their action on hæmoglobin and on protein solutions of different  $p_H$ .** B. N. GHOSH (J. Indian Chem. Soc., 1936, **13**, 450—455).—Proteolytic activity of cobra venom to gelatin and ovalbumin is a max. at  $p_H$  7.8—8.0 and to casein at  $p_H$  6.6. The protease of this venom thus resembles trypsin. This venom and that of Russell's viper cause oxidation of hæmoglobin to methæmoglobin. R. S. C.

**Tissue proteinases (cathepsin) in protein-free and low-protein feeding.** B. GOLDSTEIN and M. GINZBURG (Ukrain. Biochem. J., 1936, **9**, 341—354).—Protein-starved and gelatin-fed rabbits show an increase of cathepsin (I) concn. in the kidney and, more especially, in the liver, the difference between  $H_2S$ -non-activated and  $H_2S$ -activated (I) being also raised. Predominance of protein synthesis in the organ appears to be accompanied by strong activation of (I) by  $\cdot SH$ . Protein synthesis is increased in the livers of rabbits on restricted protein diets. F. A. A.

**Intracellular proteinases. XVIII. Effect of co-enzyme and cozymase on proteinases reversibly inactivated by heavy metals.** E. MASCHMANN and E. HELMERT (Z. physiol. Chem., 1936, **243**, 207—208; cf. A., 1935, 1538).—The inactivating effect of Cu on the degradation of gelatin by papain (I) and cathepsin (II) is not reversed by addition of Warburg's co-enzyme (III) or Euler's cozymase (IV). The action of (I) but not that of (II) is appreciably restricted by (III) and (IV). W. McC.

**Proteolytic enzymes. XI. Specificity of papain peptidase I.** M. BERGMANN, L. ZERVAS, and J. S. FRUTON (J. Biol. Chem., 1936, **115**, 593—611; cf. this vol., 1152).—The hydrolysis by peptidase I of compounds of the type  $NHR''\cdot CO\cdot CHR'\cdot NH\cdot CO\cdot R$  ( $R=Ph$  or  $O\cdot CH_2Ph$ ) was investigated. Hippurylamide (I) ( $R=Ph$ ,  $R'=H$ ,  $R''=H$ ) is readily hydrolysed whilst derivatives ( $R''=Me$ , *isoamyl*, or *Ph*) under the same conditions were only slightly hydrolysed. Carbobenzoyloxyglycylglycine (II) and -di- and -tri-glycylglycine are hydrolysed with increasing velocity as  $R''$  increases in length. Hydrolysis of (I), hippurymethylamide, and (II) indicates an inhibitory influence of  $Me$  but not  $CO_2H$ . *Benzoylglycylglycine piperidide*, m.p. 134°, is hydrolysed more rapidly than is (II). The splitting of carbobenzoyloxyglutamyl- $\alpha$ -amide is  $>$  that of derivatives where  $R''=isoamyl$  or, to a greater extent,  $R''=Me$ . In order to demonstrate the marked effect of slight structural changes on the rate of hydrolysis, the hydrolysis of, amongst others, the

following compounds was studied: *benzoyl-l-leucyl-l-leucylglycine*, m.p. 161°, *carbobenzoyloxy-l-glutamylglycylglycine*, m.p. 142° (*Et* ester, m.p. 139—140°), *benzoyl-l-lysineamide* (III), m.p. 187° [*d-isomeride* (IV), m.p. 187°]. The linking ' is more readily attacked than ". The peptidase hydrolyses a variety of peptide linkings with widely different velocities. The fission of free polypeptides by papain is due to peptidase I. (III) but not (IV) is hydrolysed. The antipodal specificity of peptidase I is discussed (cf. A., 1935, 1416). The following compounds were prepared: *l-leucyl-l-leucylglycine* (carbobenzoyloxy-methyl ester, m.p. 108°), *carbobenzoyloxypiperidide*, m.p. 78°, *hippuryl-anilide*, m.p. 214°, and *isoamylamide*, m.p. 98°, *carbobenzoyloxy-l-glutamyl-methylamide*, m.p. 178°, and *isoamylamide*, m.p. 135°.

F. O. H.

**Proteases and proteolytic processes in muscle tissue. III. Activity of muscle proteases in B- and C-avitaminosis.** S. V. FOMIN and N. M. ROMANTSCHUK (Ukrain. Biochem. J., 1936, **9**, 355—368).—The protease activity on caseinogen of muscle extracts from B-avitaminotic pigeons or C-avitaminotic guinea-pigs is  $<$  that of extracts from normal animals. F. A. A.

**Influence of phloridzin on renal phosphatase *in vitro*.** A. LAMBRECHTS (Compt. rend. Soc. Biol., 1936, **123**, 311—313).—There is no parallelism between the diabetogenic and inhibitory actions.

H. G. R.

**Phosphatase of human milk.** K. V. GIRI (Z. physiol. Chem., 1936, **243**, 57—62).—Human milk contains phosphatases exhibiting optimal activity at  $p_H$  9.2 and 5.1, respectively, with Na glycerophosphate (I) as substrate. The first is activated by  $Mg^{++}$ ; the second is not. Na hexose diphosphate (II) is more readily hydrolysed by the phosphatases than is (I), and  $Na_4P_2O_7$  is much more readily hydrolysed than are (I) and (II). The amount of the phosphatases in the milk 3 days *post partum* is that in the milk of later stages of lactation and they are activated to a greater extent by  $Mg^{++}$ . W. McC.

**Fermentation enzymes. VI. Dephosphorylating enzymes of yeast.** A. SCHAFFNER and F. KRUMEY (Z. physiol. Chem., 1936, **243**, 149—165).—Although the action of  $\alpha$ -glycerophosphatase, phosphatase from top yeast, and phosphatases exhibiting optimal effects at  $p_H$  9 and 7, respectively, is inhibited by  $AsO_4'''$  and that of pyrophosphatase is unaffected, the dephosphorylation of hexose diphosphate (I) by crude yeast maceration juice is very greatly accelerated. Since dephosphorylation of phosphopyruvic acid (II) by the juice is greatly accelerated by added adenylic acid (III), it is possible that an early stage in fermentation consists in interaction of (II) and (III) to give adenosinetriphosphoric acid (IV) and  $AcCO_2H$ .  $AsO_4'''$  accelerates the dephosphorylation of (IV) by the juice. The phosphatase exhibiting optimal action at  $p_H$  7 does not attack (IV).  $AsO_4'''$  inhibits phosphorylation by (I) and (IV). If sufficient org.  $PO_4'''$  is present fermentation can proceed without the consumption of inorg.  $PO_4'''$ , (II) from (I) reacting as described and (IV) with glucose yield-

ing (I) and (III) so that a closed system, capable of acting for a long time, is formed. W. McC.

**Glucosidases of *Schizosaccharomyces*.** E. HOFMANN (Biochem. Z., 1936, 287, 271—275; cf. this vol., 1024).—*S. octosporus*, *S. Pombe*, and *S. mellacci* contain maltase and  $\alpha$ -methylglucosidase both exhibiting optimal activity at  $p_H$  4.5. Invertase is also present and hydrolyses raffinose to fructose and melibiose (I) but does not attack (I). W. McC.

**Fermentation of phosphogluconic acid.** F. LIPMANN (Nature, 1936, 138, 588—589).—Curves for the aerobic and anaerobic fermentation of phosphogluconic acid (in yeast macerate) show that in absence of  $O_2$  the formation of  $CO_2$  is slow. Behaviour in presence of  $CH_3Br \cdot CO_2$  (I) suggests that a primary oxidation and decarboxylation, unaffected by (I), is followed by a reaction which may be of an enzymic nature. Fluoride inhibits  $O_2$  absorption and  $CO_2$  formation more strongly than (I). L. S. T.

**Importance of "pantothenic acid" in fermentation, respiration, and glycogen storage.** R. J. WILLIAMS, W. A. MOSHER, and E. ROHRMAN (Biochem. J., 1936, 30, 2036—2039).—Yeast having an extremely low pantothenic acid (I) content (2% of the normal amount) is almost lacking in fermenting power but fermentation is increased on adding a minute amount of (I). Aerobic respiration is also very low and is only slightly increased when (I) is added after the yeast is grown. Yeast grown with a good supply of (I) respire much more rapidly than does the deficient yeast. Most samples of maltose (II) contain (I), which is removed completely only by electrolytic transport. The promotion of glycogen storage in yeast by (II) (McAnally and MacLean, A., 1935, 1164) is due to the (I) content. (I) thus plays a fundamental rôle in carbohydrate anabolism and catabolism whether the latter is aerobic or anaerobic. P. W. C.

**Effect of  $\alpha$ -keto-acids other than pyruvic acid on the synthesis of amino-acids by yeast.** C. FROMAGEOT and G. MINARD (Bull. Soc. Chim. biol., 1936, 18, 1454—1466).— $\alpha$ -Keto-acids (e.g.,  $COPr^a \cdot CO_2H$  and  $CHMeEt \cdot CO \cdot CO_2H$ ) capable of decarboxylation by decarboxylase, when added to sucrose solutions undergoing fermentation by yeast, are converted into alanine (I). Addition of  $COBu^v \cdot CO_2H$  does not increase the yield of (I). A. L.

**Thermal analysis and action on fermentation of mixtures of antiseptics.** A. MOSSINI (Boll. Chim. farm., 1936, 75, 493—494).—Mixtures of Me or Pr *p*-hydroxybenzoate with camphor (I) have eutectic points at 59.9° [70% of (I)] and 32° [60% of (I)], respectively. The respective actions on yeast fermentation, however, are additive with respect to those of the components. F. O. H.

**Increase of diamagnetic susceptibility on the death of living cells.** E. BAUER and A. RASKIN (Nature, 1936, 138, 801).—The increase observed in the case of yeast and *B. coli* and *B. proteus* supports the theory that the lack of equilibrium in living systems is due to an excited state of protein mols. of the protoplasm. Denaturation of native protein does not affect magnetic susceptibility. L. S. T.

**Strains of yeast which produce alcoholic fermentation at low temperatures.** B. PORCHET (Mitt. Lebensm. Hyg., 1936, 27, 42—45).—Yeasts responsible for the spontaneous fermentation of grape musts and apple juice at  $-3^\circ$  to  $0^\circ$  are indistinguishable morphologically from other forms of *S. ellipsoideus*; they form white colonies with irregular edges and a central crater on gelatin at room temp., without producing liquefaction. They develop a fine bouquet and are suitable for wine and cider production, being superior to ordinary yeasts in fermentations at  $6^\circ$ . J. G.

**Gum and glycogen of yeast.** F. STOCKHAUSEN and K. SILBEREISEN (Biochem. Z., 1936, 287, 276—286).—The amounts of the gum in brewer's, wine, and baker's yeast are respectively 4—6, 7.5—8.5, and up to 13%. The glycogen and gum of yeast exist as such in the cells and are not produced by the action of the hot 65% KOH solution used in extraction. W. McC.

**Determination of hexoses by fermentation.**—See this vol., 1490.

**Formation of oxalic and citric acids by fungi.** V. S. BUTKEVITSCH (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 427—430).—Polemical against Chrzaszcz *et al.* (A., 1935, 254; this vol., 1026, 1027). E. A. H. R.

**Pharmacodynamic action of iron in general metabolism.** O. KAUFFMANN-COSLA and R. BRÜLL (Bull. Soc. Chim. biol., 1936, 18, 1493—1502).—The monose content of *Aspergillus niger* grown in media containing no Fe is  $>$  normal. The cellulose content is normal, but the lipin content  $<$  normal. Fe is therefore necessary for normal carbohydrate and lipin synthesis. A. L.

**Assimilation of nitrites by fungi. III.** Y. WANG (J. Agric. Chem. Soc. Japan, 1936, 12, 877—884).—Assimilation of  $NO_2^- \cdot N$  by various species of *Aspergillus* does not depend on the previous mode of culture of the fungus but is largely conditioned by the nature of the sources of C. W. O. K.

**Production of acids from sugar by *Aspergillus niger*. VII. Importance of nitrogen source for citric acid production.** K. BERNHAUER and A. IGLAUER (Biochem. Z., 1936, 287, 153—166; cf. A., 1936, 1026).—Citric acid (I) production by *A. niger* is optimal when the N concn. of the medium is 0.07—0.875%. The rate of (I) production and the amount of (I) produced vary with the N source employed, the highest rate and yield (80—90%) being obtained with  $NH_4NO_3$  and  $Mg(NO_3)_2$  and sugar concn. 17.5—20%. (I) production with  $NH_4NO_3$  as N source is very greatly accelerated by addition of  $MgCl_2$ , especially when the sugar concn. is high. The yield and rate of production of (I) are affected by the purity of the sugar used. W. McC.

**Production of citric acid from lactic acid and from alcohol.** T. CHRZASZCZ and K. LEONHARD (Biochem. J., 1936, 30, 1947—1952).—On media containing  $CaCO_3$  *Botrytis cinerea* partially converted Ca and  $NH_4$  lactates into citric acid (I),  $H_2C_2O_4$  (II), and  $CO_2$  with small amounts of malic acid (III), fumaric acid (IV),  $AcOH$ ,  $EtCO_2H$  (V),  $AcCO_2H$

(VI), and MeCHO. Without  $\text{CaCO}_3$ , the utilisation of  $\text{NH}_4$  lactate was greater but (II) was not obtained. On a medium containing  $\text{CaCO}_3$ , EtOH was utilised yielding (I), (III),  $\text{HCO}_2\text{H}$ , AcOH, (II), and  $\text{CO}_2$ . Lactic acid (VII) is first converted into (VI) which is decarboxylated to MeCHO. This is either oxidised to AcOH or with a mol. of (VII) undergoes dismutation into (V) + AcOH. The AcOH formed is converted *via* succinic acid, (IV), and (III) into (I) or is oxidised *via*  $\text{OH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ , (II), and  $\text{HCO}_2\text{H}$  to  $\text{CO}_2 + \text{H}_2\text{O}$ . In older cultures the (I) formed possibly also undergoes decomp. P. W. C.

**Production of acids by *Rhizopus*.** I. Production of malic acid in fumaric acid fermentation. K. BERNHAUER and H. THOLE (Biochem. Z., 1936, 287, 167—171).—The variation in the yield of fumaric acid (I) produced from glucose in presence of  $\text{CaCO}_3$  by strains of *Rhizopus* is due to the conversion of (I) into malic acid, the amount of which continues to increase while that of (I) after reaching a max. is decreasing. W. McC.

Low concentrations of deuterium oxide and the growth of marine diatoms. D. L. FOX, E. E. CURP, and G. F. McEWEN (Proc. Soc. Exp. Biol. Med., 1936, 34, 575—581).—The growth rate of *Nitzschia bilobata* shows a tendency to lag in dil.  $\text{D}_2\text{O}$ .

P. G. M.

**Detection of hormones in unicellular animals.** I. Choline and acetylcholine in *Paramecium*. II. Adrenaline in *Paramecium*. G. BAYER and T. WENSE (Pflüger's Arch., 1936, 237, 417—422, 651—654).—I. Choline was demonstrated in *Paramecium* by the effect of a Ringer extract of the organism on the eserinated dorsal muscles of the leech, the effect being considerably increased on acetylation. The presence of acetylcholine (I) in the original extract was also shown. *Paramecium* contains less (I) at low temp. at which the esterase is more active.

II. Adrenaline was demonstrated in *Paramecium*.

M. A. B.

**Isolation of *Glaucoma ficaria*, Kahl, in bacteria-free cultures: growth in relation to the  $p_{\text{H}}$  of the medium.** D. F. JOHNSON (Arch. Protistenk., 1935, 86, 262—277).—The growth range of *G. ficaria* is  $p_{\text{H}}$  4.9—9.5 and that of *G. piriformis*, 4.0—8.9. The latter has the lower  $p_{\text{H}}$  optimum.

A. G. P.

**Physiology of euglenoid flagellates.** V. Effect of certain carbohydrates on growth of *Euglena gracilis*, Klebs. VI. Effects of temperature and of acetate on *E. gracilis* cultures in the dark. VII. Effects of salts of certain organic acids on growth of *E. gracilis*. T. L. JAHN (Arch. Protistenk., 1935, 86, 238—250, 251—257, 258—262).—V. Transference of *E. gracilis* from an inorg. medium to one to which carbohydrates are added may result in encystment or modification of the rate of division. Effects vary with the carbohydrate used and probably also with the physiological condition of the stock, with temp., light intensity, and  $p_{\text{H}}$ .

VI. Addition of NaOAc to peptone media increased the rate of division and raised the optimum growth temp.

VII. In daylight the rate of division was accelerated by addition to media of  $\text{PrCO}_2\text{Na}$  (I), NaOAc,  $\text{Na}_2\text{C}_2\text{O}_4$ , and Na lactate (II) (in descending order), unaffected by NaCl,  $\text{HCO}_2\text{Na}$ , Na tartrate and citrate, and retarded by Na succinate (III). In darkness, the order of acceleration was (I) > NaOAc > (II) > (III) and  $\text{HCO}_2\text{Na}$  caused some deceleration. A. G. P.

**Oxidation-reduction potential of protozoan cultures.** II. Reduction potential of cultures of *Chilomonas paramecium*. T. L. JAHN (Arch. Protistenk., 1935, 86, 225—237; cf. A., 1934, 329).—Changes in the  $E_h$  of cultures in different media are determined by means of special apparatus described. These changes are largely attributable to removal of  $\text{O}_2$  from the medium during growth although the possibility of the production of reducing substances by the organism is not eliminated. Variations in  $E_h$  may be a causative factor in allelocatalysis.

A. G. P.

**Utilisation of sugars by *Leishmania tropica*.** A. DuBOIS (Compt. rend. Soc. Biol., 1936, 123, 141—144).—Carbohydrates most readily utilised include glucose, fructose, mannose, galactose, sucrose, inulin, and glycerol.

H. G. R.

**Resistance of Leishman-Donovan bodies to various physical, chemical, and biological agents.** I. Physical agents. H. L. CHUNG (Chinese Med. J., 1936, 50, 1039—1050).—Leishman-Donovan bodies were tested for viability (by injection into hamsters) after various treatments. The bodies were resistant to X-rays, to temp. of 40—43° for 30 min., and to -25° for 48 hr., but succumbed to drying for 1½ hr.

G. H. B.

**Metabolism of bacteria in exhausted media and media containing vaccines.** A. DAMBOVICANU and H. ROTH (Compt. rend. Soc. Biol., 1936, 123, 61—63).—Cessation of growth of streptococci in a liquid medium is due to consumption of the sugar, no evidence being obtained of the production of inhibiting substances.

H. G. R.

**Physiology of *Rhizobium*.** VI. Accessory factors. D. W. THORNE and R. H. WALKER (Soil Sci., 1936, 42, 231—240; cf. this vol., 114).—Small quantities of Fe added to a  $\text{NO}_3^-$ -sucrose medium increased the growth of *R. trifolii* and *R. meliloti*,  $\text{Fe}^{+++}$  being more active than  $\text{Fe}^{++}$ . Repeated subculturing in mineral salt-sucrose media with  $\text{KNO}_3$  as N source led to growth failure, but with  $\text{NH}_4\text{Cl}$  or asparagine full activity was retained. Growth and  $\text{O}_2$  consumption in highly purified media may be improved by addition of cysteine or thioglycollic acid. The organisms do not require any complex or unidentified substances for growth, although many substances have stimulatory effects.

A. G. P.

**Association of characters among dissociates from *Staphylococcus aureus*.** M. DOUDOROFF (Proc. Soc. Exp. Biol. Med., 1936, 34, 216—217).—In the dissociates relatively high power to produce haemolysin, to liquefy gelatin, and to produce fibrinolysin are each associated with relatively low production of orange pigment and relatively high production of white pigment. The violet reaction and the

production of coagulase apparently remain const. despite variations in the amount of pigment produced.

W. McC.

Relation of so-called *Streptococcus apis* to certain lactic acid streptococci. J. G. DAVIS and H. L. A. TARR (Nature, 1936, 138, 763).—The two kinds of *S. apis* previously reported (this vol., 763) are morphologically, culturally, and biochemically indistinguishable from *S. glycerinaceus* and *S. liquefaciens*.

L. S. T.

Enzymic racemisation of optically active lactic acid. E. L. TATUM, W. H. PETERSON, and E. B. FRED (Biochem. J., 1936, 30, 1892—1897).—Associated growth of *Strep. lactis* or *Lactobacillus delbrückii* with the  $\text{PrCO}_2\text{H}$  organisms *Cl. acetobutylicum* or *Cl. butylicum* leads to the formation of inactive lactic acid (I) due to the racemising action of the latter bacteria. In the absence of lactic acid bacteria, both  $\text{PrCO}_2\text{H}$  organisms partly ferment active (I) and racemise the remainder. Cultures of these  $\text{PrCO}_2\text{H}$  organisms convert either *d*- or *l*-(I) quantitatively into the *dl*-acid in presence of antiseptics. The racemising system consists of extracellular heat-labile (10 min. at  $87^\circ$ ) and intracellular heat-stable components. Neither cell suspensions nor cell-free media of *Cl. butylicum* can racemise active (I) but the two are effective in combination.

P. W. C.

Butyl alcohol and acetone fermentations. II. Intermediate products of the butyl alcohol-acetone fermentation. K. BERNHAUER, A. IGLAUER, W. GROAG, and R. KÖRTIG (Biochem. Z., 1936, 287, 61—64).—Further experiments (cf. A., 1935, 1541) on the intermediate products of this fermentation are described. When the fermentations are carried out in presence of  $\text{CaCO}_3$ ,  $\text{PrCHO}$  gives 80% yields of  $\text{Bu}^\circ\text{OH}$ , whilst crotonic acid gives 66—80% and  $\text{AcCO}_2\text{H}$  and lactic acid 70% yields of  $\text{AcOH}$ . In each case considerably more Bu products ( $\text{PrCO}_2\text{H}$ ,  $\text{BuOH}$ ) and correspondingly less  $\text{COMe}_2$  products ( $\text{COMe}_2$ ,  $\text{AcOH}$ ,  $\text{EtOH}$ ) are obtained in the absence than in the presence of  $\text{CaCO}_3$ .

P. W. C.

Metabolism of strict anaerobes (genus *Clostridium*). V. Coupled reactions between pairs of amino-acids induced by *Cl. sporogenes*. D. D. WOODS (Biochem. J., 1936, 30, 1934—1946).—In the linked oxidation and reduction of pairs of  $\text{NH}_2$ -acids by washed cells of *Cl. sporogenes l*-cysteine (I) can act as a H donor and also is partly deaminated in the absence of other acids. Glycollic acid,  $\beta$ -alanine, and taurine are not attacked, whilst *d*-ornithine (II) and *d*-arginine (III) are both activated as H acceptors and partly deaminated in the absence of H donors. When (II) reacts with alanine, it accepts 2 H and undergoes reductive deamination to  $\delta$ -aminovaleric acid. Simple  $\text{NH}_2$ -acids (with the exception of glycine) appear to act only as H donors. When there is another substituent group in the chain in addition to the  $\alpha$ - $\text{NH}_2$ , the acids are broken down in the absence of other  $\text{NH}_2$ -acids. If this extra group is not  $\text{NH}_2$  [(I), serine] the substance also acts as a H donor but if it is or contains  $\text{NH}_2$  [(II), (III)] the substance also acts as a H acceptor (cf. A., 1935, 537, 664).

P. W. C.

Mechanism of oxidation processes. XLV. Anaerobic fermentation of fumaric acid. H. WIELAND, M. CRAWFORD, and H. WALCH. XLVI. Anaerobic fermentation of citric acid. R. SONDERHOFF and M. DEFFNER (Annalen, 1936, 525, 119—131, 132—138; cf. this vol., 893).—XLV. Cultures of bacteria occurring in certain impoverished yeasts, if < 24 hr. old, or yeasts containing them, change Na fumarate (I) anaerobically into  $(\cdot\text{CH}_2\cdot\text{CO}_2\text{H})_2$  (II) 0.5,  $\text{CO}_2$  0.7—0.75,  $\text{EtOH}$  0.1,  $\text{AcOH}$  0.4, and  $\text{HCO}_2\text{H}$  0.2 mol. The primary reaction is  $(\text{I}) + \text{H}_2\text{O} \rightarrow \text{malic acid (III)}$ ;  $(\text{III}) + (\text{I}) \rightarrow (\text{II}) + \text{CO}_2\text{H}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$  (IV);  $(\text{IV}) \rightarrow \text{CO}_2 + \text{AcCO}_2\text{H} \rightarrow \text{CO}_2 + \text{MeCHO}$ ;  $2\text{MeCHO} \rightarrow \text{EtOH} + \text{AcOH}$ . This is, however, complicated by the side reactions,  $(\text{IV}) \rightarrow \text{HCO}_2\text{H} + \text{CH}_2(\text{CO}_2\text{H})_2$ , and  $\text{AcCO}_2\text{H} + \text{H}_2\text{O} \rightarrow \text{AcOH} + \text{HCO}_2\text{H}$ , both of which are caused by the bacteria in neutral solution. This is confirmed by the rapid anaerobic production of (II),  $\text{CO}_2$ ,  $\text{EtOH}$ ,  $\text{AcOH}$ , and  $\text{HCO}_2\text{H}$  from *l*-(—)-(III) by the bacteria; *dl*-(III) is less quickly fermented, owing to the slower reaction of the *d*-form (which accumulates in the solution), and to its negative catalytic effect on fermentation of the *l*-form. The bacteria also ferment (IV) anaerobically, giving 25% of (II), the reaction being  $(\text{IV}) + \text{CHMe}(\text{OH})_2 \rightarrow \text{AcOH} + (\text{III})$ , etc. Formation of  $\text{HCO}_2\text{H}$  and  $\text{H}_2\text{C}_2\text{O}_4$  during various fermentations probably occurs by way of (IV). Sterile yeast does not act on (I).

XLVI. The anaerobic fermentation of citric acid (V) by yeast is due to bacteria (cf. A., 1933, 865; 1935, 1539), similar to those described above. The presence of aq. yeast extract is necessary for the production of much  $\text{H}_2$ . Sterile yeast, however, produces (V) and (II) from  $\text{Ba}(\text{OAc})_2$  and ferments (V) anaerobically.

R. S. C.

Aerobic breakdown of glucose by *Bact. suboxydans*. K. R. BUTLIN (Biochem. J., 1936, 30, 1870—1877).—Washed suspensions of *B. suboxydans* from maize wort-agar without  $\text{CaCO}_3$  are dirty white and oxidise glucose (I) at  $p_H$  5.5 but only to gluconic acid (II) and give no  $\text{CO}_2$ . Similar suspensions from wort-agar containing  $\text{CaCO}_3$  are pink, give a much larger and more rapid  $\text{O}_2$  uptake with (I), oxidising (I) to (II) and then probably to 5-ketogluconic acid; the  $\text{CO}_2$  evolved equals the  $\text{O}_2$  absorbed. No synthesis of hexose phosphates by suspensions or air-dried or  $\text{COMe}_2$  preps. of either type was detected but cultures obtained on media containing  $\text{CaCO}_3$  had a much greater capacity for hydrolysing Na hexose diphosphate than the corresponding preps. without  $\text{CaCO}_3$ . The modification in enzymic properties by  $\text{CaCO}_3$  is a temporary variation.

P. W. C.

Growth factors for bacteria. V. Vitamin- $B_{11}$ , a growth stimulant for propionic acid bacteria. E. L. TATUM, H. G. WOOD, and W. H. PETERSON (Biochem. J., 1936, 30, 1898—1904).—The stimulating action of protein hydrolysates on acid production by  $\text{EtCO}_2\text{H}$  bacteria is partly due to a factor which can be separated from unhydrolysed caseinogen, ovalbumin, yeast extract, and milk powder by extraction with  $\text{COMe}_2$  or  $\text{EtOH}$  and is active in a concn. of  $0.15 \times 10^{-6}$  g. per mol. The factor is most active in presence of  $\text{NH}_2$ -acids, and is not replaced by

inositol, panthothenic acid, ascorbic acid, hepato-flavin, nicotinamide, or indolylacetic acid, but is replaceable by  $0.5 \times 10^{-3}$  g. of cryst. vitamin- $B_1$  per 100 ml.

P. W. C.

Effect of sulphur compounds on the fermentation of glucose by propionic bacteria. P. CHAIX and C. FROMAGEOT (Bull. Soc. Chim. biol., 1936, 18, 1436—1453; cf. this vol., 760).—The max. stimulating action of S compounds on the fermenting activity of propionic bacteria is obtained with  $>0.1$  mg. of S per 5 c.c. and is dependent on  $p_H$ . Ascorbic acid, glycine, and alanine have no activating effect.

A. L.

Combined action of succinodehydrogenase and aspartase in *Bacterium coli*. M. MICHAELIS (Z. physiol. Chem., 1936, 243, I).—The no. of cu. mm. of  $H_2$  transferred from 1 mg. of dry *B. coli* to methylene-blue in 1 hr. at  $p_H$  7.6 is increased from 2.5 to 7.3 by addition of 0.1N-Na succinate (I) and to 10.0 by addition of (I) +  $M-(NH_4)_2SO_4$ . The acceleration occurs because the rate of production of fumarate (II) from (I) by succinodehydrogenase is  $<$  the rate of conversion of (II) +  $NH_3$  into aspartic acid by aspartase.

W. McC.

Fermentation of pyruvic acid by *colon-aerogenes* bacteria. M. MICKELSON, H. REYNOLDS, and C. H. WERKMAN (Proc. Soc. Exp. Biol. Med., 1936, 34, 748—750).—*Escherichia coli* and *Citrobacter freundii* decompose  $AcCO_2H$  by a similar mechanism,  $AcOH$  being largely produced along with lactic acid,  $HCO_2H$ ,  $CO_2$ , and  $H_2$ . *Aerobacter indologenes* can also reduce the  $AcOH$  to  $(\cdot CHMe \cdot OH)_2$ .

P. G. M.

Hydrogen donators for *B. prodigiosus*. D. BACH and J. LAMBERT (Compt. rend. Soc. Biol., 1936, 123, 358—361).—Of 128 org. substances examined 94 were donators.

H. G. R.

Biology of the *pullorum-gallinarum* group. Differentiation of types of *pullorum* by maltose fermentation. C. RODRIGUES and G. PACHECO (Compt. rend. Soc. Biol., 1936, 123, 438—440).—The maltose of normal serum, if used in the medium, will vitiate results.

H. G. R.

Hydrogen donators for Friedlander's pneumobacillus. D. BACH and J. LAMBERT (Compt. rend. Soc. Biol., 1936, 123, 361—364).—Of 125 substances examined 68 were active.

H. G. R.

Soluble specific substances of pneumococcus type III possessing properties distinct from SSS III. G. J. P. HORNUS and J. F. ENDERS (Proc. Soc. Exp. Biol. Med., 1936, 34, 102—104).—A carbohydrate, isolated from type III pneumococcus by a method which avoids the use as far as possible of strong acid, reacts with type III antipneumococcus serum but is different from the sol. sp. substance III of Heidelberger *et al.* (cf. A., 1926, 545).

W. O. K.

Ultrafiltration in the concentration and purification of pneumococcus specific polysaccharides. R. BROWN (Proc. Soc. Exp. Biol. Med., 1936, 34, 832—833).—A 16 hr. culture of pneumococcus (type VII) was centrifuged and the fluid ultrafiltered and washed on a 4% cellulose nitrate

membrane. 100-fold concn. resulted, with removal of 98.26% of the N. An initial concn. with aq.  $(NH_4)_2SO_4$ , prior to ultrafiltration, is also useful.

P. G. M.

Ash of bacteria (*Vibrio cholerae*). A. DAMBOVICANU and C. VASILESCO (Compt. rend. Soc. Biol., 1936, 123, 65—68).—The ash of *V. cholerae* is considerably influenced by the mineral content of the medium, particularly when the normal ash content of the organism is low.

H. G. R.

Ash of bacteria (*Vibrio cholerae*). C. BARBER (Compt. rend. Soc. Biol., 1936, 123, 64—65).—Species with a high ash content generally contain more K, Na, and P and less Ca than those with a low ash. In all species Ca is low compared with other bacteria.

H. G. R.

Carotenoids of purple bacteria. III. P. KARRER and U. SOLMISSEN (Helv. Chim. Acta, 1936, 19, 1019—1024; cf. this vol., 248, 340).—Further examination of the *Rhodovibrio* carotenoids shows that rhodopin contains probably 1 OH and 12 double linkings. In accordance with its position in the chromatogram rhodovibrin is a polyene alcohol. Rhodoviolasene,  $C_{42}H_{60}O_2$ , contains 2 OMe, 13 double linkings, and  $>1$  Pr<sup>2</sup>; it is probably  $OMe_2 \cdot CH \cdot C(OMe) \cdot CH \cdot CMe \cdot [CH \cdot CH \cdot CH \cdot CMe]_2 \cdot CH \cdot CH \cdot [CH \cdot CH \cdot CMe \cdot CH]_2 \cdot CH \cdot CH \cdot C(OMe) \cdot CH_2 \cdot CHBn^2 \cdot OMe$ . Rhodopurpurene is a hydrocarbon resembling lycopene spectroscopically, but its identity therewith is doubtful. The presence of  $\beta$ -carotene is occasionally observed. Flavorhodin is probably a hydrocarbon but certainly not a polyene with free OH.

H. W.

Pigment of *B. violaceus*. II. Pyrrolic nucleus of violacein. W. C. TOBIE (Proc. Soc. Exp. Biol. Med., 1936, 34, 620—622).—Violacein contains C 69.28, H 6.79, O 16.45, N 4.83, and ash 2.65%. The ash contains Fe. The mol. contains one or more pyrrole nuclei, probably with hydrocarbon side-chains. It is sol. in  $Et_2O$  and light petroleum, but insol. in EtOH, and is similar to the pigment of *B. prodigiosus*.

P. G. M.

Chemical composition of *B. tumefaciens*. E. CHARGAFF and M. LEVINE (Proc. Soc. Exp. Biol. Med., 1936, 34, 675—677).—The  $COMe_2$ -sol. fat has I val. 95.0, sap. val. 201.2, acid val. 53.2, ester val. 148.0; it contains 9% of non-saponifiable matter, 10% of which consists of a sterol mixture. The phosphatide has N 2.2, P 3.4%; it stimulates growth. The defatted bacteria contain 3.5% of a polysaccharide.

P. G. M.

Polysaccharides of *Amylobacter* strains. H. MEISEL (Compt. rend. Soc. Biol., 1936, 123, 173—176).—The polysaccharide obtained by acid extraction in some cases gives protein reactions depending on the medium in which the organism is grown.

H. G. R.

Sonic extraction of labile bacterial constituents. L. A. CHAMBERS and E. W. FLOSDORF (Proc. Soc. Exp. Biol. Med., 1936, 34, 631—636).—Suspensions of *Eberthella typhi* and *S. haemolyticus*, after subjection at  $<15^\circ$  to intense magnetic vibrations of 8900 cycles per sec., yield supernatant fluids on centrifuging which will combine with the antibody

responsible for phagocytosis. These antigens lose their activity in 3 days at 2–4°, but may be stored after rapid drying from the frozen state. P. G. M.

**Properties of different streptococcal fibrinolysins.** E. WITEBSKY and E. NETER (Proc. Soc. Exp. Biol. Med., 1936, **34**, 858–863).—Human hæmolytic streptococci tested for lysin formation in 0.05 and 2.0% glucose broth may fall into one of four groups: (1) production in 2% only, (2) in 0.05% only, (3) in both, (4) in neither. *S. viridans* behaves similarly to *S. hæmolyticus*, which produces lysin in 2% broth. P. G. M.

**Preparation of a soluble dysentery toxin by grinding and extraction of the bacteria.** A. HANSEN (Biochem. Z., 1936, **287**, 35–39).—A method is described for the prep. from the finely ground dysentery bacilli (Shiga) by adsorption on  $\text{Al}(\text{OH})_3$ , elution, and pptn. of a readily sol. toxin in purified condition. The  $\text{CH}_2\text{O}$  toxoid prep. therefrom possesses strong immunising power. P. W. C.

**Phytochemical reduction with *Thermobacterium mobile* (*Pseudomonas Lindneri*).** W. M. CAHILL (Fermentforsch., 1936, **15**, 134–137).—Phytochemical reduction of  $\text{Bu}^n\text{CHO}$  by *P. Lindneri* gives  $\text{C}_5\text{H}_{11}\cdot\text{OH}$ , and that of  $\text{COAc}$ , by yeast gives  $\text{OH}\cdot\text{CMe}(\text{CHMe}\cdot\text{OH})_2$ . E. A. H. R.

**Precipitating action of basic dyes on bacteriophage and bacterial proteolytic enzymes.** A. W. WALKER (Proc. Soc. Exp. Biol. Med., 1936, **34**, 726–728).—*B. coli* bacteriophage and the proteolytic enzymes of *B. pyocyaneus* are completely pptd. by azine and thiazine dyes, but not by oxazines, xanthanes, or  $\text{CHPh}_3$  dyes. P. G. M.

**Variation in animal viruses.** G. M. FINDLAY (J. Roy. Microscop. Soc., 1936, [iii], **56**, 213–299).—A comprehensive review.

**Tobacco-mosaic virus. VII. Preparation of crystalline tobacco-mosaic virus protein.** W. M. STANLEY (J. Biol. Chem., 1936, **115**, 673–678; cf. this vol., 1156).—A method for the prep. of the cryst. protein by fractional pptn. with  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{CaO}$ , etc. is described. The yield from crude globulin preps. is approx. 80%. F. O. H.

**Sedimentation and electrophoresis of the tobacco-mosaic virus protein.** I. B. ERIKSSON-QUENSEL and T. SVEDBERG (J. Amer. Chem. Soc., 1936, **58**, 1863–1867).—Mol. wt. determinations by sedimentation methods indicate that the protein (I) (Stanley, A., 1935, 1181) is not homogeneous; at  $p_H$  6.8 about 65% has  $M$  15–20  $\times 10^6$  provided the dissymmetry const. is the same as for other proteins of high mol. wt. (I) is more polydisperse at  $p_H >$  or  $<$  6.8. Electrophoresis measurements indicate that (I) is practically homogeneous; the isoelectric point is  $p_H$  3.49. H. B.

**Nature of factor-V.** A. Lvov and M. Lvov (Compt. rend., 1936, **203**, 520–522).—Factor-V (I), a principle promoting bacterial growth, is pptd. by  $\text{EtOH}$  and  $\text{Pb}(\text{OAc})_2$  at  $p_H$  9.5 but not by  $\text{Pb}(\text{OAc})_2$  at  $p_H$  6.8 or  $\text{Hg}(\text{NO}_3)_2$  at  $p_H$  7.0, and resists desiccation in a vac. These and biological properties indicate similarity to or identity with the codehydrogenases

(Warburg-Christian co-enzyme and Harden-Young cozymase). F. O. H.

**Activation of silver by acids.** F. LIEB (Arch. Hyg. Bakt., 1936, **116**, 317–320).—The oligodynamic activation of Ag can be promoted only by acids which form insol. or slightly sol. Ag salts, e.g.,  $\text{HCl}$ ,  $\text{H}_2\text{CrO}_4$ . W. L. D.

**Bactericidal power of metals (zinc).** A. BERNI and G. RISTIVO (Boll. sez. Ital., 1936, **8**, 123–125).—Strips of various metals were immersed in nutrient agar and various organisms grown in the agar. Halos free from growth appeared around strips of Fe, Cu, Zn, and Mg but not around Au, Ag, Pb, Sn, Al, or Ni. Zn as sheet, powder, or in solution after contact with distilled  $\text{H}_2\text{O}$  for 24 hr. was toxic to *B. coli*. The decreasing order of toxicity to bacteria of metals is: Zn, Cu, Ag, Mg. Other metals are inactive. W. L. D.

**Bactericidal power of the stomach: some influential factors.** A. HANSZEN (Amer. J. Digest. Dis. Nutrition, 1934, **1**, 723–727).—The bactericidal power of the stomach is increased by feeding 1 hr. prior to ingestion of infected fluids. Foods of high buffer power retain and subsequently release acid. To ensure effective bactericidal action the  $p_H$  of the stomach contents should reach  $>2$ . CH. ABS. (p)

**Properties acquired by plant extracts after inoculation with bacteria or toxins pathogenic to animals.** T. FRÉMONT (Compt. rend. Soc. Biol., 1936, **123**, 418–420).—The development of antibodies increases or decreases the virulence of the bacteria when injected, depending on whether they are lytic or coagulating. H. G. R.

**Bactericidal action of sea-water.** C. E. ZOBELL (Proc. Soc. Exp. Biol. Med., 1936, **34**, 113–116).—Although fresh- $\text{H}_2\text{O}$  bacteria may be acclimatised to grow in sea- $\text{H}_2\text{O}$  unacclimatised strains as well as sewage and other bacteria are killed by natural, autoclaved, and Berkefeld-filtered sea- $\text{H}_2\text{O}$ . Sea- $\text{H}_2\text{O}$  probably contains a bactericidal agent, other than salts. Its potency is diminished by autoclaving and by addition of org. matter. Survival of sewage bacteria is favoured by water containing 5 and 10% of sea- $\text{H}_2\text{O}$ . W. McC.

**4-n-Alkylpyrogallols.**—See this vol., 1503.

**Cardiac tonus under the influence of adrenaline and acetylcholine.** W. TOMASZEWSKI (Pflüger's Arch., 1936, **237**, 260–272). M. A. B.

**Similarity of action of the adrenal medulla hormone and synthetic adrenaline.** G. KAHNSEN and O. MERTENS (Pflüger's Arch., 1936, **237**, 699–709).—Injection of synthetic adrenaline produced exactly the same effects on blood distribution, mobilisation of the blood reserves, minute-vol., etc. in the dog as did the hormone liberated by stimulation of the secretory nerves of the left adrenal. M. A. B.

**Effect of adrenaline on the activity of the heart.** K. GOLLWITZER-MEIER, K. KRAMER, and E. KRÜGER (Pflüger's Arch., 1935, **237**, 639–650). M. A. B.

**Effect of adrenaline on the blood-vessels in resting and working muscles.** O. MERTENS, H.

REIN, and F. G. VALDECASAS (Pflüger's Arch., 1935, 237, 454—475).  
M. A. B.

Weight changes following the use of glycerol extract of adrenal cortex. R. G. HOSKINS and H. FREEMAN (Endocrinol., 1936, 20, 565—566).  
R. N. C.

Influence of adrenaline and cortin on oxidised and reduced glutathione in the blood. E. ZUNZ and O. VESSELOVSKY (Compt. rend. Soc. Biol., 1936, 123, 114—116).—Intravenous injection of adrenaline or cortin increases the reduced and total glutathione in the red cells.  
H. G. R.

Adrenaline hyperglycæmia and variations in bile-sugar. G. BALTACEANO, C. VASILIU, and T. BUDEANU (Compt. rend. Soc. Biol., 1936, 123, 56—58).—Parallel with the increase in blood-sugar there is an increase in both free and protein-sugar in the bile.  
H. G. R.

Fat absorption after adrenalectomy. F. VERZAR and L. JEKER (Pflüger's Arch., 1936, 237, 14—18). Adrenalectomised rats showed no synthesis of neutral fat in the cells of the intestine although penetration of free fatty acids was not inhibited. Injection of adrenal cortical hormone restored normal fat synthesis.  
M. A. B.

Potassium in adrenal deficiency. C. I. URECHIA, G. BENETATO, and RETEZEANU (Compt. rend. Soc. Biol., 1936, 123, 197—200).—After adrenalectomy, K is diminished in the kidney, spleen, muscles, heart, and liver and increased in the brain of the frog.  
H. G. R.

Glucose absorption and glycogen production in the hypophysectomised rat. L. L. BENNETT (Proc. Soc. Exp. Biol. Med., 1936, 34, 277—279).—In hypophysectomised rats the rate of absorption of glucose (I) is about 35% < that in normal rats, the glycogen (II) contents of the liver and muscle are abnormally low, and the increase in the (II) contents following consumption of (I) is < that in normal rats.  
W. McC.

Carbohydrate levels in fasted and fed hypophysectomised rats. J. A. RUSSELL (Proc. Soc. Exp. Biol. Med., 1936, 34, 279—281).—Liver- and muscle-glycogen and blood-sugar vals. are normal in fully fed but low in fasted hypophysectomised rats. The low vals. are raised to normal but not maintained by giving carbohydrates.  
W. McC.

Pituitary-thyroid-gonad relationship. S. L. LEONARD (Proc. Soc. Exp. Biol. Med., 1936, 34, 599—600).—Follicle-stimulating hormone from either pituitary or urinary sources is more effective in the absence of the thyroid; the luteinising hormone is unaffected.  
P. G. M.

Relationship of the anterior pituitary gland to thyroid and ovary. L. LOEB, J. SAXTON, and S. J. HAYWARD (Endocrinol., 1936, 20, 511—519).—The anterior pituitary gland of cattle, sheep, and pigs contains a substance, "atresin" (I), that destroys follicles in guinea-pig ovaries. It appears possible to obtain extracts from cattle glands that contain (I) in effective concn. with little or no thyroid-stimulating (II) or luteinising hormone (III). (I), (II), and (III) are usually in association with one another,

but can be separated. (II) is associated with the follicular growth-maturation hormone in some human glands, and is not essential for activation of (III). A method of demonstrating the active substances *in situ* is described.  
R. N. C.

Ovaries after administration of a gonadotropic principle of anterior pituitary. E. C. HANBLEEN (Endocrinol., 1936, 20, 321—328).  
R. N. C.

Fat storage in the liver by treatment with the fat-metabolism hormone of the anterior lobe of the pituitary. K. J. ANSELMINO, F. HOFFMANN, and E. RHODEN (Pflüger's Arch., 1936, 237, 515—516).  
M. A. B.

Action of hormones and of maintenance in the dark on the content of pressor and oxytocic factors in the posterior pituitary gland. A. SIMON (Arch. exp. Path. Pharm., 1936, 182, 584—588).—Administration of pituitary, thyroid, and pituitary thyrotropic extracts and of insulin to guinea-pigs, or keeping the animals in the dark, is without effect.  
F. O. H.

Effect of posterior pituitary extracts on sodium balance in health and in diabetes insipidus. F. M. SMITH and E. M. MACKAY (Proc. Soc. Exp. Biol. Med., 1936, 34, 116—118).—Excretion of Na and Cl was increased and the Na and Cl balance rendered negative without change in urinary vols. by administration of the extract to a healthy subject. In diabetes insipidus the same dose caused no increase in NaCl excretion.  
W. McC.

Sex hormones. J. FREUD (Chem. Weekblad, 1936, 33, 632—637).—A summary of the chemistry and action of the various sex hormones.  
S. C.

Analyses of urine of the chimpanzee for oestrogenic content during various stages of the menstrual cycle. E. ALLEN, A. W. DIDDLE, T. H. BURFORD, and J. H. ELDER (Endocrinol., 1936, 20, 546—549).—The content is max. at the time of max. genital swelling.  
R. N. C.

Extraction of both the gonadotropic and (free or total) oestrogenic hormones from a single urine sample. S. C. FREED and O. HECHTER (Endocrinol., 1936, 20, 396—397; cf. this vol., 902).—The gonadotropic hormone is pptd. from the urine with  $H_2WO_4$  and, after removal of adsorbed oestrin (I), is separated from impurities by fractional pptn. with alkaline aq.  $COMe_2$ . Free (I) is extracted from the urine filtrate by the  $H_2WO_4$  method, whilst combined (I) is liberated by boiling the urine with HCl and neutralising before extraction.  
R. N. C.

Isolation from ovarian tissue of a crystalline substance possessing high oestrogenic properties. R. H. ANDREW and F. FENGER (Endocrinol., 1936, 20, 563—564).—After rapid saponification of the fatty portion of whole ovaries with KOH-EtOH at low temp., the unsaponifiable material is extracted from the dil. solution, and the extract evaporated. Cholesterol is removed by boiling with EtOH and chilling, and other impurities by repeated pptn. with dil. aq. NaOH. Subsequent extraction with  $Et_2O$  and crystallisation from EtOH affords a substance,  $C_{26}H_{41}O_2N$  (?), m.p.  $95.1^\circ$  (uncorr.), mol. wt. 320, active in doses of  $10^{-5}$  mg. in rats.  
R. N. C.

Presence of oestrogenic hormones in the ova and ovaries of fish. A. I. WEISMAN, C. W. COATES, and R. L. MOSES (Endocrinol., 1936, 20, 561—562).—The hormones, if present at all in whitefish ova and herring ovaries, are not in sufficient concn. to produce oestrus in mice. R. N. C.

Oestrin-deprivation theory of menstruation. C. F. FLUHMANN (Endocrinol., 1936, 20, 318—320). R. N. C.

Effect of injection of residual ovarian extracts. H. W. MARLOW (Endocrinol., 1936, 20, 339—341). R. N. C.

Structural changes induced in the anterior pituitary by injections of oestrin. J. M. WOLFE and C. S. CHADWICK (Endocrinol., 1936, 20, 503—510). R. N. C.

Modification of the Frank-Goldberger blood-oestrin test. T. NEUSTAEDTER (Endocrinol., 1936, 20, 639—642). R. N. C.

Tube-locking of ova by oestrogenic substances. R. WHITNEY and H. O. BURDICK (Endocrinol., 1936, 20, 643—647). R. N. C.

Oestrogenic substances of hypertrophied prostatic tissue and urine. J. B. HAMILTON, C. L. DEMING, and E. ALLAN (Proc. Soc. Exp. Biol. Med., 1936, 34, 193—194).—Hypertrophied prostatic tissues and urine from patients of 60—80 years contained no oestrogenic substances before or after prostatectomy. W. McC.

Effect of combined administration of oestrone and progesterone in adult ovariectomised rats. H. SELYE, J. S. L. BROWNE, and J. B. COLLIP (Proc. Soc. Exp. Biol. Med., 1936, 34, 198—200).—In ovariectomised rats the effect of administration of daily doses of 0.03 mg. of oestrone (I) is modified by simultaneous administration of 0.4 mg. of progesterone (II). (I) and (II) together cause mucification of the vaginal epithelium and second-stage progestational proliferation of the uterus, the vaginal effect being modified even in cases in which the uterine effect is unchanged. W. McC.

Epithelial regeneration by the action of the oestrogenic hormone and in avitaminosis-A. W. SCHMIDT (Beitr. Path. Anat. allg. Path., 1935, 96, 129—146; Chem. Zentr., 1936, i, 370).—No relation was apparent between epithelial growth and the level of vitamin-A in rats. A. G. P.

Concentration of gonadotropic substance from pregnancy urine. H. L. FEVOLD and F. L. HISAW (Proc. Soc. Exp. Biol. Med., 1936, 34, 712—714).—Pregnancy urine is extracted with cresol and the hormone is pptd. by addition of 2 vols. of  $\text{COMe}_2$ . The method is more efficient than tannic acid or  $\text{BzOH}$  adsorption. P. G. M.

Water-soluble pregnandiol complex from human pregnancy urine. E. M. VENNING and J. S. L. BROWNE (Proc. Soc. Exp. Biol. Med., 1936, 34, 792—793).—Pregnandiol-glycuronic acid as thin plates, m.p. 268—271° (decomp.), has been isolated from human pregnancy urine (9th month) by extraction with  $\text{BuOH}$ , dissolution of the residue in 0.5*N*- $\text{NaOH}$ , re-extraction with  $\text{BuOH}$ , and crystall-

isation of the residue from  $\text{H}_2\text{O}$  and  $\text{EtOH}$ . The yield is 40—50 mg. per litre. P. G. M.

Relative effectiveness of progestin in hypophysectomised and normal rabbits. S. R. M. REYNOLDS, W. M. FIROR, and W. M. ALLEN (Endocrinol., 1936, 20, 681—682). R. N. C.

Effect of testosterone on the growth of the comb in *Triton cristatus*. W. FLEISCHMANN and S. KANN (Pflüger's Arch., 1936, 237, 517—518). M. A. B.

Effect of testosterone on the mammary gland. H. SELYE, C. S. McEVEN, and J. B. COLLIP (Proc. Soc. Exp. Biol. Med., 1936, 34, 201—203).—Slight development of the mammary tissue and marked secretion of milk are induced in immature male and female rats in presence and absence of the gonad by administration of 0.2 mg. of testosterone benzoate. W. McC.

Presence of an excess of "male" (comb-growth and prostate-stimulating) hormone in virilism and pseudo-hermaphroditism. S. L. SIMPSON, P. DE FREMERY, and A. MACBETH (Endocrinol., 1936, 20, 372). R. N. C.

*cis*- and *trans*-Androstanone-3-carboxylic acid, an oestrus-producing male hormone derivative, and *epicholesterol*.—See this vol., 1506.

Artificial production of oestrogenic substances from sterols.—See this vol., 1505.

Crystalline insulin. VIII. Standardisation by the "area of activity" method. H. KOHL (Arch. exp. Path. Pharm., 1936, 182, 550—559).—Assays in rabbits by determination of the "area of activity" (A., 1934, 223) are applicable only with intravenous injection. The method indicates crystalline insulin to have an activity of approx. 16 international units per mg. F. O. H.

Measurement of insulin action. P. O. GREELEY, H. C. BERGMAN, D. B. TYLER, and D. R. DOURY (Proc. Soc. Exp. Biol. Med., 1936, 34, 121—123).—In order to maintain nearly sugar-free urine and a normal blood-sugar level in depancreatized dogs, 0.0094—0.014 unit of insulin per kg. of body-wt. must be administered. W. McC.

Action of phenylcarbimide on insulin. II. Chemistry of insulin and its phosphate-lowering power. W. E. GAUNT and A. WORMALL (Biochem. J., 1936, 30, 1915—1926; cf. A., 1935, 441).—The inactivation by  $\text{PhNCO}$  (I) and  $p\text{-C}_6\text{H}_4\text{Br}\cdot\text{NCO}$  (II) of the hypoglycaemic activity of insulin (III) in rabbits is accompanied by a parallel inactivation of the hypophosphatemic power. Inactivation in both cases appears to be due to interaction with the free  $\text{NH}_2$  groups of (III). (I) does not react, under conditions similar to those maintained in the prep. of phenylcarbamidoprotein derivatives, with the OH of tyrosine, the  $\text{CO}\cdot\text{NH}_2$  of asparagine (IV) and glutamine (V), or the glyoxaline group of histidine (VI) nor is there any significant change in the S·S linking. The SH of cysteine (VII) reacts but (VII) is not present in (III). (I) also reacts with the pyrrolidine group of proline (VIII) and to some extent with the guanidino-group of arginine (IX). The following compounds

were prepared : (I) *derivatives* of (VII), m.p. 139—140° (decomp.), in which both SH and NH<sub>2</sub> are blocked; of  $\alpha$ -thiolpropionic acid, m.p. 140—141° (decomp.); of thiolacetic acid, m.p. 144—146° (decomp.); of (IV), m.p. 163° (decomp.) (*hydantoin*, m.p. 231—233°); of (V), m.p. 161° (decomp.) (*hydantoin*, m.p. 160—161°); (II) *derivatives* of (VIII), m.p. 169° (decomp.); of (VI), m.p. 177—178° (decomp.); of (IV), m.p. 175—176° (decomp.) (*hydantoin*, m.p. 220°); of (V), m.p. 189° (*hydantoin*, m.p. 200—201°). With (IX) mixtures of mono- and di-derivatives were obtained with both (I) and (II). P. W. C.

**Effect of various substances on the action of insulin.** A. M. FISHER and D. A. SCOTT (J. Pharm. Exp. Ther., 1936, 58, 93—104).—The effect of insulin (I) is prolonged by admixture with spermine + Zn or an ox thymus prep. + Zn, the presence of Zn being essential in both cases. Suspensions of (I) containing no potency in solution do not differ in activity from a solution of the same (I). H. G. R.

**Insulin with protamine.** D. A. SCOTT and A. M. FISHER (J. Pharm. Exp. Ther., 1936, 58, 78—92).—The action of insulin (I) is prolonged when administered in conjunction with protamine (prep. from fish testes described), this being further enhanced if traces of Zn are first added to (I), especially when a low-ash prep. is used. A method of assay on rabbits is described. H. G. R.

**Treatment of diabetes mellitus with insoluble insulin compounds.** P. A. GRAY (Endocrinol., 1936, 20, 461—472).—Insulin (I) tannate shows a hypoglycaemic action > that of commercial (I) but approx. equal to that of protamine insulinate. It can control diabetes when administered alone or with (I). Its relative insolubility delays absorption and hence decreases the rate of liberation of free (I). R. N. C.

**Cutaneous absorption of insulin.** R. H. MAJOR (Proc. Soc. Exp. Biol. Med., 1936, 34, 775—778).—Insulin in OH·[CH<sub>2</sub>]<sub>2</sub>·OEt is absorbed through the skin of the rabbit, producing a definite fall in blood-sugar. P. G. M.

**Response of normal and hypophysectomised Rhesus monkeys to insulin.** P. E. SMITH, H. H. TYNDALE, L. DOTTI, and E. T. ENGLE (Proc. Soc. Exp. Biol. Med., 1936, 34, 250—251).—Injection of insulin in doses of 0.0625 unit per kg. reduced the blood-sugar in normal monkeys by 14% and in hypophysectomised monkeys by 35% in 30 min. W. McC.

**Fate of the sugar disappearing under the influence of insulin.** V. VENDEG (Pflüger's Arch., 1936, 237, 683—698).—Insulin causes conversion of sugar into glycogen (I) and then into fat in the liver. The final result may be an increase or decrease of (I) accompanied by a decrease or increase of fat, respectively. More sugar disappears in the former case. Occasionally where the initial fat content of the liver is high, insulin may decrease both (I) and fat. Decrease in fat is due to translocation to the fat depots. M. A. B.

**Diuresis during insulin hypoglycaemia.** V. LE CLERC (Compt. rend. Soc. Biol., 1936, 123, 273—275).—The diuresis, which diminishes and may become

total when the blood-sugar is very low, does not appear to be due to a blockage of H<sub>2</sub>O absorption in the region of the stomach. H. G. R.

**Sensitivity of blood-sugar to insulin after pancreatectomy in dogs.** E. S. PANAYOTOPOULOS (Compt. rend. Soc. Biol., 1936, 123, 403—404).—An abnormal sensitivity was noted during the 48 hr. following the operation. H. G. R.

**Diminution of the hyperpolypeptidaemia, secondary to cellular destruction, by insulin with or without glucose.** O. LAMBRET, J. DRIESSENS, and H. MALATRAY (Compt. rend. Soc. Biol., 1936, 123, 12—13). H. G. R.

**Biologically active calcium of the aqueous humour in hyperparathyroidism and acute and latent tetany.** F. MATHIEU (Compt. rend. Soc. Biol., 1936, 123, 112—114).—Variations in plasma-Ca during hypo- and hyper-parathyroidism are accompanied by corresponding variations in the humour. H. G. R.

**Metabolic effects of human thyroglobulin and its proteolytic cleavage products.** W. T. SALTER and J. LERMAN (J. Clin. Invest., 1935, 14, 691—695).—Clinical assay of the metabolic potency of thyroglobulin (I) in terms of I showed that (I) from "colloid adenomatous" glands and iodised toxic glands, thyroxine (II), peptone from either type of gland, and synthetic racemic glycythyroxine were equiv. All preps. approximated to natural (II) polypeptide when assayed in human myxoedema. Di-iodopeptone produced no effect. CH. Abs. (p)

**Iodine tolerance test for the investigation of thyroid function.** E. M. WATSON (Endocrinol., 1936, 20, 358—362).—The rate of disappearance of I from the blood-stream of patients injected intravenously with Lugol's solution is increased in thyrotoxicosis and reduced in hyperthyroidism. R. N. C.

**Assay of blood and urine for thyrotropic hormone in thyrotoxicosis and myxoedema.** S. HERTZ and E. G. OASTLER (Endocrinol., 1936, 20, 520—525). R. N. C.

**Similarity of the iodine remission in experimental anterior hypophyseal hyperthyroidism, the hyperthyroidism of acromegaly, and that of exophthalmic goitre.** H. B. FRIEDGOOD (Endocrinol., 1936, 20, 526—536).—The depressions of metabolic rate produced by NaI in all three conditions are of the same order. R. N. C.

**Effect of pregnancy on resistance to thyroxine; creatine content of the maternal and foetal myocardium.** M. BODANSKY and V. B. DUFF (Endocrinol., 1936, 20, 537—540).—Tolerance to thyroxine is increased in pregnancy in the rat. Creatine falls in the maternal but not the foetal myocardium in hyperthyroidism. R. N. C.

**Age as a factor in the resistance of rats to thyroxine.** Creatine content of the tissues in experimental hyperthyroidism. M. BODANSKY and V. B. DUFF (Endocrinol., 1936, 20, 541—545).—Resistance to thyroxine is high in immature rats. Myocardial creatine (I) is reduced in young and old

hyperthyroid rats, but young rats withstand greater depletion than do old rats. (I) falls in skeletal muscle and rises in the testes of hyperthyroid rats. Cessation of thyroxine treatment brings ventricular (I) to normal levels in 7—14 days. R. N. C.

**Relation between insensible water loss and heat production in hyperthyroidism.** D. R. GILLIGAN and G. EDSALL (*J. Clin. Invest.*, 1935, **14**, 659—664).—In hyperthyroidism the insensible  $H_2O$  loss and the % of total heat lost by evaporation decreased. The decline in  $H_2O$  loss through the lungs but not that through the skin  $\propto$  the decreased metabolism. CH. ABS. (p)

**Role of vitamins in fat and lipin metabolism.** T. KALAJA (*Suomen Kem.*, 1936, **9**, B, 21—22; cf. this vol., 389).—The I val. and the total fatty acid (I), phosphatide, free cholesterol (II), and cholesteryl ester contents of the heart-muscle of vitamin-A-deficient rats were equal to those of control animals, but in the brain (II) was reduced. Deficiency of the vitamin-B complex or of -B factors except -B<sub>1</sub> lowered the I val. and (I) content in the skin and blood. Deficiency of -C and inanition caused no change in the above vals. in guinea-pigs. A. L.

**Utilisation by the rat of vitamin-A and carotene administered in different media.** K. H. COWARD (*Biochem. J.*, 1936, **30**, 1878—1882).—Responses of large nos. of rats to the vitamin-A of cod-liver oil (true -A), of plant tissues [probably wholly carotene (I)], of butters (largely true -A), and of margarines containing vitamin concentrates (-A in different solvents, mostly vegetable oils) showed no significant differences. Differences in results obtained by dissolution of (I) in various oils cannot be due to differences in utilisation of -A or (I) contained in them. P. W. C.

**Relative vitamin-A potency of carotene fed in butter fat and cottonseed oil.** H. R. KRAYBILL and C. H. SHREWSBURY (*J. Nutrition*, 1936, **11**, 103—110).—Treatment of melted butter fat with Lloyd's reagent removes natural yellow pigments and vitamin-A without removal or destruction of the natural antioxidants. Quinol (up to 100 mg. per 100 g. of oil) does not seriously interfere with the utilisation of carotene (I) from cottonseed oil (II). (I) in butter fat decolorised with Lloyd's reagent is less readily utilised than when dissolved in (II). A. G. P.

**Vitamin-A reserve of embryo and baby chicks.** A. D. HOLMES, F. TRIPP, and P. A. CAMPBELL (*J. Nutrition*, 1936, **11**, 119—128).—The -A contents of egg yolks during hatching and of livers of young chicks are recorded. The rapid increase of -A in livers after hatching is derived from yolk reserves. A. G. P.

**Microscopical observation of the fluorescence produced during reversible production of vitamin-A in the retina during visual perception.** N. VON JANCÓ and H. VON JANCÓ (*Biochem. Z.*, 1936, **287**, 289—290).—Microscopical examination in filtered ultra-violet light of the retina of rats shows that after max. light adaptation there is strong fluorescence due to vitamin-A, whilst after max. dark adaptation there is no fluorescence, -A having dis-

appeared. The light destroys -A in 1—4 min. with disappearance of the fluorescence. Power to exhibit strong fluorescence is conferred on rat's liver by giving 7 mg. of carotene daily and by feeding Vogan for 3—4 weeks. At max. dark adaptation -A of the retina is converted into visual purple and stored in the rods, whilst on adaptation to light the carotenoid produced by photochemical decomp. of the purple reappears as -A, which is stored in the pigment cells. W. McC.

**Accuracy of vitamin-A determinations. Starting point of the test period.** K. H. COWARD (*Biochem. J.*, 1936, **30**, 2009—2011).—The greatest accuracy is obtained in determinations of vitamin-A by the "increase in wt." method when the test period is counted from the first day of dosing. P. W. C.

**Influence of the vitamin-B complex on keto-acid metabolism.** P. E. SIMOLA (*Suomen Kem.*, 1936, **9**, B, 20—21; cf. this vol., 646).— $\alpha$ -Ketoglutaric acid is excreted in the urine of rats during avitaminosis-B and when only vitamin-B<sub>1</sub> is included in the diet. No  $AcCO_2H$  or  $AcCHO$  was detectable. A. L.

**Influence of the length of the test period on the accuracy obtainable in a vitamin-B<sub>1</sub> test.** K. H. COWARD (*Biochem. J.*, 1936, **30**, 2012—2015).—The average variance in response of rats to doses of vitamin-B<sub>1</sub> is determined in tests lasting 1, 2, and 3 weeks, and the slopes of curves of response relating increase in wt. and the dose are measured. The probable errors of determinations of -B<sub>1</sub> potency of a substance by comparison with the International standard tested simultaneously, when 10 animals are used on each substance and when the tests are carried on for 1, 2, and 3 weeks, are about 18, 12.5, and 10%, respectively. Thus the accuracy is much > with -A determinations and is only very slightly increased by extending the tests from 2 to 3 weeks. The curve of response of bucks is only a very little steeper than for does and it is not necessary to have equal nos. of each in each group. P. W. C.

**Assay of League of Nations standard preparation of vitamin-B<sub>1</sub>.** B. C. P. JANSEN (*Z. Vitaminforsch.*, 1936, **5**, 254—256).—1 g. of the standard prep. contains approx. 0.3 mg. of -B<sub>1</sub> hydrochloride. J. N. A.

**Crystallisation of vitamin-B<sub>1</sub>.** L. ROSENTHALER (*Z. Vitaminforsch.*, 1936, **5**, 276—277).—Vitamin-B<sub>1</sub> can be pptd. in cryst. condition by K tetranitro-diamminocobaltiate and by Reinecke salt. Most alkaloid precipitants give only amorphous ppts. J. N. A.

**Constitution of oryzanin (vitamin-B<sub>1</sub>).**—See this vol., 1526.

**Aneurin. III. Methyl  $\alpha$ -chloro- $\gamma$ -hydroxy-propyl ketone and its application to thiazole synthesis.**—See this vol., 1526.

**Constitution of aneurin (vitamin-B<sub>1</sub>).** R. GREWE (*Naturwiss.*, 1936, **24**, 657—662)—A lecture.

**Vitamin-B<sub>1</sub> (oryzanin, torulin, aneurin).** R. A. PETERS (*Current. Sci.*, 1936, **5**, 207—214).—A discussion of the chemistry and mode of action.

**Vitamin-B<sub>2</sub> and its relation to canine black tongue.** C. J. KOEHN, jun., and C. A. ELVEHJEM (*J. Nutrition*, 1936, 11, 67—76).—Black tongue was cured by liver extracts rich in -B<sub>2</sub> but freed from peptoflavin (I). (I) obtained from the extracts was without effect.

A. G. P.

**Relation between vitamin-B<sub>2</sub> and the hormone of the adrenal cortex.** F. VERZAR and L. LASZT (*Pflüger's Arch.*, 1936, 237, 476—482).—In rats the adrenal cortical hormone (I) was effective only when the diet contained flavin (II) (provitamin-B<sub>2</sub>). Adrenalectomised animals could be kept alive with flavin phosphate (III) in place of (I) but (II) itself was inactive. From the similarity of action between (I) and (II) it is concluded that (I) promotes the production of (III) from (II), so that (III) is vitamin-B<sub>2</sub>.

M. A. B.

**Synthesis of flavins.**—See this vol., 1525.

**Influence of ascorbic acid on the glycogen content of the liver of hyperthyroidised guinea-pigs.** L. HIRSON (*Biochem. Z.*, 1936, 287, 126—129).—Intraperitoneal injection of 25 mg. of ascorbic acid (I) per day causes in 12 days a 60% increase of liver-glycogen (II). The decrease of (II) brought about by intraperitoneal injection of thyroxine (0.1 mg. per day) is inhibited by (I) or by "cebron." "Cortidyn" injected with (I) did not increase the action of (I).

P. W. C.

**Stabilisation of vitamin-C by adrenaline.** M. YAMAMOTO (*Z. physiol. Chem.*, 1936, 243, 266—269; cf. Abderhalden, A., 1934, 1138).—The oxidation of ascorbic acid (I) (0.602 mg. in 3 c.c.) at  $p_H$  7.38 in the dark is prevented to the extent of 93% by addition of 0.7 mg. of *l*-adrenaline (II) but when *dl*-(II) is used the max. extent is only 43%. No oxidation of (II) occurs while (I) is present. Since *dl*-(II) exerts its max. effect when the ratio (I) : *dl*-(II) is 1 : 1 and since the bis-2 : 4-dinitrophenylhydrazones of (I) is much more slowly produced when (II) [especially *l*-(II)] is present than when it is absent it is possible that (II) combines with (I).

W. McC.

**Divergent physiological effects of synthetic and "natural" ascorbic acids.** L. HAVAS and I. GÁL (*Nature*, 1936, 138, 586—587; cf. A., 1935, 1430).—Vitamin-C from paprika still stimulates growth in wheat seedlings at a concn. of 0.1%. The inhibitory effect at 0.5% concn. is < that produced by the same concn. of synthetic ascorbic acid (I). With synthetic (I) inhibition appears at a concn. of 0.1%, and may be due to an impurity.

L. S. T.

**Ascorbic acid content of the organs of rats in vitamin-B deficiency.** J. MELKA (*Pflüger's Arch.*, 1936, 238, 74—77).—On a vitamin-B-free diet ascorbic acid (I) synthesis was decreased. The content of (I) was decreased most in the liver, less in the brain, the ileum wall, and the testicles, and very little in the adrenals.

M. A. B.

**Ascorbic acid content of different parts of the central nervous system and of the peripheral nerves.** J. MELKA (*Pflüger's Arch.*, 1936, 237, 210—221).—The following decreasing order of ascorbic acid content was established in man and various animals: pituitary body, cortex cerebelli, cerebral

cortex, basal ganglia, medulla oblongata, medulla spinalis, white matter of the central nervous system.

M. A. B.

**Excretion of vitamin-C in normal individuals following a comparable quantitative administration in the form of orange juice, ascorbic acid by mouth, and ascorbic acid intravenously.** E. E. HAWLEY, D. J. STEPHENS, and G. ANDERSON (*J. Nutrition*, 1936, 11, 135—145).—Excretion of -C remained at normal levels for several days after changing to a -C-deficient diet. Comparable amounts of -C given as orange juice or as ascorbic acid (I) produced similar changes in urinary excretion. Intravenously administered (I) was excreted more rapidly and more completely than when given by mouth. Variations in the intake of -C had no influence on the (I) content of whole blood.

A. G. P.

**Blood-cell count and ascorbic acid content in guinea-pigs.** H. VON EULER and M. MALMBERG (*Z. physiol. Chem.*, 1936, 243, 121—143).—Anæmia is not regularly produced in guinea-pigs by a vitamin-C-free but otherwise adequate diet, but -C-free milk diet produces anæmia and reduction in the leucocyte content of the blood. This content is also greatly (66%) reduced in scurvy produced by other -C-free diets; the accompanying diminished immunity is possibly due to lack of -C. Diminution of leucocytes does not occur if ascorbic acid is added to the -C-free diet.

W. McC.

**Vitamin-C in vegetables. III. Oxidation of ascorbic acid by metallic catalysts.** G. L. MACK and Z. I. KERTESZ (*Food Res.*, 1936, 1, 377—382).—The catalytic activity of Cu is considerably increased by the addition of small amounts of Fe, which by itself has no such activity. 2% of HPO<sub>3</sub> in the acid used to extract ascorbic acid retards oxidation sufficiently to allow analysis to be carried out. Only a small amount of the Cu in many vegetables appears in the extract in an active form.

E. C. S.

**Determination of ascorbic acid.** P. MANCEAU, A. A. POLICARD, and M. FERRAND (*Bull. Soc. Chim. biol.*, 1936, 18, 1369—1386).—The sulphotungstate method of Fujita *et al.* (A., 1935, 793) for the determination of ascorbic acid (I) is modified by the introduction of a titrimetric determination of the reduced tungstate using K<sub>3</sub>Fe(CN)<sub>6</sub>. The method, however, is not sp. for (I), and other substances, particularly adrenaline, interfere. 2 : 6-Dichlorophenol-indophenol is more sp. and in presence of phenols gives better results.

A. L.

**Determination of ascorbic acid by titration.** H. CHEFTEL and M. L. PIGEAUD (*Nature*, 1936, 138, 799).—Increased accuracy is obtained in the Harris-Ray method by cooling the reactants to 0°, at which temp. oxidation of ascorbic acid is retarded.

L. S. T.

**Determination of ascorbic acid by titration.** I. GÁL (*Nature*, 1936, 138, 799).—Ascorbic acid is extracted with HPO<sub>3</sub> and allowed to react with methylene-blue, excess of which is titrated with 0.5% TiCl<sub>3</sub>.

L. S. T.

**Identity of the indophenol-reducing substances in brain tissue.** F. G. YOUNG (*Biochem. J.*, 1936,

30, 1883—1885).—The properties of the indophenol-reducing substance (I) in crude brain extracts differ in some respects from those of ascorbic acid (II). The reducing properties of (II) are, however, greatly modified by the presence of glutathione and other substances present in the extracts. (I) added to "inactivated" crude brain extract re-establishes the properties of the normal crude extract. (I) is probably (II). P. W. C.

**Strongly reducing substance accompanying ascorbic acid in the adrenals of the ox.** E. OTT, K. KRAMER, and W. FAUST (Z. physiol. Chem., 1936, 243, 199—201).—The MeOH extract of 1 kg. of the adrenals after treatment in  $N_2$  with  $Ba(OAc)_2$ , filtration, addition of  $Pb(OAc)_2$ , and subsequent purification yields 0.15—0.20 g. of an amorphous, hygroscopic,  $H_2O$ -sol., reducing substance (I) (N 5.21, P 0.544—0.554%), which is very sensitive to the action of  $O_2$ , reduces 4.6% of the amount of 2:6-dichlorophenol-indophenol reduced by an equal wt. of ascorbic acid, reduces hot but not cold Fehling's solution, and has only slight or no antiscorbutic action. W. McC.

**Antirachitic activity of sterol derivatives.** W. GRAB (Z. physiol. Chem., 1936, 243, 63—89).—The antirachitic activity of the crude and cryst. (vitamin- $D_3$ ) ultra-violet irradiation product of 7-dehydrocholesterol (I) and that of the crude ultra-violet irradiation products of 22-dihydroergosterol (II), 7-dehydrositosterol (III), and 7-dehydrostigma-sterol (IV) was compared with the activity of cryst. - $D_2$  (V), halibut-liver oil and concentrate, and cryst. material from the liver oil of the tunny by preventive and curative experiments on rats (experimental error  $\pm 30\%$ ) and chickens ( $\pm 50\%$ ). With rats the amounts of (V), crude irradiation product of (I), of (II), and of (III) required to produce the same result as the active dose of tunny-liver oil concentrate taken as unity are 32, 0.6—0.8, 2.5—10.0,  $>13$ , respectively, and with chickens the corresponding vals for (V), crude and cryst. irradiation product of (I), and crude irradiation product of (II) are 32—80, 0.4, 0.6, and 1.6—2.5; crude irradiation product of (IV) has a relatively very low activity. The cryst. product from tunny-liver oil has activity indistinguishable from that of cryst. irradiation product of (I) and hence is identical with cryst. irradiation product of (I) which is therefore provitamin- $D_3$ . Probably the irradiation product of (II) is closely related to that of (I). Sterols of the  $C_{29}$  series cannot serve as provitamin- $D$ . W. McC.

**Antirachitic values of irradiated yeast and of cod-liver oil.** E. L. COMPERE, T. E. PORTER, and L. J. ROBERTS (Amer. J. Dis. Children, 1935, 50, 55—76).—The curative dose of irradiated dried yeast is 1.1—3.3 times that of cod-liver oil (rat units). CH. ABS. (*p*)

**Colorimetric determination of vitamin- $D$ .** H. TZONI (Biochem. Z., 1936, 287, 18—22).—The method described depends on the production of a red-violet colour on heating with  $AlCl_3$  and pyrogallol. The reaction is sp. and is not given by phytosterol, cholesterol, ergosterol, or lumisterol. Suprasterol II gives a feeble colour. P. W. C.

**Chilean fish oils. Vitamin- $D$  content of cod-liver oil.**—See B., 1936, 1054.

**Vitamin- $E$ .** P. SCHOORL (Z. Vitaminforsch., 1936, 5, 246—253).—An improved vitamin- $E$  deficiency diet which contains casein and a high % of potato starch and dextrin, but no lard, is described. Royal jelly (the food of the larva of the honey bee destined to be a queen) shows no - $E$  activity. Daily doses of 0.2 c.c. of wheat-germ oil during pregnancy are sufficient for fertility in rats. The - $E$  concentrate Vibeta shows no anti-sterility activity. J. N. A.

**Vitamin- $E$ . V. Eutropic and anti-sterility activity of wheat-germ oil in comparison with other vegetable oils.** L. SCHIOPPA (Z. Vitaminforsch., 1936, 5, 241—246; see this vol. 392).—Only wheat-germ oil possesses the activities described. J. N. A.

**Vitamin- $E$  in cacao embryo.** H. LABRE and F. H. DE BALSAC (Compt. rend., 1936, 203, 587—589).—Vitamin- $E$ -deficient rats bear litters when cacao germ, but not when a fatty extract presumed rich in - $E$ , is added to the diet. If germ or extract is incorporated in an - $E$ -deficient diet sterility does not occur. J. L. D.

**New essential dietary factor.** C. A. ELVEHJEM, C. J. KOEHN, jun., and J. J. OLESON (J. Biol. Chem., 1936, 115, 707—719).—A dietary factor essential for the growth of rats, not identical with any of the known factors, is present in liver, yeast extracts, and milk. The factor is  $H_2O$ -sol., pptd. from aq. solution by  $EtOH-Et_2O$  or  $COMe_2$ , adsorbed by C, and thermolabile. It is not identical with arginine, cystine, or the  $NH_2$ -acids from blood-fibrin or caseinogen. Rats deficient in this factor shown no sp. symptoms other than lack of growth. F. A. A.

**Influence of temperature on the carbohydrate metabolism, respiration, and morphological development of the tulip.** I. L. ALGERA (Proc. K. Akad. Wetensch. Amsterdam, 1936, 39, 846—855).—The effects of temp. during the later growth stages, during storage of lifted bulbs, and after subsequent planting out are examined. In general, the reducing sugar content declines during late growth, remains at a low level during storage, and increases rapidly some weeks after planting out. Non-reducing sugars begin to increase soon after lifting and continue to do so until nearly the end of the growth period. The starch content rises towards the end of growth, remains high after lifting and during early growth, and declines towards maturity. No optimum temp. for any individual stage is apparent. Optimum conditions for growth are those in which the temp. of successive stages is suitably balanced. A. G. P.

**Electrometric determination of quality of potato tubers.** Redox potential of pulped tuber tissue. H. WARTENBERG and A. HEY (Planta, 1936, 25, 258—281).—The melanin (I) system and its influence in maintaining anaerobic conditions in the tissue are discussed. Addition of electrolytes (notably  $PO_4'''$  buffers of  $p_H >$  that of the pulp) favours (I) formation. The redox potential is an index of the vitality of tubers. A. G. P.

**Relation of hydrogen-ion concentration to the growth and distribution of mosses.** G. J. IKENBERRY (Amer. J. Bot., 1936, 23, 271—279).—The distribution of 46 species of mosses was unrelated to the  $p_H$  of their natural substrates, although closely related species develop best on soils of similar  $p_H$ , and show optimum spore germination in culture solutions of almost identical reaction. The  $p_H$  of soil in which a species becomes dominant bears no relation to that of the culture solution most favourable to germination and development. A. G. P.

**Relation of temperature to the effect of hydrogen- and hydroxyl-ion concentration on *Sclerotinia fruticola* and *Fomes annosus*. Spore germination and growth.** P. E. TILFORD (Ohio Agric. Exp. Sta. Bull., 1936, No. 567, 27 pp.).—The  $p_H$  optimum for spore germination of *S. fruticola* is largely influenced by temp. At every temp. examined germination- $p_H$  curves show two max. with a min. at 6.0. Growth injury by  $H^+$  was that by  $OH^-$ .  $H^+$  was more toxic at higher than at lower temp. The reverse was the case with  $OH^-$ . The optimum  $p_H$  for mycelial extension at a higher temp. was > that at a lower temp. A. G. P.

**Chemistry of cell growth. I, II.** O. RAHN (Cold Spring Harbor Symp., 1934, 2, 57—62, 63—69).—I. Energy exchange in certain plant and bacterial processes is examined. The vitamin requirements of rats for protein synthesis are discussed.

II. Nutritional factors affecting growth rates of bacteria, yeasts, and animals are considered.

CH. ABS. (p)

**Respiration of potato tissue in relation to hydrogen-ion concentration of a surrounding solution.** P. LEMMON (Amer. J. Bot., 1936, 23, 296—302).—The gaseous exchange of potato tissue in various buffer solutions over a  $p_H$  range of 1.5—9.5 is examined. A. G. P.

**Variations in imbibition caused by reciprocal displacement of fixed cations on dead tissues of *Laminaria flexicaulis*.** D. KOHLER (Compt. rend. Soc. Biol., 1936, 123, 394—396).—Ions fixed from immersion in one solution are partly replaced when the solute is changed, with corresponding modification in the imbibition. H. G. R.

**Water and salt content of East African mangroves.** H. WALTER (Ber. deut. bot. Ges., 1936, 54, 76—79).—The difference in osmotic pressure of sap and soil solution is considered in relation to salt intake. A. G. P.

**Effect of nutrients on the water relationships of tomato plants. Influence of light on development, sugar formation, and nutrient absorption of the sugar beet.**—See B., 1936, 1116.

**Significance of the physiological antagonism between calcium and magnesium for plant growth.**—See B., 1936, 1060.

**Uptake of minerals by pineapple plants at different stages of growth.**—See B., 1936, 1115.

**Effect of transpiration on absorption and distribution of mineral salts in plants.** R. O. FREELAND (Amer. J. Bot., 1936, 23, 355—362).—In plants grown under conditions of high transpiration the ash,

Ca, P, K, and dry matter contents were > when transpiration was low, the Ca and K contents being the most affected. In high-transpiration plants, mineral contents increased more in leaves and roots than in stems; Ca and K showed the greatest differences. No correlation was apparent between the mineral content and the dry matter of leaves, stems, and roots. A. G. P.

**Nitrogen losses in green plants.** W. H. PEARSALL and M. C. BILLIMORIA (Nature, 1936, 138, 801—802).—Pure cultures of *Chlorella vulgaris* growing in a medium containing  $NO_3^-$  lose much N, presumably as  $N_2$ . Similar losses occur with daffodil leaves floated on glucose media containing  $NO_3^-$ , but not with org. N. Large losses of N are always associated with low  $NH_4^-$ -N content of the leaf tissues. L. S. T.

**Fat metabolism of germinating pumpkins.** U. WEBER (Ber. deut. bot. Ges., 1936, 54, 70—75).—The I val. of fat in cotyledons of germinating walnuts increases in the early stages and subsequently declines with the rapid development of the seedlings. Similar changes occur in pumpkins except that a double max. occurs in the I val.-time curve. Formation of unsaturated fatty acids is an intermediate step in the utilisation of fats by the seedlings. Addition of KOAc increases the rate of development of seedlings, accelerates the consumption of unsaturated acids, and increases their % utilisation. A. G. P.

**Glutamine metabolism of beet.** H. B. VICKERY, G. W. PUCHER, and H. E. CLARK (Plant Physiol., 1936, 11, 413—420).—Treatment of soil with  $(NH_4)_2SO_4$  increased the glutamine (I) content of root tissue without affecting the asparagine level. (I) acts as a detoxicating agent for  $NH_3$  in the plant, probably through the intermediate formation of glutamic acid and subsequent dehydration of the  $NH_4^+$  salt to form the amide. A. G. P.

**Diurnal variations in the carbohydrate content of leaves.** C. BÉGUIN (Bull. Soc. Chim. biol., 1936, 18, 1387—1395).—In the leaves of *Lonicera alpigena*, L., the amounts of sucrose and glucosides hydrolysed by emulsin increase during the day and decrease during the night. This variation is the reverse of that of the reducing sugars present. In bruised leaves (half leaf method) the glucosides diminish steadily. A. L.

**Thymonucleic acid content of hyperchromatic somatic cell nuclei.** P. F. MILOVIDOV (Planta, 1936, 25, 197—205).—Certain "stimulated" cell nuclei, e.g., mycorrhiza cells of *Neottia nidus avis*, cells of *Heteroda* galls, trichocytes of *Stratiotes aloides* and *Trianea bogotensis*, contain relatively high proportions of thymonucleic acid. A. G. P.

**Production of mucus during decomposition of plant materials. III. Effect of partly aerobic and anaerobic conditions.** J. G. SHRIKHANDE (Biochem. J., 1936, 30, 1789—1794).—The conditions necessary for the production of stickiness in manures (A., 1933, 1334) are further investigated using ragi straw (*Eleusine covacana*) which was decomposed under partly aerobic conditions in presence of different sources of available N, the C:N ratio being adjusted to 30:1 and 10:1. Strong acidities

prevent, whilst high concns. of N and final adjustment of the  $p_H$  to 9 have no effect on, the development of stickiness during fermentation. P. W. C.

**Daily variations in products of photosynthesis, water content, and acidity of leaves towards the end of the vegetative period.** P. P. STANESOU (Amer. J. Bot., 1936, 23, 374—379).—Rhythmic variations in the carbohydrate content of leaves continues until the last days of vegetative growth. Curves for hexoses frequently take an opposite course to those for sucrose (I) and starch (II), especially during the day. (II) accumulation begins later in the morning during the late vegetative period than during the summer. Monosaccharides predominate in petioles, followed in descending order by (II) and (I). No uniform relation exists between carbohydrate and  $H_2O$  contents or the acidity of the tissue. The course of  $H_2O$  absorption is paralleled by that of the synthesis of org. materials. A. G. P.

**Effects of light on carotenoid formation in tomato fruits.** O. SMITH (Cornell Univ. Agric. Exp. Sta. Mem., 1936, No. 187, 26 pp.).—The carotenoid content of greenhouse-grown fruit is > of that grown outdoors; that of the skin is higher in winter-grown and of the flesh in summer-grown fruit. Strong light favours the production of carotene (I); less intense light produces more lycopene (II). Fruit grown in complete darkness contains more (II) and less (I) than that grown in light. (I) in granular form occurs in plastids and remains after the decomp. of plastids. (II) is not found in plastids but crystals are numerous in the epidermal, plastid-free layer. A. G. P.

**Determination of photosynthetic and respiratory ratios.** B. S. HEYER and D. S. RADER (Plant Physiol., 1936, 11, 437—443).—Appropriate apparatus is described. A. G. P.

**Fluorescence curves of living leaves.** H. KAUTSKY and R. HORMUTH (Naturwiss., 1936, 24, 650—651).—Photographic registration of the fluorescence curves of living leaves indicates the occurrence of four part reactions, all connected with free or combined O. The velocities of the reactions can be calc. from the slopes of the curves. The fluorescence curve is best investigated when the atm. surrounding the leaf is so poor in  $O_2$  that the amount of  $O_2$  dissolved in the chloroplasts is negligible. A. J. M.

**Fluorescent substance present in plants. I. Production of the substance as a result of virus infection: some applications of the phenomenon.** R. J. BEST (Austral. J. Exp. Biol., 1936, 14, 199—213).—In tobacco leaves showing primary lesions of tomato spotted wilt, fluorescent material appears in filtered ultra-violet light. This is caused by a  $H_2O$ -sol., relatively stable org. substance, small amounts of which occur normally in healthy tissue, but which increases in proportion as invasion by the virus proceeds. A. G. P.

**Metastable oxygen and assimilation of carbon dioxide.** H. GAFFRON (Biochem. Z., 1936, 287, 130—139).—The formation of metastable  $O_2$  in photo-oxidations sensitised by chlorophyll could not be demonstrated. P. W. C.

**Yield of green plants in relation to oxygen content of surrounding atmospheres.**—See B., 1936, 1061.

**Growth hormones and development of plants.** N. G. CHOLODNI (Nature, 1936, 138, 586).—Oat seeds soaked in a dil. solution of  $\beta$ -indolylacetic acid before planting produced stronger plants and 55% more grain than untreated seeds. L. S. T.

**Hormonal theory of plant development.** M. C. TSCHAILACHIAN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 443—447).—The processes leading to the sexual development of plants are not determined by the processes of growth and nutrition but are sp. and due to a flowering hormone elaborated in the leaves. E. A. H. R.

**Hormonisation of grains.** N. G. CHOLODNI (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 439—442).—The effect on the normal course of grain crop growth of increasing the hormone content of the embryonic tissue at the commencement of germination is examined. Hormonisation was effected by soaking the dry grain in a solution of  $\beta$ -indolylacetic acid or thrusting it into moist ground with maize endosperm, which is a potent source of auxin. E. A. H. R.

**Plant growth-substances. XXII. Occurrence of biotin in the animal organism.** F. KOGL and W. VAN HASSELT (Z. physiol. Chem., 1936, 243, 189—194; cf. this vol., 1305).—The biotin (I) contents of the organs of the dog, cow, calf, and hen are tabulated. (I) occurs in all the organs examined (except the vitreous humour) in amounts varying from 0.0001 to 1.025 mg. per 100 g. of fresh tissue. The organs of hens contain 3—5 times as much (I) as do those of cattle and dogs. W. McC.

**Effect of crown rust on composition of oats.** H. C. MURPHY (Phytopath., 1936, 26, 220—234).—Infected plants contained larger proportions of insol. solids, ash, N (notably amides,  $NH_3$ ,  $NO_3$ , and  $NO_2$ ), and acid-hydrolysable matter, and less sol. solids, sugar, and dextrin. A. G. P.

**Variations in chief ash constituents of apples affected with blotchy cork.** W. A. DE LONG (Plant Physiol., 1936, 11, 453—456).—The Ca content of affected fruit was > that of healthy controls. A. G. P.

**Comparison of total nitrogen in wheat seeds by the Gunning (modified Kjeldahl) and Dumas methods.** W. Z. HASSID (J. Amer. Chem. Soc., 1936, 58, 2075).—Contrary to Smyth and Wilson (this vol., 121), the Gunning and Dumas methods give the same val. Results (lit.) showing N-fixation by wheat plants are thus not invalidated (cf. *loc. cit.*). H. B.

**Relative distribution of phosphorus and phosphatase activity in the floral parts of *Nicotiana affinis*, *Petunia*, *Salpiglossis*, and *Gladiolus*.** V. IGNATIEFF (Biochem. J., 1936, 30, 1815—1818).—Phosphatase activity is higher in the sex organs as a whole than in other floral parts. It is particularly marked with *Gladiolus* in the anthers. With the floral parts of *Gladiolus* the total P of the sex organs is also high and is highest in the anthers. P. W. C.

**Biose/monose ratio as a biochemical varietal character in the onion.** B. A. RUBIN (Compt. rend. Acad. Sci. U.R.S.S., 1936, 3, 431—434).—Both in gross sugar content and in the biose/monose ratio differences between varieties of onions are great. Monoses predominate in annual onions and bioses in biennials. E. A. H. R.

**Oil of American black walnut.**—See B., 1936, 1054.

**Rice oil. Soya bean oil foots. Oiticica oil. Kapok seed oil. Seed oils of Cucurbitaceæ. Seed fat of "Yabunikukei," *Cinnamomum pedunculatum*.**—See B., 1936, 1105, 1106.

**Chemical composition of *Ilibiseus sabdariffa*, L., and its cultivation in Eritrea.** A. CASTIGLIONI (Atti R. Accad. Sci. Torino, 1934, 69, I, 97—105; Chem. Zentr., 1936, i, 93).—The calyx contains citric and not (as previously stated) tartaric acid. A. G. P.

**Constituents of the seeds of *Digitalis lanata*, Ehrh.** K. SZAHLENDER (Arch. Pharm., 1936, 274, 446—449).—The ground seeds on cold pressing yield 16% of an oil having  $d_4^{20}$  0.922, butyro-refractometer no. 76.0, acid val. 8.0, sap. val. 187, I val. 130. The residue yields digitonin and a bitter *glucoside*, hydrolysed (HCl, EtOH) to a *genin*, m.p. about 245°.

F. R. G.

**Hemicellulose constituents of lucerne roots.** B. A. BURKHART (Plant Physiol., 1936, 11, 421—428).—Separation and fractionation of the hemicelluloses of xylem and phloem of the roots is described. The principal sugars in all fractions were *d*-xylose (I) and *d*-glucose. Some *d*-glycuronic acid (II) was also present. The (I) content was higher in xylem tissue and that of (II) in the phloem. A. G. P.

**Carbohydrates in *Irideæ laminaroides* (Rhodophyceæ).** W. Z. HASSID (Plant Physiol., 1936, 11, 461—463; cf. this vol., 1933).—Further examination of *I. laminaroides* showed the presence of starch and a sulphuric ester of galactan, but no cellulose.

A. G. P.

**Biochemical study of Salicaceæ.** J. RABATÉ (J. Pharm. Chim., 1936, [viii], 24, 363—367).—The isolation of salicoside from the leaves (0.23 g. per 100 g. of fresh leaves; sucrose is also present), bark, and twigs (0.8 g. per 100 g.) of *S. pentandra* is described; populoside is also isolated from the twigs, and the presence of a levorotatory, hydrolysable, glucosidic substance, partly pptd. by Saturne's extract and completely pptd. by Mg or Ca defecation, is indicated.

J. W. B.

**Glucosides of the Salicaceæ.** Analytical method. J. RABATÉ (J. Pharm. Chim., 1936, [viii], 24, 311—325).—H<sub>2</sub>O removes the glucoside (I) and tannins from an EtOH extract. Hydrolysis (invertase, emulsin) of (I) is followed polarimetrically after removal of tannins with Pb, Mg, or Ca(OH)<sub>2</sub>. By determining the reducing sugar present, the concn. of (I) is calc. Details are given for the quant. extraction of glucosides from many species. J. L. D.

**Heterosides and essential oils in the Primulaceæ.** A. GORIS and H. CANAL (Bull. Soc. Chim. biol., 1936, 18, 1405—1424; cf. A., 1935, 268, 1041; this vol., 911). A. L.

**Thioglycollic acid as reagent for lignin.**—See this vol., 1515.

**Colorimetric determination of naringin.** E. M. HARVEY and G. L. RYGG (Plant Physiol., 1936, 11, 463—465).—The method is based on the colour produced by FeCl<sub>3</sub> with naringin. H<sub>2</sub>O extracts of fruit tissue are utilised for the determination. Experimental conditions must be carefully standardised.

A. G. P.

**New saponins.** F. BOAS and R. STEUDE (Angew. Bot., 1936, 18, 16—21).—The nature and function of saponins in plants are discussed. The isolation of a saponin from *Avena sativa* and a hæmolytic saponin from *Medicago falcata* is recorded.

A. G. P.

***Alhagi camelorum* (Dshantak) manna.** N. F. IVANOVA (J. Appl. Chem. Russ., 1936, 9, 1661—1663).—The manna contains H<sub>2</sub>O 5.08, ash 5.8, melezitose 47.07, invert sugar 11.64, and sucrose 26.44%.

R. T.

**Carotenoids. III. Isomeride of lutein from furze (*Ulex europæus*).** K. SCHÖN. IV. Carotenoids of *Genista tridentata*. K. SCHÖN and B. MESQUITA (Biochem. J., 1936, 30, 1960—1965, 1966—1969).—III. From the flowers of *U. europæus* and *U. galli* there have been isolated  $\alpha$ - and  $\beta$ -carotene, violaxanthin (I), taraxanthin, hentriacontane, sitosterol, a sterol (II), C<sub>30</sub>H<sub>50</sub>O, m.p. 152—153°, a carotenoid similar to flavoxanthin (III), and an isomeride (IV) of lutein (V), m.p. 205—206° (corr.). (IV) combines with MeOH, changing to a substance, m.p. 199—200°. The flowers of *U. galli* probably contain (III).

IV. The flowers of *G. tridentata* yielded  $\beta$ -carotene (VI),  $\alpha$ -carotene in very small amount, (V) (present as esters; at least 3 esters in the plant), sitosterol, and a sterol, possibly (II). Probably other carotenoids are also present. In furze (I), but in *G. tridentata* (V), is the predominating xanthophyll. In the plant (V) may be related to (VI).

W. McC.

**Carotenoids of fresh-water algæ. II. Carotenoids and production of ionone in *Trentepohlia*.** Erythritol content of the algæ. J. FISCHER (Z. physiol. Chem., 1936, 243, 103—118; cf. this vol., 912).—The pigment of *Trentepohlia* (*iolithus*, *umbrina*, *aurea*) consists chiefly of  $\alpha$ - and  $\beta$ -carotene in the ratio 3 : 7 together with small amounts of the xanthophylls, lutein, zeaxanthin, and an unidentified pigment resembling fucoxanthin. The yield of carotene from dried algæ was about 0.5%. The algæ contain free erythritol (1.3% in dried *T. iolithus* and *aurea*). The dry algæ contain also small amounts of ionone (I) and produce (I) from carotene.

W. McC.

**Carotenoids of the cranberry.** H. WILLSTAEDT (Svensk Kem. Tidskr., 1936, 48, 212—213).—Cranberries (*Vaccinium vitis idæea*, L.) have a total carotenoid content of only  $27 \times 10^{-6}$  g. per litre of berries, in keeping with their low vitamin-A content.

M. H. M. A.

**Colorimetric determination of carotenoids.**—See this vol., 1496.

**Pigments of the oat coleoptile.** G. WARD and H. G. DU BRY (Science, 1936, 84, 247).—The coleoptile of *Avena sativa* possesses the same pigments as the

leaf, but in lower concns. The photosensitive system is associated with the presence of carotenoids.

L. S. T.

**Pigment of the corn poppy (*Papaver rhæas*, L.).** L. SCHMID and H. KORPERTH (Monatsh., 1936, 68, 290—295; cf. A., 1931, 738; 1932, 934).—The fresh blossoms are extracted with 2% HCl-MeOH; the ppt. obtained by addition of Et<sub>2</sub>O to the extract is treated with EtOH to remove mecocyanin, and the residue is purified by repeated pptn. from MeOH by Et<sub>2</sub>O or dil. HCl, thereby giving the *glucoside* (I) as a dark, reddish-violet powder. (I) is hydrolysed by acid or, preferably, by dil. alkali to *p*-OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H; the presence of hexose but no pentose (*loc. cit.*) is indicated. Hydrolysis with HCl gives two products differing in colour and solubility in MeOH; when dried in a high vac. each loses halogen and leaves *aglucone*-A and -B, C<sub>15</sub>H<sub>12</sub>O<sub>6</sub> [not C<sub>15</sub>H<sub>11</sub>O<sub>4</sub>Cl (*loc. cit.*)], -B being derived from -A by the action of acid. Alkaline degradation affords *p*-OH·C<sub>6</sub>H<sub>4</sub>·CO<sub>2</sub>H and possibly protocatechuic acid, but a homogeneous phenolic compound could not be prepared. 1:3:5-C<sub>6</sub>H<sub>3</sub>(OH)<sub>3</sub> does not appear present. Oxidation with HNO<sub>3</sub> affords picric acid and H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. (I) is probably a complex pelargonidin glucoside with firmly retained H<sub>2</sub>O of crystallisation; the name *mecopelargonin* is therefore proposed.

H. W.

**Investigations of extracts of blossoms.** L. SCHMID and M. KORPERTH (Monatsh., 1936, 68, 296—300).—Robinson's scheme (A., 1932, 1296) for the detection of anthocyanidins is extended to the hydrolysates of the crude extracts of blossoms, and to the examination of the extracts with regard to colour, solubility in C<sub>5</sub>H<sub>11</sub>·OH, and coloration with NaOAc or Na<sub>2</sub>CO<sub>3</sub>.

H. W.

**Constituents of the Chinese drug lei-kung-teng [of the plant] *Tripterygium wilfordii*, Hook.** I. Colouring matter and sugar. T. Q. CHOU and P. F. MEI (Chinese J. Physiol., 1936, 10, 529—533).—The drug (used as an insecticide) on extraction with Et<sub>2</sub>O gave a red cryst. substance, *tripterin*, C<sub>25</sub>H<sub>37</sub>O<sub>3</sub>, m.p. 195° (decomp.), and the residue on extraction with EtOH gave glucose, fructose, and dulcitol.

P. W. C.

**Active fish poison from the bark of *Piscidia erythrina*.** F. HAUSCHILD (Arch. Pharm., 1936, 274, 388—392).—The bark contains a substance, m.p. 72°, not identical with those isolated by Danckwortt *et al.* (A., 1934, 1046). It can be hydrolysed (KOH, EtOH) and in its toxicity to fish resembles rotenone, of which it is probably a derivative.

F. R. G.

**Yellow pigment from Sake-Kasu (sake grains).**—See this vol., 1514.

**Semicarbazones of pyrethrins I and II and of pyrethrolone.**—See this vol., 1514.

**Constituents of *Buellia canescens*.**—See this vol., 1514.

**Alkaloids of *Corydalis ambigua*.**—See this vol., 1527.

**Ambaline and ambalinine, new alkaloids from *Pycnarrhena manillensis*, Vidal.**—See this vol., 1527.

**isoErgine and isolysergic acids.**—See this vol., 1527.

**Alkaloids from *Solanum pseudocapsicum*, L.**—See this vol., 1527.

**Improved Feulgen staining technique.** J. A. DE TOMASI (Stain Tech., 1936, 11, 137—144).—Since different samples of fuchsin vary considerably, the use of pure pararosaniline is suggested. K<sub>2</sub>S<sub>2</sub>O<sub>5</sub> is substituted for NaHSO<sub>3</sub> for decolorising. Fast-green is recommended as a counterstain for plant and orange-G for animal tissue.

E. M. W.

**Stable, high-contrast mordant for hæmatoxylin staining.** A. G. LANG (Stain Tech., 1936, 11, 149—151).—The use of Fe<sub>2</sub>(NH<sub>4</sub>)<sub>2</sub>(SO<sub>4</sub>)<sub>4</sub> with H<sub>2</sub>SO<sub>4</sub> and AcOH is recommended.

E. M. W.

**Colloidal silver method for nerve cells and processes, neuroglia, and microglia.** R. STAGE (Stain. Tech., 1936, 11, 155—160).—A method of staining brain tissue with argyrol or silvol is described, the Ag being replaced with Au before reduction.

E. M. W.

**Pinacyanol as supra-vital mitochondrial stain for blood.** D. C. HETHERINGTON (Stain Tech., 1936, 11, 153—154).—Pinacyanol stains mitochondria selectively and almost permanently.

E. M. W.

**Large quartz spectrograph for examination of biological material.**—See this vol., 1480.

**Microcolorimetric apparatus and a method for determination of total blood volume.** J. C. SOMOGYI (Nature, 1936, 138, 763—764).—An arrangement for determining the concn. of weakly coloured solutions contained in a capillary is applied to estimating the total blood vol. of white rats.

L. S. T.

**Open gas-analysis method for metabolic determinations [on animals].** M. ADANT, P. SPEHL, and R. MINNE (Compt. rend. Soc. Biol., 1936, 123, 313—316).

H. G. R.

**Biochemical gravimetric methods. V. Determination of sodium with the torsion balance.** L. JENDRASSIK and L. DZIOBEK (Biochem. Z., 1936, 287, 262—264).—The ppt. obtained in the method of Barber *et al.* (A., 1928, 859) is collected on suitable filter-paper and weighed on a torsion balance. Na in blood-serum and in other biological material may be determined with an average error of about ±1%. The normal K content of blood-serum does not interfere. The serum should be deproteinised with CCl<sub>3</sub>·CO<sub>2</sub>H; when UO<sub>2</sub>(OAc)<sub>2</sub> is used the results are inaccurate.

W. McC.

**Determination of residual nitrogen and of its fractions and of blood-phenols in the Folin-Wu filtrate by the step photometer.** F. BOHM and G. GRUNER (Biochem. Z., 1936, 287, 65—70).—Modifications of older methods for determination by the step photometer of uric acid, NH<sub>2</sub>-acids, and creatinine and new methods for determination of urea and blood-phenols are described.
